

# **K61 Sub-Family Reference Manual with Addendum**

Rev. 4 of the K61 Sub-Family Reference Manual has two parts:

- The addendum to revision 3 of the reference manual, immediately following this cover page.
- Revision 3 of the reference manual, following the addendum. The changes described in the addendum have not been implemented in the specified pages.

# Addendum to Rev. 3 of the K61 Sub-Family Reference Manual

This addendum identifies changes to Rev. 3 of the K61 Sub-Family Reference Manual for 144-pin package. The changes described in this addendum have not been implemented in the specified pages.

## 1 Remove SDR and DDR controller description from Memories and memory interface table

**Location:** [Section 2.2.3, Page 71](#)

144-pin package of K61 Sub-Family does not support DDR controller and SDR DRAM controller. The rows describing DDR controller and SDR DRAM controller should be removed from Memories and memory interface table.

## 2 Add missing ADC2 and ADC3 Channel Assignment for 144-pin package

**Location:** [Section 3.7.1.5, Page 135](#)

Add the following ADC2 and ADC3 channel assignment for 144-pin package.

**Table 2-1. ADC2 Channel Assignment for 144-Pin Package**

| ADC Channel (SC1n[ADCH]) | Channel | Input signal (SC1n[DIFF]=1)        | Input signal (SC1n[DIFF]=0) |
|--------------------------|---------|------------------------------------|-----------------------------|
| 00000                    | DAD0    | ADC2_DP0 and ADC2_DM0 <sup>1</sup> | ADC2_DP0 <sup>2</sup>       |
| 00001                    | DAD1    | Reserved                           | Reserved                    |
| 00010                    | DAD2    | PGA2_DP and PGA2_DM                | PGA2_DP                     |
| 00011                    | DAD3    | ADC2_DP3 and ADC2_DM3 <sup>3</sup> | ADC2_DP3 <sup>4</sup>       |
| 00100 <sup>5</sup>       | AD4a    | Reserved                           | ADC2_SE4a                   |

### 3 Add 32-bit-read burst-inhibited to 8-bit port (no wait states) topic in Flexbus chapter

|                  |   |
|------------------|---|
| <b>Location:</b> | <a href="#">Section 33.4.12.5, Page 911</a> |
|------------------|---|

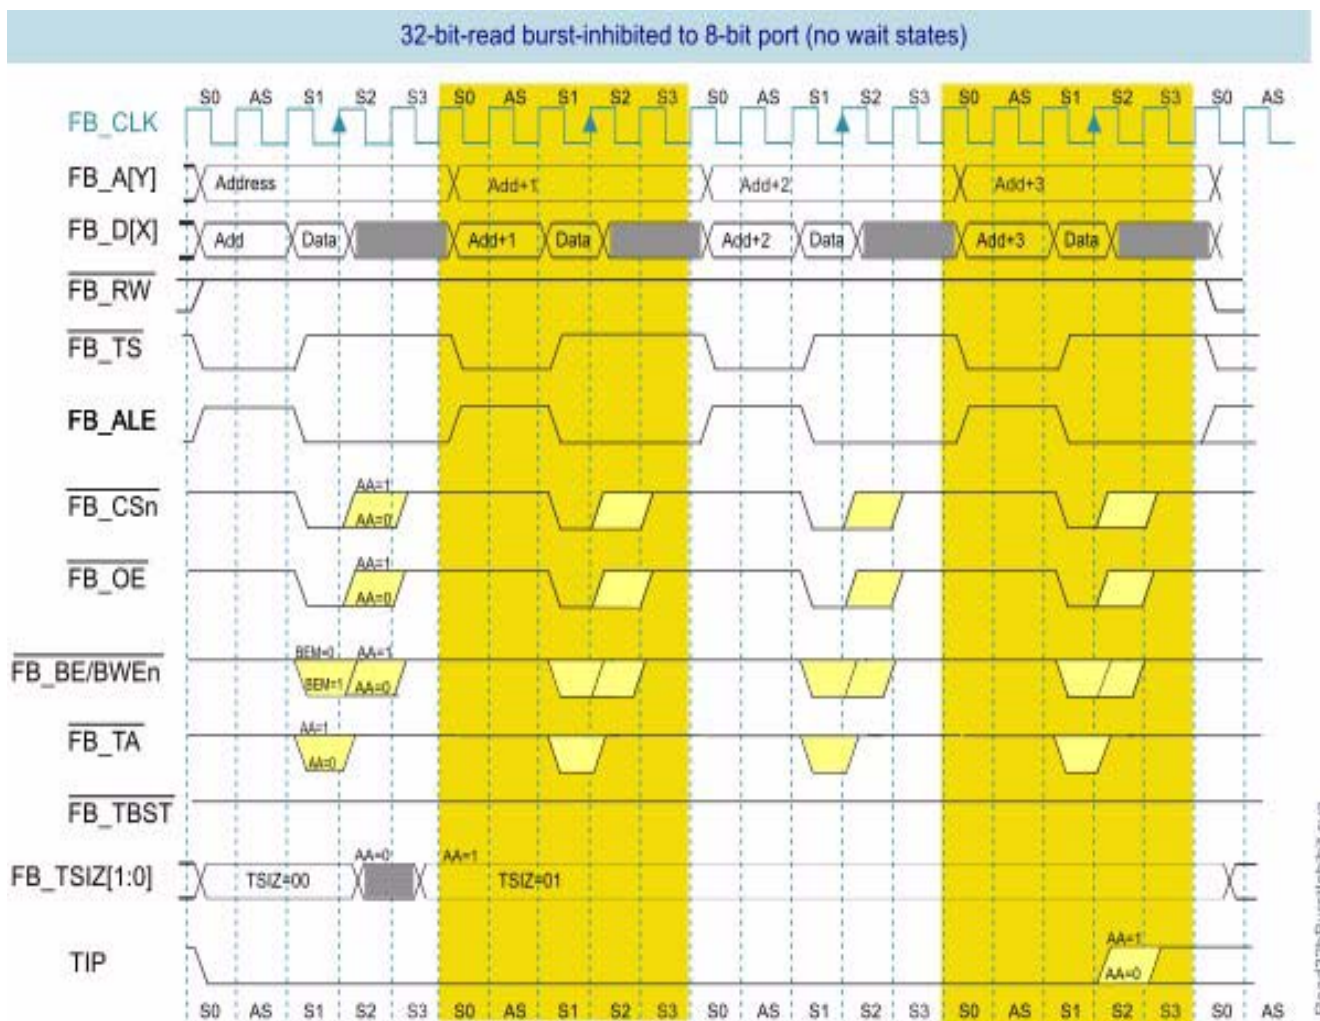

Add the following 32-bit-read burst-inhibited to 8-port (no wait states) topic with diagram.

#### 32-bit-read burst-inhibited to 8-port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

**NOTE**

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1

## 4 Update Flash size from 256 KB to 512KB in Chapter 30 - Flash Memory Module (FTFE)

**Location:** [Chapter 30, Page 749](#)

The flash memory module on this device supports an optional FlexNVM block of 512KB. Some settings in the rev. 3 manual were configured for a 256KB size FlexNVM block instead of 512KB. The updated

chapter with the updates in Table 30-2 EEPROM Data Set Size Field Description, Table 30-4 FlexNVM partition code field description, Flash protection section, Table 30-71 Valid FlexNVM Partition Codes etc. is attached to the addendum.

Click the “attachment” icon on the bottom left of the PDF to see the updated chapter.

## 5 Update the references of ECC bytes to spare bytes in NFC\_SECSZ register

**Location:** [Chapter 32.3.12, Page 851](#)

Sector size register should be as follows:

### Sector Size (NFC\_SECSZ)

Address : 400A\_8000h base + 3F2C h offset = 400A\_BF2Ch

Access: Read/Write

**Figure 1. Sector size register (NFC\_SECSZ)**

**Table 3. NFC\_SECSZ field descriptions**

| Field             | Description   |
|-------------------|---|
| 31-13<br>Reserved | This read-only field is reserved and always has the value zero.   |
| 0<br>CS           | <p>Size in bytes of one elementary transfer unit<br/>For devices with pages of 2KB and smaller, this is the physical size of the page in bytes (data bytes + spare bytes) transferred in one page. When pages are larger than 2KB, they must be split in multiple virtual pages. In this case, the sector size is the size of the virtual page. The virtual page size is the physical size divided by the splitting factor, NFC_CFG[PAGECNT].</p> <p><b>Note:</b> If only a part of a page to be programmed or read, SIZE can be set to the number of affected bytes, not the page size. Then, spare bytes and DMA (data bytes) are all performed on the number of bytes, indicated by SIZE. When performs multiple sections in a page to be programmed, ECC feature can only be enabled at the last section. This will result in failure read access when spare bytes were written with overlapped ECC bytes.</p> <p><b>Note:</b> For 16-bit data width flash devices, only odd SIZE is supported. If SIZE is even number, the real implemented size is SIZE – 1. So, write size + 1 to this field. For example, if SIZE = 1, no data is written or read.</p> <p><b>Note:</b> When programming NAND memory using the ECC feature, ensure that SIZE is equal to number of data + spare bytes (it includes the ECC bytes).</p> |

## 6 Update the references of ECC bytes to spare bytes in Organization of the Data in the NAND Flash

|                  |  |
|------------------|--|
| <b>Location:</b> | <a href="#">Section 32.4.5, Page 866</a> |
|------------------|--|

Update the section as follows to modify the use of ECC bytes by spare bytes.

“Pages on the flash can be split into multiple smaller virtual Spare + Main pages. The parameter that controls this is NFC\_CFG[PAGECNT]. This parameter gives the number of virtual ECC/DMA pages in one flash page. See Section 32.3.13, “Flash Configuration Register (NFC\_CFG)” for more details. The virtual page is split into a user (main) area and spare (includes ECC bytes) area. Data in the user area can be set or used by the application, while data in the spare area is set and used by the ECC and other software information text. ....”

## 7 Add the missing PORT registers for digital filters

|                  |  |
|------------------|--|
| <b>Location:</b> | <a href="#">Section 11.5.5, Page 302</a> |
|------------------|--|

Add the following registers in PORT Control and Interrupts chapter : PORTx\_DFER, PORTx\_DFCR and PORT x\_DFWR.

### Digital Filter Enable Register (PORTx\_DFER)

The digital filter configuration is valid in all digital pin muxing modes.

Address Access: Read/Write  
 PORTA\_DFER is 4004\_9000h base + C0h offset = 4004\_90C0h  
 PORTB\_DFER is 4004\_A000h base + C0h offset = 4004\_A0C0h  
 PORTC\_DFER is 4004\_B000h base + C0h offset = 4004\_B0C0h  
 PORTD\_DFER is 4004\_C000h base + C0h offset = 4004\_C0C0h  
 PORTE\_DFER is 4004\_D000h base + C0h offset = 4004\_D0C0h  
 PORTF\_DFER is 4004\_E000h base + C0h offset = 4004\_E0C0h

**Figure 2. Digital Filter Port Register (PORTx\_DFER)**

**Table 4. PORTx\_DFER field descriptions**

| Field       | Description  |
|-------------|--|
| 31-0<br>DFE | <p>Digital Filter Enable</p> <p>The digital filter configuration is valid in all digital pin muxing modes. The output of each digital filter is reset to zero at system reset and whenever the digital filter is disabled.</p> <p>0 Digital Filter is disabled on the corresponding pin and output of the digital filter is reset to zero. Each bit in the field enables the digital filter of the same number as the bit</p> <p>1 Digital Filter is enabled on the corresponding pin, provided pin is configured as a digital input</p> |

**Digital Filter Enable Register (PORTx\_DFCR)**

The digital filter configuration is valid in all digital pin muxing modes.

**Add the missing PORT registers for digital filters**

Address

Access: Read/Write

PORTA\_DFCR is 4004\_9000h base + C4h offset = 4004\_90C4h  
 PORTB\_DFCR is 4004\_A000h base + C4h offset = 4004\_A0C4h

| 31-1<br>Reserved | This read-only field is reserved and always has the value zero.  |
| 0<br>FILT        | Filter Length<br><br>The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches (in clock cycles) the digital filter absorbs for enabled digital filters. Glitches that are longer than this register setting (in clock cycles) will pass through the digital filter, while glitches that are equal to or less than this register setting (in clock cycles) will be filtered. Changing the filter length should only be done after disabling all enabled filters |

## Chapter 10 Signal Multiplexing and Signal Descriptions

|        |  |     |
|--------|--|-----|
| 10.1   | Introduction.....                                | 261 |
| 10.2   | Signal Multiplexing Integration.....             | 261 |
| 10.2.1 | Port control and interrupt module features.....  | 262 |
| 10.2.2 | PCRn reset values for port A.....                | 262 |
| 10.2.3 | Clock gating.....                                | 262 |
| 10.2.4 | Signal multiplexing constraints.....             | 262 |
| 10.3   | Pinout.....                                      | 263 |
| 10.3.1 | K61 Signal Multiplexing and Pin Assignments..... | 263 |
| 10.3.2 | K61 Pinouts.....                                 | 270 |
| 10.4   | Module Signal Description Tables.....            | 271 |
| 10.4.1 | Core Modules.....                                | 271 |
| 10.4.2 | System Modules.....                              | 272 |
| 10.4.3 | Clock Modules.....                               | 273 |
| 10.4.4 | Memories and Memory Interfaces.....              | 273 |
| 10.4.5 | Security Modules.....                            | 276 |
| 10.4.6 | Analog.....                                      | 276 |
| 10.4.7 | Timer Modules.....                               | 277 |
| 10.4.8 | Communication Interfaces.....                    | 280 |
| 10.4.9 | Human-Machine Interfaces (HMI).....              | 288 |

| Section number                            | Title  | Page |
|---|--|------|
| <b>Chapter 11</b>                         |  |      |
| <b>Port Control and Interrupts (PORT)</b> |  |      |
| 11.1                                      | Introduction.....  | 289  |
| 11.2                                      | Overview.....  | 289  |
| 11.2.1                                    | Features.....  | 289  |
| 11.2.2                                    | Modes of operation.....  | 290  |
| 11.3                                      | External signal description.....                                   | 291  |
| 11.4                                      | Detailed signal description.....                                   | 291  |
| 11.5                                      | Memory map and register definition.....                            | 291  |
| 11.5.1                                    | Pin Control Register n (PORT <sub>x</sub> _PCR <sub>n</sub> )..... | 298  |
| 11.5.2                                    | Global Pin Control Low Register (PORT <sub>x</sub> _GPCLR).....    | 301  |
| 11.5.3                                    | Global Pin Control High Register (PORT <sub>x</sub> _GPCHR).....   | 301  |
| 11.5.4                                    | Interrupt Status Flag Register (PORT <sub>x</sub> _ISFR).....      | 302  |
| 11.6                                      | Functional description.....  | 302  |
| 11.6.1                                    | Pin control.....   | 302  |
| 11.6.2                                    | Global pin control.....  | 303  |
| 11.6.3                                    | External interrupts.....   | 304  |
| <b>Chapter 12</b>                         |  |      |
| <b>System integration module (SIM)</b>    |  |      |
| 12.1                                      | Introduction.....  | 305  |
| 12.1.1                                    | Features.....  | 305  |
| 12.1.2                                    | Modes of operation.....  | 305  |
| 12.2                                      | Memory Map and Registers.....                                      | 306  |
| 12.2.1                                    | System Options Register 1 (SIM_SOPT1).....                         | 307  |
| 12.2.2                                    | SOPT1 Configuration Register (SIM_SOPT1CFG).....                   | 309  |
| 12.2.3                                    | System Options Register 2 (SIM_SOPT2).....                         | 310  |
| 12.2.4                                    | System Options Register 4 (SIM_SOPT4).....                         | 313  |
| 12.2.5                                    | System Options Register 5 (SIM_SOPT5).....                         | 316  |
| 12.2.6                                    | System Options Register 6 (SIM_SOPT6).....                         | 317  |

| Section number | Title  | Page |
|----------------|--|------|
| 12.2.7         | System Options Register 7 (SIM_SOPT7).....               | 318  |
| 12.2.8         | System Device Identification Register (SIM_SDID).....    | 321  |
| 12.2.9         | System Clock Gating Control Register 1 (SIM_SCGC1).....  | 323  |
| 12.2.10        | System Clock Gating Control Register 2 (SIM_SCGC2).....  | 324  |
| 12.2.11        | System Clock Gating Control Register 3 (SIM_SCGC3).....  | 325  |
| 12.2.12        | System Clock Gating Control Register 4 (SIM_SCGC4).....  | 327  |
| 12.2.13        | System Clock Gating Control Register 5 (SIM_SCGC5).....  | 329  |
| 12.2.14        | System Clock Gating Control Register 6 (SIM_SCGC6).....  | 331  |
| 12.2.15        | System Clock Gating Control Register 7 (SIM_SCGC7).....  | 333  |
| 12.2.16        | System Clock Divider Register 1 (SIM_CLKDIV1).....       | 334  |
| 12.2.17        | System Clock Divider Register 2 (SIM_CLKDIV2).....       | 336  |
| 12.2.18        | Flash Configuration Register 1 (SIM_FCFG1).....          | 337  |
| 12.2.19        | Flash Configuration Register 2 (SIM_FCFG2).....          | 340  |
| 12.2.20        | Unique Identification Register High (SIM_UIDH).....      | 341  |
| 12.2.21        | Unique Identification Register Mid-High (SIM_UIDMH)..... | 342  |
| 12.2.22        | Unique Identification Register Mid Low (SIM_UIDML).....  | 342  |
| 12.2.23        | Unique Identification Register Low (SIM_UIDL).....       | 343  |
| 12.2.24        | System Clock Divider Register 4 (SIM_CLKDIV4).....       | 343  |
| 12.2.25        | Misc Control Register (SIM_MCR).....                     | 344  |

## Chapter 13 Reset Control Module (RCM)

|        |   |     |
|--------|---|-----|
| 13.1   | Introduction.....                                 | 347 |
| 13.2   | Reset memory map and register descriptions.....   | 347 |
| 13.2.1 | System Reset Status Register 0 (RCM_SRS0).....    | 348 |
| 13.2.2 | System Reset Status Register 1 (RCM_SRS1).....    | 349 |
| 13.2.3 | Reset Pin Filter Control register (RCM_RPFC)..... | 351 |
| 13.2.4 | Reset Pin Filter Width register (RCM_RPFW).....   | 352 |
| 13.2.5 | Mode Register (RCM_MR).....                       | 353 |

| <b>Chapter 14</b>                        |  |      |
| <b>System Mode Controller (SMC)</b>      |  |      |
| 14.1                                     | Introduction.....  | 355  |
| 14.2                                     | Modes of operation.....  | 355  |
| 14.3                                     | Memory map and register descriptions.....                          | 357  |
| 14.3.1                                   | Power Mode Protection register (SMC_PMPROT).....                   | 358  |
| 14.3.2                                   | Power Mode Control register (SMC_PMCTRL).....                      | 359  |
| 14.3.3                                   | VLLS Control Register (SMC_VLLSCTRL).....                          | 361  |
| 14.3.4                                   | Power Mode Status register (SMC_PMSTAT).....                       | 362  |
| 14.4                                     | Functional description.....  | 362  |
| 14.4.1                                   | Power mode transitions.....  | 362  |
| 14.4.2                                   | Power mode entry/exit sequencing.....                              | 365  |
| 14.4.3                                   | Run modes.....   | 368  |
| 14.4.4                                   | Wait modes.....  | 369  |
| 14.4.5                                   | Stop modes.....  | 370  |
| 14.4.6                                   | Debug in low power modes.....                                      | 373  |
| <b>Chapter 15</b>                        |  |      |
| <b>Power Management Controller (PMC)</b> |  |      |
| 15.1                                     | Introduction.....  | 375  |
| 15.2                                     | Features.....  | 375  |
| 15.3                                     | Low-voltage detect (LVD) system.....                               | 375  |
| 15.3.1                                   | LVD reset operation.....   | 376  |
| 15.3.2                                   | LVD interrupt operation.....                                       | 376  |
| 15.3.3                                   | Low-voltage warning (LVW) interrupt operation.....                 | 376  |
| 15.4                                     | I/O retention.....   | 377  |
| 15.5                                     | Memory map and register descriptions.....                          | 377  |
| 15.5.1                                   | Low Voltage Detect Status And Control 1 register (PMC_LVDSC1)..... | 378  |
| 15.5.2                                   | Low Voltage Detect Status And Control 2 register (PMC_LVDSC2)..... | 379  |
| 15.5.3                                   | Regulator Status And Control register (PMC_REGSC).....             | 380  |

| <b>Chapter 16</b>                     |  |      |
| <b>Low-Leakage Wakeup Unit (LLWU)</b> |  |      |
| 16.1                                  | Introduction.....                            | 383  |
| 16.1.1                                | Features.....                                | 383  |
| 16.1.2                                | Modes of operation.....                      | 384  |
| 16.1.3                                | Block diagram.....                           | 385  |
| 16.2                                  | LLWU signal descriptions.....                | 386  |
| 16.3                                  | Memory map/register definition.....          | 386  |
| 16.3.1                                | LLWU Pin Enable 1 register (LLWU_PE1).....   | 387  |
| 16.3.2                                | LLWU Pin Enable 2 register (LLWU_PE2).....   | 388  |
| 16.3.3                                | LLWU Pin Enable 3 register (LLWU_PE3).....   | 389  |
| 16.3.4                                | LLWU Pin Enable 4 register (LLWU_PE4).....   | 390  |
| 16.3.5                                | LLWU Module Enable register (LLWU_ME).....   | 391  |
| 16.3.6                                | LLWU Flag 1 register (LLWU_F1).....          | 393  |
| 16.3.7                                | LLWU Flag 2 register (LLWU_F2).....          | 395  |
| 16.3.8                                | LLWU Flag 3 register (LLWU_F3).....          | 396  |
| 16.3.9                                | LLWU Pin Filter 1 register (LLWU_FILT1)..... | 398  |
| 16.3.10                               | LLWU Pin Filter 2 register (LLWU_FILT2)..... | 399  |
| 16.3.11                               | LLWU Reset Enable register (LLWU_RST).....   | 400  |
| 16.4                                  | Functional description.....                  | 401  |
| 16.4.1                                | LLS mode.....                                | 401  |
| 16.4.2                                | VLLS modes.....                              | 402  |
| 16.4.3                                | Initialization.....                          | 402  |

**Chapter 17**  
**Miscellaneous Control Module (MCM)**

|        |   |     |
|--------|---|-----|
| 17.1   | Introduction.....   | 403 |
| 17.1.1 | Features.....   | 403 |
| 17.2   | Memory map/register descriptions.....                       | 403 |
| 17.2.1 | Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)..... | 404 |

| Section number | Title  | Page |
|----------------|--|------|
| 17.2.2         | Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)..... | 405  |
| 17.2.3         | Control Register (MCM_CR).....                               | 405  |
| 17.2.4         | Interrupt Status and Control Register (MCM_ISCR).....        | 407  |
| 17.2.5         | ETB Counter Control register (MCM_ETBCC).....                | 410  |
| 17.2.6         | ETB Reload register (MCM_ETBRL).....                         | 411  |
| 17.2.7         | ETB Counter Value register (MCM_ETBCNT).....                 | 412  |
| 17.2.8         | Fault address register (MCM_FADR).....                       | 412  |
| 17.2.9         | Fault attributes register (MCM_FATR).....                    | 413  |
| 17.2.10        | Fault data register (MCM_FDR).....                           | 415  |
| 17.2.11        | Process ID register (MCM_PID).....                           | 416  |
| 17.3           | Functional description.....                                  | 416  |
| 17.3.1         | Interrupts.....  | 416  |

## Chapter 18 Crossbar Switch (AXBS)

|        |  |     |
|--------|--|-----|
| 18.1   | Introduction.....  | 419 |
| 18.1.1 | Features.....  | 419 |
| 18.2   | Memory Map / Register Definition.....                      | 420 |
| 18.2.1 | Priority Registers Slave (AXBS_PRSn).....                  | 421 |
| 18.2.2 | Control Register (AXBS_CRSn).....                          | 424 |
| 18.2.3 | Master General Purpose Control Register (AXBS_MGPCRn)..... | 426 |
| 18.3   | Functional Description.....                                | 426 |
| 18.3.1 | General operation.....                                     | 426 |
| 18.3.2 | Register coherency.....                                    | 428 |
| 18.3.3 | Arbitration.....   | 428 |
| 18.4   | Initialization/application information.....                | 431 |

## Chapter 19 Memory Protection Unit (MPU)

|      |                   |     |
|------|-------------------|-----|
| 19.1 | Introduction..... | 433 |
|------|-------------------|-----|

| Section number | Title  | Page |
|----------------|--|------|
| 19.2           | Overview.....  | 433  |
| 19.2.1         | Block diagram.....   | 433  |
| 19.2.2         | Features.....  | 434  |
| 19.3           | Memory map/register definition.....  | 435  |
| 19.3.1         | Control/Error Status Register (MPU_CESR).....                                | 439  |
| 19.3.2         | Error Address Register, slave port n (MPU_EAR <sub>n</sub> ).....            | 440  |
| 19.3.3         | Error Detail Register, slave port n (MPU_EDR <sub>n</sub> ).....             | 441  |
| 19.3.4         | Region Descriptor n, Word 0 (MPU_RGD <sub>n</sub> _WORD0).....               | 442  |
| 19.3.5         | Region Descriptor n, Word 1 (MPU_RGD <sub>n</sub> _WORD1).....               | 443  |
| 19.3.6         | Region Descriptor n, Word 2 (MPU_RGD <sub>n</sub> _WORD2).....               | 443  |
| 19.3.7         | Region Descriptor n, Word 3 (MPU_RGD <sub>n</sub> _WORD3).....               | 446  |
| 19.3.8         | Region Descriptor Alternate Access Control n (MPU_RGDAAC <sub>n</sub> )..... | 447  |
| 19.4           | Functional description.....  | 449  |
| 19.4.1         | Access evaluation macro.....   | 449  |
| 19.4.2         | Putting it all together and error terminations.....                          | 451  |
| 19.4.3         | Power management.....  | 451  |
| 19.5           | Initialization information.....  | 452  |
| 19.6           | Application information.....   | 452  |

## Chapter 20 Peripheral Bridge (AIPS-Lite)

|        |   |     |
|--------|---|-----|
| 20.1   | Introduction.....   | 455 |
| 20.1.1 | Features.....   | 455 |
| 20.1.2 | General operation.....  | 455 |
| 20.2   | Memory map/register definition.....   | 456 |
| 20.2.1 | Master Privilege Register A (AIPS <sub>x</sub> _MPRA).....                      | 457 |
| 20.2.2 | Peripheral Access Control Register (AIPS <sub>x</sub> _PACR <sub>n</sub> )..... | 461 |
| 20.2.3 | Peripheral Access Control Register (AIPS <sub>x</sub> _PACR <sub>n</sub> )..... | 467 |
| 20.3   | Functional description.....   | 471 |
| 20.3.1 | Access support.....   | 471 |

| Section number                                   | Title   | Page |
|--|---|------|
| <b>Chapter 21</b>                                |   |      |
| <b>Direct Memory Access Multiplexer (DMAMUX)</b> |   |      |
| 21.1   | Introduction.....                                     | 473  |
| 21.1.1   | Overview.....   | 473  |
| 21.1.2   | Features.....   | 474  |
| 21.1.3   | Modes of operation.....                               | 474  |
| 21.2   | External signal description.....                      | 475  |
| 21.3   | Memory map/register definition.....                   | 475  |
| 21.3.1   | Channel Configuration register (DMAMUXx_CHCFGn).....  | 476  |
| 21.4   | Functional description.....                           | 477  |
| 21.4.1   | DMA channels with periodic triggering capability..... | 477  |
| 21.4.2   | DMA channels with no triggering capability.....       | 480  |
| 21.4.3   | Always-enabled DMA sources.....                       | 480  |
| 21.5   | Initialization/application information.....           | 481  |
| 21.5.1   | Reset.....  | 481  |
| 21.5.2   | Enabling and configuring sources.....                 | 481  |
| <b>Chapter 22</b>                                |   |      |
| <b>Enhanced Direct Memory Access (eDMA)</b>      |   |      |
| 22.1   | Introduction.....                                     | 485  |
| 22.1.1   | eDMA system block diagram.....                        | 485  |
| 22.1.2   | Block parts.....                                      | 486  |
| 22.1.3   | Features.....   | 487  |
| 22.2   | Modes of operation.....                               | 489  |
| 22.3   | Memory map/register definition.....                   | 489  |
| 22.3.1   | TCD memory.....                                       | 489  |
| 22.3.2   | TCD initialization.....                               | 490  |
| 22.3.3   | TCD structure.....                                    | 490  |
| 22.3.4   | Reserved memory and bit fields.....                   | 492  |
| 22.3.1   | Control Register (DMA_CR).....                        | 515  |

| Section number | Title   | Page |
|----------------|---|------|
| 22.3.2         | Error Status Register (DMA_ES).....   | 518  |
| 22.3.3         | Enable Request Register (DMA_ERQ).....  | 520  |
| 22.3.4         | Enable Error Interrupt Register (DMA_EEI).....  | 524  |
| 22.3.5         | Clear Enable Error Interrupt Register (DMA_CEEI).....   | 527  |
| 22.3.6         | Set Enable Error Interrupt Register (DMA_SEEI).....   | 528  |
| 22.3.7         | Clear Enable Request Register (DMA_CERQ).....   | 529  |
| 22.3.8         | Set Enable Request Register (DMA_SERQ).....   | 530  |
| 22.3.9         | Clear DONE Status Bit Register (DMA_CDNE).....  | 531  |
| 22.3.10        | Set START Bit Register (DMA_SSRT).....  | 532  |
| 22.3.11        | Clear Error Register (DMA_CERR).....  | 533  |
| 22.3.12        | Clear Interrupt Request Register (DMA_CINT).....  | 534  |
| 22.3.13        | Interrupt Request Register (DMA_INT).....   | 535  |
| 22.3.14        | Error Register (DMA_ERR).....   | 538  |
| 22.3.15        | Hardware Request Status Register (DMA_HRS).....   | 542  |
| 22.3.16        | Enable Asynchronous Request in Stop Register (DMA_EARS).....  | 548  |
| 22.3.17        | Channel n Priority Register (DMA_DCHPRIn).....  | 551  |
| 22.3.18        | TCD Source Address (DMA_TCDn_SADDR).....  | 552  |
| 22.3.19        | TCD Signed Source Address Offset (DMA_TCDn_SOFF).....   | 553  |
| 22.3.20        | TCD Transfer Attributes (DMA_TCDn_ATTR).....  | 553  |
| 22.3.21        | TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCDn_NBYTES_MLNO).....                                    | 554  |
| 22.3.22        | TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled)<br>(DMA_TCDn_NBYTES_MLOFFNO).....   | 555  |
| 22.3.23        | TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled)<br>(DMA_TCDn_NBYTES_MLOFFYES).....           | 556  |
| 22.3.24        | TCD Last Source Address Adjustment (DMA_TCDn_SLAST).....  | 558  |
| 22.3.25        | TCD Destination Address (DMA_TCDn_DADDR).....   | 558  |
| 22.3.26        | TCD Signed Destination Address Offset (DMA_TCDn_DOFF).....  | 559  |
| 22.3.27        | TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled)<br>(DMA_TCDn_CITER_ELINKYES)..... | 559  |

| Section number | Title   | Page |
|----------------|---|------|
| 22.3.28        | TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled)<br>(DMA_TCDn_CITER_ELINKNO).....   | 560  |
| 22.3.29        | TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCDn_DLASTSGA).....                     | 561  |
| 22.3.30        | TCD Control and Status (DMA_TCDn_CSR).....  | 562  |
| 22.3.31        | TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled)<br>(DMA_TCDn_BITER_ELINKYES)..... | 564  |
| 22.3.32        | TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled)<br>(DMA_TCDn_BITER_ELINKNO)..... | 565  |
| 22.4           | Functional description.....   | 566  |
| 22.4.1         | eDMA basic data flow.....   | 566  |
| 22.4.2         | Fault reporting and handling.....   | 569  |
| 22.4.3         | Channel preemption.....   | 571  |
| 22.4.4         | Performance.....  | 572  |
| 22.5           | Initialization/application information.....   | 576  |
| 22.5.1         | eDMA initialization.....  | 576  |
| 22.5.2         | Programming errors.....   | 578  |
| 22.5.3         | Arbitration mode considerations.....  | 579  |
| 22.5.4         | Performing DMA transfers.....   | 580  |
| 22.5.5         | Monitoring transfer descriptor status.....  | 584  |
| 22.5.6         | Channel Linking.....  | 586  |
| 22.5.7         | Dynamic programming.....  | 587  |

## Chapter 23 External Watchdog Monitor (EWM)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 23.1   | Introduction.....                   | 593 |
| 23.1.1 | Features.....                       | 593 |
| 23.1.2 | Modes of Operation.....             | 594 |
| 23.1.3 | Block Diagram.....                  | 595 |
| 23.2   | EWM Signal Descriptions.....        | 596 |
| 23.3   | Memory Map/Register Definition..... | 596 |
| 23.3.1 | Control Register (EWM_CTRL).....    | 596 |

| Section number | Title                                 | Page |
|----------------|---------------------------------------|------|
| 23.3.2         | Service Register (EWM_SERV).....      | 597  |
| 23.3.3         | Compare Low Register (EWM_CMPL).....  | 597  |
| 23.3.4         | Compare High Register (EWM_CMPH)..... | 598  |
| 23.4           | Functional Description.....           | 599  |
| 23.4.1         | The EWM_out Signal.....               | 599  |
| 23.4.2         | The EWM_in Signal.....                | 600  |
| 23.4.3         | EWM Counter.....                      | 600  |
| 23.4.4         | EWM Compare Registers.....            | 600  |
| 23.4.5         | EWM Refresh Mechanism.....            | 601  |
| 23.4.6         | EWM Interrupt.....                    | 601  |

## Chapter 24 Watchdog Timer (WDOG)

|        |   |     |
|--------|---|-----|
| 24.1   | Introduction.....   | 603 |
| 24.2   | Features.....   | 603 |
| 24.3   | Functional overview.....                                      | 605 |
| 24.3.1 | Unlocking and updating the watchdog.....                      | 606 |
| 24.3.2 | Watchdog configuration time (WCT).....                        | 607 |
| 24.3.3 | Refreshing the watchdog.....                                  | 608 |
| 24.3.4 | Windowed mode of operation.....                               | 608 |
| 24.3.5 | Watchdog disabled mode of operation.....                      | 608 |
| 24.3.6 | Low-power modes of operation.....                             | 609 |
| 24.3.7 | Debug modes of operation.....                                 | 609 |
| 24.4   | Testing the watchdog.....                                     | 610 |
| 24.4.1 | Quick test.....   | 611 |
| 24.4.2 | Byte test.....  | 611 |
| 24.5   | Backup reset generator.....                                   | 612 |
| 24.6   | Generated resets and interrupts.....                          | 612 |
| 24.7   | Memory map and register definition.....                       | 613 |
| 24.7.1 | Watchdog Status and Control Register High (WDOG_STCTRLH)..... | 614 |

| Section number | Title  | Page |
|----------------|--|------|
| 24.7.2         | Watchdog Status and Control Register Low (WDOG_STCTRL) | 615  |
| 24.7.3         | Watchdog Time-out Value Register High (WDOG_TOVALH)    | 616  |
| 24.7.4         | Watchdog Time-out Value Register Low (WDOG_TOVALL)     | 616  |
| 24.7.5         | Watchdog Window Register High (WDOG_WINH)              | 617  |
| 24.7.6         | Watchdog Window Register Low (WDOG_WINL)               | 617  |
| 24.7.7         | Watchdog Refresh register (WDOG_REFRESH)               | 618  |
| 24.7.8         | Watchdog Unlock register (WDOG_UNLOCK)                 | 618  |
| 24.7.9         | Watchdog Timer Output Register High (WDOG_TMROUTH)     | 618  |
| 24.7.10        | Watchdog Timer Output Register Low (WDOG_TMROUTL)      | 619  |
| 24.7.11        | Watchdog Reset Count register (WDOG_RSTCNT)            | 619  |
| 24.7.12        | Watchdog Prescaler register (WDOG_PRESC)               | 620  |
| 24.8           | Watchdog operation with 8-bit access                   | 620  |
| 24.8.1         | General guideline                                      | 620  |
| 24.8.2         | Refresh and unlock operations with 8-bit access        | 620  |
| 24.9           | Restrictions on watchdog operation                     | 621  |

## Chapter 25 Multipurpose Clock Generator (MCG)

|        |                                 |     |
|--------|---------------------------------|-----|
| 25.1   | Introduction                    | 625 |
| 25.1.1 | Features                        | 625 |
| 25.1.2 | Modes of Operation              | 629 |
| 25.2   | External Signal Description     | 629 |
| 25.3   | Memory Map/Register Definition  | 629 |
| 25.3.1 | MCG Control 1 Register (MCG_C1) | 630 |
| 25.3.2 | MCG Control 2 Register (MCG_C2) | 631 |
| 25.3.3 | MCG Control 3 Register (MCG_C3) | 632 |
| 25.3.4 | MCG Control 4 Register (MCG_C4) | 633 |
| 25.3.5 | MCG Control 5 Register (MCG_C5) | 634 |
| 25.3.6 | MCG Control 6 Register (MCG_C6) | 636 |
| 25.3.7 | MCG Status Register (MCG_S)     | 637 |

| Section number | Title  | Page |
|----------------|--|------|
| 25.3.8         | MCG Status and Control Register (MCG_SC).....              | 638  |
| 25.3.9         | MCG Auto Trim Compare Value High Register (MCG_ATCVH)..... | 640  |
| 25.3.10        | MCG Auto Trim Compare Value Low Register (MCG_ATCVL).....  | 640  |
| 25.3.11        | MCG Control 7 Register (MCG_C7).....                       | 640  |
| 25.3.12        | MCG Control 8 Register (MCG_C8).....                       | 641  |
| 25.3.13        | MCG Control 10 Register (MCG_C10).....                     | 642  |
| 25.3.14        | MCG Control 11 Register (MCG_C11).....                     | 643  |
| 25.3.15        | MCG Control 12 Register (MCG_C12).....                     | 644  |
| 25.3.16        | MCG Status 2 Register (MCG_S2).....                        | 645  |
| 25.4           | Functional description.....                                | 647  |
| 25.4.1         | MCG mode state diagram.....                                | 647  |
| 25.4.2         | Low-power bit usage.....                                   | 652  |
| 25.4.3         | MCG Internal Reference Clocks.....                         | 652  |
| 25.4.4         | External Reference Clock.....                              | 652  |
| 25.4.5         | MCG Fixed Frequency Clock .....                            | 653  |
| 25.4.6         | MCG PLL clock .....  | 653  |
| 25.4.7         | MCG Auto TRIM (ATM).....                                   | 654  |
| 25.5           | Initialization / Application information.....              | 655  |
| 25.5.1         | MCG module initialization sequence.....                    | 655  |
| 25.5.2         | Using a 32.768 kHz reference.....                          | 657  |
| 25.5.3         | MCG mode switching.....                                    | 658  |

## Chapter 26 Oscillator (OSC)

|      |   |     |
|------|---|-----|
| 26.1 | Introduction.....                             | 669 |
| 26.2 | Features and Modes.....                       | 669 |
| 26.3 | Block Diagram.....                            | 670 |
| 26.4 | OSC Signal Descriptions.....                  | 670 |
| 26.5 | External Crystal / Resonator Connections..... | 671 |
| 26.6 | External Clock Connections.....               | 672 |

| Section number | Title                                   | Page |
|----------------|---|------|
| 26.7           | Memory Map/Register Definitions.....    | 673  |
| 26.7.1         | OSC Memory Map/Register Definition..... | 673  |
| 26.8           | Functional Description.....             | 674  |
| 26.8.1         | OSC module states.....                  | 674  |
| 26.8.2         | OSC module modes.....                   | 676  |
| 26.8.3         | Counter.....                            | 678  |
| 26.8.4         | Reference clock pin requirements.....   | 678  |
| 26.9           | Reset.....                              | 678  |
| 26.10          | Low power modes operation.....          | 679  |
| 26.11          | Interrupts.....                         | 679  |

## Chapter 27 RTC Oscillator (OSC32K)

|        |                                       |     |
|--------|---------------------------------------|-----|
| 27.1   | Introduction.....                     | 681 |
| 27.1.1 | Features and Modes.....               | 681 |
| 27.1.2 | Block Diagram.....                    | 681 |
| 27.2   | RTC Signal Descriptions.....          | 682 |
| 27.2.1 | EXTAL32 — Oscillator Input.....       | 682 |
| 27.2.2 | XTAL32 — Oscillator Output.....       | 682 |
| 27.3   | External Crystal Connections.....     | 683 |
| 27.4   | Memory Map/Register Descriptions..... | 683 |
| 27.5   | Functional Description.....           | 683 |
| 27.6   | Reset Overview.....                   | 684 |
| 27.7   | Interrupts.....                       | 684 |

## Chapter 28 Local Memory Controller

|        |                     |     |
|--------|---------------------|-----|
| 28.1   | Introduction.....   | 685 |
| 28.1.1 | Block Diagram.....  | 685 |
| 28.1.2 | Cache features..... | 686 |

| Section number | Title  | Page |
|----------------|--|------|
| 28.2           | Memory Map/Register Definition.....                | 688  |
| 28.2.1         | Cache control register (LMEM_PCCCR).....           | 688  |
| 28.2.2         | Cache line control register (LMEM_PCCLCR).....     | 690  |
| 28.2.3         | Cache search address register (LMEM_PCCSAR).....   | 692  |
| 28.2.4         | Cache read/write value register (LMEM_PCCCVR)..... | 693  |
| 28.2.5         | Cache regions mode register (LMEM_PCCRM).....      | 693  |
| 28.2.6         | Cache control register (LMEM_PSCCR).....           | 697  |
| 28.2.7         | Cache line control register (LMEM_PSCLCR).....     | 698  |
| 28.2.8         | Cache search address register (LMEM_PSCSAR).....   | 701  |
| 28.2.9         | Cache read/write value register (LMEM_PSCCVR)..... | 702  |
| 28.2.10        | Cache regions mode register (LMEM_PSCRM).....      | 702  |
| 28.3           | Functional Description.....                        | 705  |
| 28.3.1         | LMEM Function.....                                 | 705  |
| 28.3.2         | SRAM Function.....                                 | 706  |
| 28.3.3         | Cache Function.....                                | 709  |
| 28.3.4         | Cache Control.....                                 | 710  |

## Chapter 29 Flash Memory Controller (FMC)

|        |  |     |
|--------|--|-----|
| 29.1   | Introduction.....                                  | 717 |
| 29.1.1 | Overview.....                                      | 717 |
| 29.1.2 | Features.....                                      | 718 |
| 29.2   | Modes of operation.....                            | 718 |
| 29.3   | External signal description.....                   | 718 |
| 29.4   | Memory map and register descriptions.....          | 718 |
| 29.4.1 | Flash Access Protection Register (FMC_PFAPR).....  | 724 |
| 29.4.2 | Flash Bank 0-1 Control Register (FMC_PFB01CR)..... | 727 |
| 29.4.3 | Flash Bank 2-3 Control Register (FMC_PFB23CR)..... | 730 |
| 29.4.4 | Cache Tag Storage (FMC_TAGVDW0Sn).....             | 732 |
| 29.4.5 | Cache Tag Storage (FMC_TAGVDW1Sn).....             | 733 |

| Section number   | Title   | Page |
|--|---|------|
| 29.4.6   | Cache Tag Storage (FMC_TAGVDW2Sn).....                    | 734  |
| 29.4.7   | Cache Tag Storage (FMC_TAGVDW3Sn).....                    | 735  |
| 29.4.8   | Cache Data Storage (uppermost word) (FMC_DATAW0SnUM)..... | 736  |
| 29.4.9   | Cache Data Storage (mid-upper word) (FMC_DATAW0SnMU)..... | 736  |
| 29.4.10  | Cache Data Storage (mid-lower word) (FMC_DATAW0SnML)..... | 737  |
| 29.4.11  | Cache Data Storage (lowermost word) (FMC_DATAW0SnLM)..... | 737  |
| 29.4.12  | Cache Data Storage (uppermost word) (FMC_DATAW1SnUM)..... | 738  |
| 29.4.13  | Cache Data Storage (mid-upper word) (FMC_DATAW1SnMU)..... | 738  |
| 29.4.14  | Cache Data Storage (mid-lower word) (FMC_DATAW1SnML)..... | 739  |
| 29.4.15  | Cache Data Storage (lowermost word) (FMC_DATAW1SnLM)..... | 739  |
| 29.4.16  | Cache Data Storage (uppermost word) (FMC_DATAW2SnUM)..... | 740  |
| 29.4.17  | Cache Data Storage (mid-upper word) (FMC_DATAW2SnMU)..... | 740  |
| 29.4.18  | Cache Data Storage (mid-lower word) (FMC_DATAW2SnML)..... | 741  |
| 29.4.19  | Cache Data Storage (lowermost word) (FMC_DATAW2SnLM)..... | 741  |
| 29.4.20  | Cache Data Storage (uppermost word) (FMC_DATAW3SnUM)..... | 742  |
| 29.4.21  | Cache Data Storage (mid-upper word) (FMC_DATAW3SnMU)..... | 742  |
| 29.4.22  | Cache Data Storage (mid-lower word) (FMC_DATAW3SnML)..... | 743  |
| 29.4.23  | Cache Data Storage (lowermost word) (FMC_DATAW3SnLM)..... | 743  |
| 29.5   | Functional description.....                               | 744  |
| 29.5.1   | Default configuration.....                                | 744  |
| 29.5.2   | Configuration options.....                                | 744  |
| 29.5.3   | Wait states.....  | 745  |
| 29.5.4   | Speculative reads.....                                    | 746  |
| 29.6   | Initialization and application information.....           | 746  |
| <br><b>Chapter 30</b><br><b>Flash Memory Module (FTFE)</b><br><br> |   |      |
| 30.1   | Introduction.....   | 749  |

| 31.2.2         | EzPort Chip Select (EZP_CS).....        | 828  |
| 31.2.3         | EzPort Serial Data In (EZP_D).....      | 828  |
| 31.2.4         | EzPort Serial Data Out (EZP_Q).....     | 828  |
| 31.3           | Command definition.....                 | 828  |
| 31.3.1         | Command descriptions.....               | 829  |
| 31.4           | Flash memory map for EzPort access..... | 839  |

## Chapter 32 NAND Flash Controller (NFC)

|         |  |     |
|---------|--|-----|
| 32.1    | Introduction.....                        | 841 |
| 32.1.1  | Block Diagram.....                       | 842 |
| 32.1.2  | Features.....                            | 842 |
| 32.2    | External Signal Description.....         | 843 |
| 32.3    | Memory Map/Register Definition.....      | 844 |
| 32.3.1  | Flash command 1 (NFC_CMD1).....          | 844 |
| 32.3.2  | Flash command 2 (NFC_CMD2).....          | 845 |
| 32.3.3  | Column address (NFC_CAR).....            | 846 |
| 32.3.4  | Row address (NFC_RAR).....               | 846 |
| 32.3.5  | Flash command repeat (NFC_RPT).....      | 847 |
| 32.3.6  | Row address increment (NFC_RAI).....     | 848 |
| 32.3.7  | Flash status 1 (NFC_SR1).....            | 848 |
| 32.3.8  | Flash status 2 (NFC_SR2).....            | 849 |
| 32.3.9  | DMA channel 1 address (NFC_DMA_CH1)..... | 849 |
| 32.3.10 | DMA configuration (NFC_DMACFG).....      | 850 |
| 32.3.11 | Cach swap (NFC_SWAP).....                | 850 |
| 32.3.12 | Sector size (NFC_SECSZ).....             | 851 |
| 32.3.13 | Flash configuration (NFC_CFG).....       | 852 |
| 32.3.14 | DMA channel 2 address (NFC_DMA_CH2)..... | 854 |

| Section number | Title   | Page |
|----------------|---|------|
| 32.3.15        | Interrupt status (NFC_ISR).....                 | 855  |
| 32.4           | Functional Description.....                     | 856  |
| 32.4.1         | NFC Buffer Memory Space.....                    | 857  |
| 32.4.2         | Error Corrector Status.....                     | 858  |
| 32.4.3         | NFC Basic Commands.....                         | 859  |
| 32.4.4         | Fast Flash Configuration for EDO.....           | 865  |
| 32.4.5         | Organization of the Data in the NAND Flash..... | 866  |
| 32.4.6         | Flash Command Code Description.....             | 870  |
| 32.4.7         | Interrupts.....                                 | 871  |

## Chapter 33 External Bus Interface (FlexBus)

|        |   |     |
|--------|---|-----|
| 33.1   | Introduction.....   | 873 |
| 33.1.1 | Definition.....   | 873 |
| 33.1.2 | Features.....   | 873 |
| 33.2   | Signal descriptions.....  | 874 |
| 33.3   | Memory Map/Register Definition.....                             | 877 |
| 33.3.1 | Chip Select Address Register (FB_CSAR $n$ ).....                | 878 |
| 33.3.2 | Chip Select Mask Register (FB_CSMR $n$ ).....                   | 879 |
| 33.3.3 | Chip Select Control Register (FB_CSCR $n$ ).....                | 880 |
| 33.3.4 | Chip Select port Multiplexing Control Register (FB_CSPMCR)..... | 883 |
| 33.4   | Functional description.....                                     | 884 |
| 33.4.1 | Modes of operation.....   | 884 |
| 33.4.2 | Address comparison.....   | 885 |
| 33.4.3 | Address driven on address bus.....                              | 885 |
| 33.4.4 | Connecting address/data lines.....                              | 885 |
| 33.4.5 | Bit ordering.....   | 886 |
| 33.4.6 | Data transfer signals.....                                      | 886 |
| 33.4.7 | Signal transitions.....   | 886 |
| 33.4.8 | Data-byte alignment and physical connections.....               | 886 |

| Section number | Title   | Page |
|----------------|---|------|
| 33.4.9         | Address/data bus multiplexing.....                | 888  |
| 33.4.10        | Data transfer states.....                         | 889  |
| 33.4.11        | FlexBus Timing Examples.....                      | 889  |
| 33.4.12        | Burst cycles.....                                 | 908  |
| 33.4.13        | Extended Transfer Start/Address Latch Enable..... | 916  |
| 33.4.14        | Bus errors.....                                   | 917  |
| 33.5           | Initialization/Application Information.....       | 918  |
| 33.5.1         | Initializing a chip-select.....                   | 918  |
| 33.5.2         | Reconfiguring a chip-select.....                  | 918  |

## Chapter 34 Cyclic Redundancy Check (CRC)

|        |   |     |
|--------|---|-----|
| 34.1   | Introduction.....                         | 919 |
| 34.1.1 | Features.....                             | 919 |
| 34.1.2 | Block diagram.....                        | 919 |
| 34.1.3 | Modes of operation.....                   | 920 |
| 34.2   | Memory map and register descriptions..... | 920 |
| 34.2.1 | CRC Data register (CRC_DATA).....         | 921 |
| 34.2.2 | CRC Polynomial register (CRC_GPOLY).....  | 922 |
| 34.2.3 | CRC Control register (CRC_CTRL).....      | 922 |
| 34.3   | Functional description.....               | 923 |
| 34.3.1 | CRC initialization/reinitialization.....  | 923 |
| 34.3.2 | CRC calculations.....                     | 924 |
| 34.3.3 | Transpose feature.....                    | 925 |
| 34.3.4 | CRC result complement.....                | 927 |

## Chapter 35 Cryptographic Acceleration Unit (CAU)

|      |                        |     |
|------|------------------------|-----|
| 35.1 | Introduction.....      | 929 |
| 35.2 | CAU Block Diagram..... | 929 |
| 35.3 | Overview.....          | 931 |

| Section number | Title                                       | Page |
|----------------|---|------|
| 35.4           | Features.....                               | 932  |
| 35.5           | Memory map/Register definition.....         | 932  |
| 35.5.1         | Status Register (CAU_CASR).....             | 934  |
| 35.5.2         | Accumulator (CAU_CAA).....                  | 935  |
| 35.5.3         | General Purpose Register (CAU_CAn).....     | 935  |
| 35.6           | Functional description.....                 | 936  |
| 35.6.1         | CAU programming model.....                  | 936  |
| 35.6.2         | CAU integrity checks.....                   | 938  |
| 35.6.3         | CAU commands.....                           | 940  |
| 35.7           | Application/initialization information..... | 947  |
| 35.7.1         | Code example.....                           | 947  |
| 35.7.2         | Assembler equate values.....                | 948  |

## Chapter 36 Random Number Generator Accelerator (RNGA)

|        |   |     |
|--------|---|-----|
| 36.1   | Introduction.....                           | 951 |
| 36.1.1 | Overview.....                               | 951 |
| 36.2   | Modes of operation.....                     | 952 |
| 36.2.1 | Entering Normal mode.....                   | 952 |
| 36.2.2 | Entering Sleep mode.....                    | 952 |
| 36.3   | Memory map and register definition.....     | 953 |
| 36.3.1 | RNGA Control Register (RNG_CR).....         | 953 |
| 36.3.2 | RNGA Status Register (RNG_SR).....          | 955 |
| 36.3.3 | RNGA Entropy Register (RNG_ER).....         | 957 |
| 36.3.4 | RNGA Output Register (RNG_OR).....          | 957 |
| 36.4   | Functional description.....                 | 958 |
| 36.4.1 | Output (OR) register.....                   | 958 |
| 36.4.2 | Core engine / control logic.....            | 958 |
| 36.5   | Initialization/application information..... | 959 |

| Section number                           | Title   | Page |
|--|---|------|
| <b>Chapter 37</b>                        |   |      |
| <b>Analog-to-Digital Converter (ADC)</b> |   |      |
| 37.1                                     | Introduction.....   | 961  |
| 37.1.1                                   | Features.....   | 961  |
| 37.1.2                                   | Block diagram.....  | 962  |
| 37.2                                     | ADC signal descriptions.....                                      | 963  |
| 37.2.1                                   | Analog Power (VDDA).....  | 964  |
| 37.2.2                                   | Analog Ground (VSSA).....   | 964  |
| 37.2.3                                   | Voltage Reference Select.....                                     | 964  |
| 37.2.4                                   | Analog Channel Inputs (ADx).....                                  | 965  |
| 37.2.5                                   | Differential Analog Channel Inputs (DADx).....                    | 965  |
| 37.3                                     | Memory map and register definitions.....                          | 965  |
| 37.3.1                                   | ADC Status and Control Registers 1 (ADCx_SC1n).....               | 970  |
| 37.3.2                                   | ADC Configuration Register 1 (ADCx_CFG1).....                     | 973  |
| 37.3.3                                   | ADC Configuration Register 2 (ADCx_CFG2).....                     | 974  |
| 37.3.4                                   | ADC Data Result Register (ADCx_Rn).....                           | 975  |
| 37.3.5                                   | Compare Value Registers (ADCx_CVn).....                           | 977  |
| 37.3.6                                   | Status and Control Register 2 (ADCx_SC2).....                     | 978  |
| 37.3.7                                   | Status and Control Register 3 (ADCx_SC3).....                     | 980  |
| 37.3.8                                   | ADC Offset Correction Register (ADCx_OFS).....                    | 981  |
| 37.3.9                                   | ADC Plus-Side Gain Register (ADCx_PG).....                        | 982  |
| 37.3.10                                  | ADC Minus-Side Gain Register (ADCx_MG).....                       | 982  |
| 37.3.11                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLPD)..... | 983  |
| 37.3.12                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLPS)..... | 984  |
| 37.3.13                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLP4)..... | 984  |
| 37.3.14                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLP3)..... | 985  |
| 37.3.15                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLP2)..... | 985  |
| 37.3.16                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLP1)..... | 986  |
| 37.3.17                                  | ADC Plus-Side General Calibration Value Register (ADCx_CLP0)..... | 986  |

| Section number | Title  | Page |
|----------------|--|------|
| 37.3.18        | ADC PGA Register (ADCx_PGA).....                                   | 987  |
| 37.3.19        | ADC Minus-Side General Calibration Value Register (ADCx_CLMD)..... | 988  |
| 37.3.20        | ADC Minus-Side General Calibration Value Register (ADCx_CLMS)..... | 989  |
| 37.3.21        | ADC Minus-Side General Calibration Value Register (ADCx_CLM4)..... | 989  |
| 37.3.22        | ADC Minus-Side General Calibration Value Register (ADCx_CLM3)..... | 990  |
| 37.3.23        | ADC Minus-Side General Calibration Value Register (ADCx_CLM2)..... | 990  |
| 37.3.24        | ADC Minus-Side General Calibration Value Register (ADCx_CLM1)..... | 991  |
| 37.3.25        | ADC Minus-Side General Calibration Value Register (ADCx_CLM0)..... | 991  |
| 37.4           | Functional description.....  | 992  |
| 37.4.1         | PGA functional description.....                                    | 992  |
| 37.4.2         | Clock select and divide control.....                               | 994  |
| 37.4.3         | Voltage reference selection.....                                   | 994  |
| 37.4.4         | Hardware trigger and channel selects.....                          | 995  |
| 37.4.5         | Conversion control.....  | 996  |
| 37.4.6         | Automatic compare function.....                                    | 1004 |
| 37.4.7         | Calibration function.....  | 1005 |
| 37.4.8         | User-defined offset function.....                                  | 1007 |
| 37.4.9         | Temperature sensor.....  | 1008 |
| 37.4.10        | MCU wait mode operation.....                                       | 1008 |
| 37.4.11        | MCU Normal Stop mode operation.....                                | 1009 |
| 37.4.12        | MCU Low-Power Stop mode operation.....                             | 1010 |

| Section number | Title                                  | Page |
|----------------|--|------|
| 37.5           | Initialization information.....        | 1010 |
| 37.5.1         | ADC module initialization example..... | 1011 |
| 37.6           | Application information.....           | 1013 |
| 37.6.1         | External pins and routing.....         | 1013 |
| 37.6.2         | Sources of error.....                  | 1015 |

## Chapter 38 Comparator (CMP)

|        |   |      |
|--------|---|------|
| 38.1   | Introduction.....                               | 1019 |
| 38.1.1 | CMP features.....                               | 1019 |
| 38.1.2 | 6-bit DAC key features.....                     | 1020 |
| 38.1.3 | ANMUX key features.....                         | 1020 |
| 38.1.4 | CMP, DAC and ANMUX diagram.....                 | 1021 |
| 38.1.5 | CMP block diagram.....                          | 1022 |
| 38.2   | Memory map/register definitions.....            | 1024 |
| 38.2.1 | CMP Control Register 0 (CMPx_CR0).....          | 1025 |
| 38.2.2 | CMP Control Register 1 (CMPx_CR1).....          | 1026 |

## Chapter 39 12-bit Digital-to-Analog Converter (DAC)

|        |  |      |
|--------|--|------|
| 39.1   | Introduction.....                        | 1047 |
| 39.2   | Features.....                            | 1047 |
| 39.3   | Block diagram.....                       | 1047 |
| 39.4   | Memory map/register definition.....      | 1048 |
| 39.4.1 | DAC Data Low Register (DACx_DATnL).....  | 1051 |
| 39.4.2 | DAC Data High Register (DACx_DATnH)..... | 1051 |
| 39.4.3 | DAC Status Register (DACx_SR).....       | 1052 |
| 39.4.4 | DAC Control Register (DACx_C0).....      | 1053 |
| 39.4.5 | DAC Control Register 1 (DACx_C1).....    | 1054 |
| 39.4.6 | DAC Control Register 2 (DACx_C2).....    | 1055 |
| 39.5   | Functional description.....              | 1055 |
| 39.5.1 | DAC data buffer operation.....           | 1055 |
| 39.5.2 | DMA operation.....                       | 1057 |
| 39.5.3 | Resets.....                              | 1057 |
| 39.5.4 | Low-Power mode operation.....            | 1057 |

## Chapter 40 Voltage Reference (VREFV1)

|        |                               |      |
|--------|-------------------------------|------|
| 40.1   | Introduction.....             | 1059 |
| 40.1.1 | Overview.....                 | 1060 |
| 40.1.2 | Features.....                 | 1060 |
| 40.1.3 | Modes of Operation.....       | 1061 |
| 40.1.4 | VREF Signal Descriptions..... | 1061 |

| Section number | Title   | Page |
|----------------|---|------|
| 40.2           | Memory Map and Register Definition.....         | 1062 |
| 40.2.1         | VREF Trim Register (VREF_TRM).....              | 1062 |
| 40.2.2         | VREF Status and Control Register (VREF_SC)..... | 1063 |
| 40.3           | Functional Description.....                     | 1064 |
| 40.3.1         | Voltage Reference Disabled, SC[VREFEN] = 0..... | 1064 |
| 40.3.2         | Voltage Reference Enabled, SC[VREFEN] = 1.....  | 1064 |
| 40.4           | Initialization/Application Information.....     | 1065 |

## Chapter 41 Programmable Delay Block (PDB)

|         |  |      |
|---------|--|------|
| 41.1    | Introduction.....  | 1067 |
| 41.1.1  | Features.....  | 1067 |
| 41.1.2  | Implementation.....  | 1068 |
| 41.1.3  | Back-to-back acknowledgment connections.....   | 1069 |
| 41.1.4  | DAC External Trigger Input Connections.....  | 1069 |
| 41.1.5  | Block diagram.....   | 1069 |
| 41.1.6  | Modes of operation.....  | 1071 |
| 41.2    | PDB signal descriptions.....   | 1071 |
| 41.3    | Memory map and register definition.....  | 1071 |
| 41.3.1  | Status and Control register (PDB <sub>x</sub> _SC).....                                | 1073 |
| 41.3.2  | Modulus register (PDB <sub>x</sub> _MOD).....  | 1075 |
| 41.3.3  | Counter register (PDB <sub>x</sub> _CNT).....  | 1076 |
| 41.3.4  | Interrupt Delay register (PDB <sub>x</sub> _IDLY).....                                 | 1076 |
| 41.3.5  | Channel n Control register 1 (PDB <sub>x</sub> _CH <sub>n</sub> C1).....               | 1077 |
| 41.3.6  | Channel n Status register (PDB <sub>x</sub> _CH <sub>n</sub> S).....                   | 1078 |
| 41.3.7  | Channel n Delay 0 register (PDB <sub>x</sub> _CH <sub>n</sub> DLY0).....               | 1078 |
| 41.3.8  | Channel n Delay 1 register (PDB <sub>x</sub> _CH <sub>n</sub> DLY1).....               | 1079 |
| 41.3.9  | DAC Interval Trigger n Control register (PDB <sub>x</sub> _DACINTC <sub>n</sub> )..... | 1079 |
| 41.3.10 | DAC Interval n register (PDB <sub>x</sub> _DACINT <sub>n</sub> ).....                  | 1080 |
| 41.3.11 | Pulse-Out n Enable register (PDB <sub>x</sub> _POEN).....                              | 1080 |

| Section number | Title   | Page |
|----------------|---|------|
| 41.3.12        | Pulse-Out n Delay register (PDBx_POnDLY).....                                     | 1081 |
| 41.4           | Functional description.....   | 1081 |
| 41.4.1         | PDB pre-trigger and trigger outputs.....  | 1081 |
| 41.4.2         | PDB trigger input source selection.....   | 1083 |
| 41.4.3         | DAC interval trigger outputs.....   | 1083 |
| 41.4.4         | Pulse-Out's.....  | 1084 |
| 41.4.5         | Updating the delay registers.....   | 1084 |
| 41.4.6         | Interrupts.....   | 1086 |
| 41.4.7         | DMA.....  | 1086 |
| 41.5           | Application information.....  | 1087 |
| 41.5.1         | Impact of using the prescaler and multiplication factor on timing resolution..... | 1087 |

## Chapter 42 FlexTimer Module (FTM)

|        |   |      |
|--------|---|------|
| 42.1   | Introduction.....                               | 1089 |
| 42.1.1 | FlexTimer philosophy.....                       | 1089 |
| 42.1.2 | Features.....                                   | 1090 |
| 42.1.3 | Modes of operation.....                         | 1091 |
| 42.1.4 | Block diagram.....                              | 1092 |
| 42.2   | FTM signal descriptions.....                    | 1094 |
| 42.3   | Memory map and register definition.....         | 1094 |
| 42.3.1 | Memory map.....                                 | 1094 |
| 42.3.2 | Register descriptions.....                      | 1095 |
| 42.3.3 | Status And Control (FTMx_SC).....               | 1101 |
| 42.3.4 | Counter (FTMx_CNT).....                         | 1102 |
| 42.3.5 | Modulo (FTMx_MOD).....                          | 1103 |
| 42.3.6 | Channel (n) Status And Control (FTMx_CnSC)..... | 1104 |
| 42.3.7 | Channel (n) Value (FTMx_CnV).....               | 1106 |
| 42.3.8 | Counter Initial Value (FTMx_CNTIN).....         | 1107 |
| 42.3.9 | Capture And Compare Status (FTMx_STATUS).....   | 1107 |

| Section number | Title   | Page |
|----------------|---|------|
| 42.3.10        | Features Mode Selection (FTM <sub>x</sub> _MODE).....                 | 1109 |
| 42.3.11        | Synchronization (FTM <sub>x</sub> _SYNC).....                         | 1111 |
| 42.3.12        | Initial State For Channels Output (FTM <sub>x</sub> _OUTINIT).....    | 1114 |
| 42.3.13        | Output Mask (FTM <sub>x</sub> _OUTMASK).....                          | 1115 |
| 42.3.14        | Function For Linked Channels (FTM <sub>x</sub> _COMBINE).....         | 1117 |
| 42.3.15        | Deadtime Insertion Control (FTM <sub>x</sub> _DEADTIME).....          | 1122 |
| 42.3.16        | FTM External Trigger (FTM <sub>x</sub> _EXTTRIG).....                 | 1123 |
| 42.3.17        | Channels Polarity (FTM <sub>x</sub> _POL).....                        | 1125 |
| 42.3.18        | Fault Mode Status (FTM <sub>x</sub> _FMS).....                        | 1127 |
| 42.3.19        | Input Capture Filter Control (FTM <sub>x</sub> _FILTER).....          | 1129 |
| 42.3.20        | Fault Control (FTM <sub>x</sub> _FLTCTRL).....                        | 1130 |
| 42.3.21        | Quadrature Decoder Control And Status (FTM <sub>x</sub> _QDCTRL)..... | 1132 |
| 42.3.22        | Configuration (FTM <sub>x</sub> _CONF).....                           | 1134 |
| 42.3.23        | FTM Fault Input Polarity (FTM <sub>x</sub> _FLTPOL).....              | 1135 |
| 42.3.24        | Synchronization Configuration (FTM <sub>x</sub> _SYNCONF).....        | 1137 |
| 42.3.25        | FTM Inverting Control (FTM <sub>x</sub> _INVCTRL).....                | 1139 |
| 42.3.26        | FTM Software Output Control (FTM <sub>x</sub> _SWOCTRL).....          | 1140 |
| 42.3.27        | FTM PWM Load (FTM <sub>x</sub> _PWMLOAD).....                         | 1142 |
| 42.4           | Functional description.....   | 1143 |
| 42.4.1         | Clock source.....   | 1144 |
| 42.4.2         | Prescaler.....  | 1145 |
| 42.4.3         | Counter.....  | 1145 |
| 42.4.4         | Input Capture mode.....   | 1151 |
| 42.4.5         | Output Compare mode.....  | 1153 |
| 42.4.6         | Edge-Aligned PWM (EPWM) mode.....                                     | 1154 |
| 42.4.7         | Center-Aligned PWM (CPWM) mode.....                                   | 1156 |
| 42.4.8         | Combine mode.....   | 1158 |
| 42.4.9         | Complementary mode.....   | 1166 |

| Section number | Title                                     | Page |
|----------------|---|------|
| 42.4.10        | Registers updated from write buffers..... | 1167 |
| 42.4.11        | PWM synchronization.....                  | 1169 |
| 42.4.12        | Inverting.....                            | 1185 |
| 42.4.13        | Software output control.....              | 1186 |
| 42.4.14        | Deadtime insertion.....                   | 1188 |
| 42.4.15        | Output mask.....                          | 1191 |
| 42.4.16        | Fault control.....                        | 1192 |
| 42.4.17        | Polarity control.....                     | 1195 |
| 42.4.18        | Initialization.....                       | 1196 |
| 42.4.19        | Features priority.....                    | 1196 |
| 42.4.20        | Channel trigger output.....               | 1197 |
| 42.4.21        | Initialization trigger.....               | 1198 |
| 42.4.22        | Capture Test mode.....                    | 1200 |
| 42.4.23        | DMA.....                                  | 1201 |
| 42.4.24        | Dual Edge Capture mode.....               | 1202 |
| 42.4.25        | Quadrature Decoder mode.....              | 1209 |
| 42.4.26        | BDM mode.....                             | 1214 |
| 42.4.27        | Intermediate load.....                    | 1215 |
| 42.4.28        | Global time base (GTB).....               | 1217 |
| 42.5           | Reset overview.....                       | 1219 |
| 42.6           | FTM Interrupts.....                       | 1220 |
| 42.6.1         | Timer Overflow Interrupt.....             | 1221 |
| 42.6.2         | Channel (n) Interrupt.....                | 1221 |
| 42.6.3         | Fault Interrupt.....                      | 1221 |
| 42.7           | Initialization Procedure.....             | 1221 |

## Chapter 43 Periodic Interrupt Timer (PIT)

|        |                    |      |
|--------|--------------------|------|
| 43.1   | Introduction.....  | 1223 |
| 43.1.1 | Block diagram..... | 1223 |

| Section number | Title  | Page |
|----------------|--|------|
| 43.1.2         | Features.....  | 1224 |
| 43.2           | Signal description.....                                    | 1224 |
| 43.3           | Memory map/register description.....                       | 1225 |
| 43.3.1         | PIT Module Control Register (PIT_MCR).....                 | 1225 |
| 43.3.2         | Timer Load Value Register (PIT_LDVAL <sub>n</sub> ).....   | 1227 |
| 43.3.3         | Current Timer Value Register (PIT_CVAL <sub>n</sub> )..... | 1227 |
| 43.3.4         | Timer Control Register (PIT_TCTRL <sub>n</sub> ).....      | 1228 |
| 43.3.5         | Timer Flag Register (PIT_TFLG <sub>n</sub> ).....          | 1228 |
| 43.4           | Functional description.....                                | 1229 |
| 43.4.1         | General operation.....                                     | 1229 |
| 43.4.2         | Interrupts.....  | 1231 |
| 43.4.3         | Chained timers.....  | 1231 |
| 43.5           | Initialization and application information.....            | 1231 |
| 43.6           | Example configuration for chained timers.....              | 1232 |

## Chapter 44 Low-Power Timer (LPTMR)

|        |  |      |
|--------|--|------|
| 44.1   | Introduction.....  | 1235 |
| 44.1.1 | Features.....  | 1235 |
| 44.1.2 | Modes of operation.....  | 1235 |
| 44.2   | LPTMR signal descriptions.....   | 1236 |
| 44.2.1 | Detailed signal descriptions.....                                      | 1236 |
| 44.3   | Memory map and register definition.....                                | 1237 |
| 44.3.1 | Low Power Timer Control Status Register (LPTMR <sub>x</sub> _CSR)..... | 1237 |
| 44.3.2 | Low Power Timer Prescale Register (LPTMR <sub>x</sub> _PSR).....       | 1239 |
| 44.3.3 | Low Power Timer Compare Register (LPTMR <sub>x</sub> _CMR).....        | 1240 |
| 44.3.4 | Low Power Timer Counter Register (LPTMR <sub>x</sub> _CNR).....        | 1241 |
| 44.4   | Functional description.....  | 1241 |
| 44.4.1 | LPTMR power and reset.....   | 1241 |
| 44.4.2 | LPTMR clocking.....  | 1241 |

| Section number | Title                              | Page |
|----------------|------------------------------------|------|
| 44.4.3         | LPTMR prescaler/glitch filter..... | 1242 |
| 44.4.4         | LPTMR compare.....                 | 1243 |
| 44.4.5         | LPTMR counter.....                 | 1243 |
| 44.4.6         | LPTMR hardware trigger.....        | 1244 |
| 44.4.7         | LPTMR interrupt.....               | 1244 |

## Chapter 45 Carrier Modulator Transmitter (CMT)

|         |  |      |
|---------|--|------|
| 45.1    | Introduction.....  | 1247 |
| 45.2    | Features.....  | 1247 |
| 45.3    | Block diagram.....   | 1248 |
| 45.4    | Modes of operation.....                                    | 1249 |
| 45.4.1  | Wait mode operation.....                                   | 1250 |
| 45.4.2  | Stop mode operation.....                                   | 1251 |
| 45.5    | CMT external signal descriptions.....                      | 1251 |
| 45.5.1  | CMT_IRO — Infrared Output.....                             | 1251 |
| 45.6    | Memory map/register definition.....                        | 1252 |
| 45.6.1  | CMT Carrier Generator High Data Register 1 (CMT_CGH1)..... | 1253 |
| 45.6.2  | CMT Carrier Generator Low Data Register 1 (CMT_CGL1).....  | 1254 |
| 45.6.3  | CMT Carrier Generator High Data Register 2 (CMT_CGH2)..... | 1254 |
| 45.6.4  | CMT Carrier Generator Low Data Register 2 (CMT_CGL2).....  | 1255 |
| 45.6.5  | CMT Output Control Register (CMT_OC).....                  | 1255 |
| 45.6.6  | CMT Modulator Status and Control Register (CMT_MSC).....   | 1256 |
| 45.6.7  | CMT Modulator Data Register Mark High (CMT_CMD1).....      | 1258 |
| 45.6.8  | CMT Modulator Data Register Mark Low (CMT_CMD2).....       | 1259 |
| 45.6.9  | CMT Modulator Data Register Space High (CMT_CMD3).....     | 1259 |
| 45.6.10 | CMT Modulator Data Register Space Low (CMT_CMD4).....      | 1260 |
| 45.6.11 | CMT Primary Prescaler Register (CMT_PPS).....              | 1260 |
| 45.6.12 | CMT Direct Memory Access Register (CMT_DMA).....           | 1261 |

| Section number | Title                         | Page |
|----------------|-------------------------------|------|
| 45.7           | Functional description.....   | 1262 |
| 45.7.1         | Clock divider.....            | 1262 |
| 45.7.2         | Carrier generator.....        | 1262 |
| 45.7.3         | Modulator.....                | 1265 |
| 45.7.4         | Extended space operation..... | 1269 |
| 45.8           | CMT interrupts and DMA.....   | 1271 |

## Chapter 46 Real Time Clock (RTC)

|         |   |      |
|---------|---|------|
| 46.1    | Introduction.....                                   | 1273 |
| 46.1.1  | Features.....                                       | 1273 |
| 46.1.2  | Modes of operation.....                             | 1273 |
| 46.1.3  | RTC signal descriptions.....                        | 1274 |
| 46.2    | Register definition.....                            | 1275 |
| 46.2.1  | RTC Time Seconds Register (RTC_TSR).....            | 1276 |
| 46.2.2  | RTC Time Prescaler Register (RTC_TPR).....          | 1276 |
| 46.2.3  | RTC Time Alarm Register (RTC_TAR).....              | 1277 |
| 46.2.4  | RTC Time Compensation Register (RTC_TCR).....       | 1277 |
| 46.2.5  | RTC Control Register (RTC_CR).....                  | 1278 |
| 46.2.6  | RTC Status Register (RTC_SR).....                   | 1280 |
| 46.2.7  | RTC Lock Register (RTC_LR).....                     | 1282 |
| 46.2.8  | RTC Interrupt Enable Register (RTC_IER).....        | 1284 |
| 46.2.9  | RTC Tamper Time Seconds Register (RTC_TTSR).....    | 1285 |
| 46.2.10 | RTC Monotonic Enable Register (RTC_MER).....        | 1285 |
| 46.2.11 | RTC Monotonic Counter Low Register (RTC_MCLR).....  | 1286 |
| 46.2.12 | RTC Monotonic Counter High Register (RTC_MCHR)..... | 1286 |
| 46.2.13 | RTC Write Access Register (RTC_WAR).....            | 1287 |
| 46.2.14 | RTC Read Access Register (RTC_RAR).....             | 1289 |

| Section number | Title                           | Page |
|----------------|---------------------------------|------|
| 46.3           | Functional description.....     | 1291 |
| 46.3.1         | Power, clocking, and reset..... | 1291 |
| 46.3.2         | Time counter.....               | 1292 |
| 46.3.3         | Compensation.....               | 1293 |
| 46.3.4         | Time alarm.....                 | 1294 |
| 46.3.5         | Update mode.....                | 1294 |
| 46.3.6         | Monotonic counter.....          | 1294 |
| 46.3.7         | Register lock.....              | 1295 |
| 46.3.8         | Access control.....             | 1295 |
| 46.3.9         | Interrupt.....                  | 1295 |

## Chapter 47 10/100-Mbps Ethernet MAC (ENET)

|         |  |      |
|---------|--|------|
| 47.1    | Introduction.....                                    | 1297 |
| 47.2    | Overview.....  | 1297 |
| 47.2.1  | Features.....  | 1298 |
| 47.2.2  | Block diagram.....                                   | 1300 |
| 47.3    | External signal description.....                     | 1301 |
| 47.4    | Memory map/register definition.....                  | 1303 |
| 47.4.1  | Interrupt Event Register (ENET_EIR).....             | 1308 |
| 47.4.2  | Interrupt Mask Register (ENET_EIMR).....             | 1311 |
| 47.4.3  | Receive Descriptor Active Register (ENET_RDAR).....  | 1314 |
| 47.4.4  | Transmit Descriptor Active Register (ENET_TDAR)..... | 1314 |
| 47.4.5  | Ethernet Control Register (ENET_ECR).....            | 1315 |
| 47.4.6  | MII Management Frame Register (ENET_MMFR).....       | 1317 |
| 47.4.7  | MII Speed Control Register (ENET_MSCR).....          | 1318 |
| 47.4.8  | MIB Control Register (ENET_MIBC).....                | 1320 |
| 47.4.9  | Receive Control Register (ENET_RCR).....             | 1321 |
| 47.4.10 | Transmit Control Register (ENET_TCR).....            | 1324 |
| 47.4.11 | Physical Address Lower Register (ENET_PALR).....     | 1326 |

| Section number | Title   | Page |
|----------------|---|------|
| 47.4.12        | Physical Address Upper Register (ENET_PAUR).....  | 1326 |
| 47.4.13        | Opcode/Pause Duration Register (ENET_OPD).....  | 1327 |
| 47.4.14        | Descriptor Individual Upper Address Register (ENET_IAUR).....                           | 1327 |
| 47.4.15        | Descriptor Individual Lower Address Register (ENET_IALR).....                           | 1328 |
| 47.4.16        | Descriptor Group Upper Address Register (ENET_GAUR).....                                | 1328 |
| 47.4.17        | Descriptor Group Lower Address Register (ENET_GALR).....                                | 1329 |
| 47.4.18        | Transmit FIFO Watermark Register (ENET_TFWR).....                                       | 1329 |
| 47.4.19        | Receive Descriptor Ring Start Register (ENET_RDSR).....                                 | 1330 |
| 47.4.20        | Transmit Buffer Descriptor Ring Start Register (ENET_TDSR).....                         | 1331 |
| 47.4.21        | Maximum Receive Buffer Size Register (ENET_MRBR).....                                   | 1332 |
| 47.4.22        | Receive FIFO Section Full Threshold (ENET_RSFL).....                                    | 1333 |
| 47.4.23        | Receive FIFO Section Empty Threshold (ENET_RSEM).....                                   | 1333 |
| 47.4.24        | Receive FIFO Almost Empty Threshold (ENET_RAEM).....                                    | 1334 |
| 47.4.25        | Receive FIFO Almost Full Threshold (ENET_RAFL).....                                     | 1334 |
| 47.4.26        | Transmit FIFO Section Empty Threshold (ENET_TSEM).....                                  | 1335 |
| 47.4.27        | Transmit FIFO Almost Empty Threshold (ENET_TAEM).....                                   | 1335 |
| 47.4.28        | Transmit FIFO Almost Full Threshold (ENET_TAFL).....                                    | 1336 |
| 47.4.29        | Transmit Inter-Packet Gap (ENET_TIPG).....  | 1336 |
| 47.4.30        | Frame Truncation Length (ENET_FTRL).....  | 1337 |
| 47.4.31        | Transmit Accelerator Function Configuration (ENET_TACC).....                            | 1337 |
| 47.4.32        | Receive Accelerator Function Configuration (ENET_RACC).....                             | 1338 |
| 47.4.33        | Reserved Statistic Register (ENET_RMON_T_DROP).....                                     | 1339 |
| 47.4.34        | Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS).....                           | 1340 |
| 47.4.35        | Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT).....                       | 1340 |
| 47.4.36        | Tx Multicast Packets Statistic Register (ENET_RMON_T_MC_PKT).....                       | 1341 |
| 47.4.37        | Tx Packets with CRC/Align Error Statistic Register (ENET_RMON_T_CRC_ALIGN).....         | 1341 |
| 47.4.38        | Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET_RMON_T_UNDERSIZE)..... | 1342 |
| 47.4.39        | Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET_RMON_T_OVERSIZE).....  | 1342 |
| 47.4.40        | Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_T_FRAG).....    | 1343 |

| Section number | Title  | Page |
|----------------|--|------|
| 47.4.41        | Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET_RMON_T_JAB).....         | 1343 |
| 47.4.42        | Tx Collision Count Statistic Register (ENET_RMON_T_COL).....                                       | 1344 |
| 47.4.43        | Tx 64-Byte Packets Statistic Register (ENET_RMON_T_P64).....                                       | 1344 |
| 47.4.44        | Tx 65- to 127-byte Packets Statistic Register (ENET_RMON_T_P65TO127).....                          | 1345 |
| 47.4.45        | Tx 128- to 255-byte Packets Statistic Register (ENET_RMON_T_P128TO255).....                        | 1345 |
| 47.4.46        | Tx 256- to 511-byte Packets Statistic Register (ENET_RMON_T_P256TO511).....                        | 1346 |
| 47.4.47        | Tx 512- to 1023-byte Packets Statistic Register (ENET_RMON_T_P512TO1023).....                      | 1346 |
| 47.4.48        | Tx 1024- to 2047-byte Packets Statistic Register (ENET_RMON_T_P1024TO2047).....                    | 1347 |
| 47.4.49        | Tx Packets Greater Than 2048 Bytes Statistic Register (ENET_RMON_T_P_GTE2048).....                 | 1347 |
| 47.4.50        | Tx Octets Statistic Register (ENET_RMON_T_OCTETS).....   | 1348 |
| 47.4.51        | IEEE_T_DROP Reserved Statistic Register (ENET_IEEE_T_DROP).....                                    | 1348 |
| 47.4.52        | Frames Transmitted OK Statistic Register (ENET_IEEE_T_FRAME_OK).....                               | 1348 |
| 47.4.53        | Frames Transmitted with Single Collision Statistic Register (ENET_IEEE_T_ICOL).....                | 1349 |
| 47.4.54        | Frames Transmitted with Multiple Collisions Statistic Register (ENET_IEEE_T_MCOL).....             | 1349 |
| 47.4.55        | Frames Transmitted after Deferral Delay Statistic Register (ENET_IEEE_T_DEF).....                  | 1350 |
| 47.4.56        | Frames Transmitted with Late Collision Statistic Register (ENET_IEEE_T_LCOL).....                  | 1350 |
| 47.4.57        | Frames Transmitted with Excessive Collisions Statistic Register (ENET_IEEE_T_EXCOL).....           | 1351 |
| 47.4.58        | Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET_IEEE_T_MACERR).....              | 1351 |
| 47.4.59        | Frames Transmitted with Carrier Sense Error Statistic Register (ENET_IEEE_T_CSERR).....            | 1352 |
| 47.4.60        | ENET_IEEE_T_SQE.....   | 1352 |
| 47.4.61        | Flow Control Pause Frames Transmitted Statistic Register (ENET_IEEE_T_FDXFC).....                  | 1353 |
| 47.4.62        | Octet Count for Frames Transmitted w/o Error Statistic Register (ENET_IEEE_T_OCTETS_OK).....       | 1353 |
| 47.4.63        | Rx Packet Count Statistic Register (ENET_RMON_R_PACKETS).....                                      | 1354 |
| 47.4.64        | Rx Broadcast Packets Statistic Register (ENET_RMON_R_BC_PKT).....                                  | 1354 |
| 47.4.65        | Rx Multicast Packets Statistic Register (ENET_RMON_R_MC_PKT).....                                  | 1355 |
| 47.4.66        | Rx Packets with CRC/Align Error Statistic Register (ENET_RMON_R_CRC_ALIGN).....                    | 1355 |
| 47.4.67        | Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register<br>(ENET_RMON_R_UNDERSIZE)..... | 1356 |
| 47.4.68        | Rx Packets Greater Than MAX_FL and Good CRC Statistic Register (ENET_RMON_R_OVERSIZE).....         | 1356 |

| Section number | Title   | Page |
|----------------|---|------|
| 47.4.69        | Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_R_FRAG).....          | 1357 |
| 47.4.70        | Rx Packets Greater Than MAX_FL Bytes and Bad CRC Statistic Register (ENET_RMON_R_JAB).....    | 1357 |
| 47.4.71        | Reserved Statistic Register (ENET_RMON_R_RESVD_0).....  | 1357 |
| 47.4.72        | Rx 64-Byte Packets Statistic Register (ENET_RMON_R_P64).....                                  | 1358 |
| 47.4.73        | Rx 65- to 127-Byte Packets Statistic Register (ENET_RMON_R_P65TO127).....                     | 1358 |
| 47.4.74        | Rx 128- to 255-Byte Packets Statistic Register (ENET_RMON_R_P128TO255).....                   | 1359 |
| 47.4.75        | Rx 256- to 511-Byte Packets Statistic Register (ENET_RMON_R_P256TO511).....                   | 1359 |
| 47.4.76        | Rx 512- to 1023-Byte Packets Statistic Register (ENET_RMON_R_P512TO1023).....                 | 1360 |
| 47.4.77        | Rx 1024- to 2047-Byte Packets Statistic Register (ENET_RMON_R_P1024TO2047).....               | 1360 |
| 47.4.78        | Rx Packets Greater than 2048 Bytes Statistic Register (ENET_RMON_R_P_GTE2048).....            | 1361 |
| 47.4.79        | Rx Octets Statistic Register (ENET_RMON_R_OCTETS).....  | 1361 |
| 47.4.80        | Frames not Counted Correctly Statistic Register (ENET_IEEE_R_DROP).....                       | 1362 |
| 47.4.81        | Frames Received OK Statistic Register (ENET_IEEE_R_FRAME_OK).....                             | 1362 |
| 47.4.82        | Frames Received with CRC Error Statistic Register (ENET_IEEE_R_CRC).....                      | 1363 |
| 47.4.83        | Frames Received with Alignment Error Statistic Register (ENET_IEEE_R_ALIGN).....              | 1363 |
| 47.4.84        | Receive FIFO Overflow Count Statistic Register (ENET_IEEE_R_MACERR).....                      | 1364 |
| 47.4.85        | Flow Control Pause Frames Received Statistic Register (ENET_IEEE_R_FDXFC).....                | 1364 |
| 47.4.86        | Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)..... | 1365 |
| 47.4.87        | Adjustable Timer Control Register (ENET_ATCR).....  | 1365 |
| 47.4.88        | Timer Value Register (ENET_ATVR).....   | 1367 |
| 47.4.89        | Timer Offset Register (ENET_ATOFF).....   | 1367 |
| 47.4.90        | Timer Period Register (ENET_ATPER).....   | 1368 |
| 47.4.91        | Timer Correction Register (ENET_ATCOR).....   | 1368 |
| 47.4.92        | Time-Stamping Clock Period Register (ENET_ATINC).....   | 1369 |
| 47.4.93        | Timestamp of Last Transmitted Frame (ENET_ATSTMP).....  | 1369 |
| 47.4.94        | Timer Global Status Register (ENET_TGSR).....   | 1370 |
| 47.4.95        | Timer Control Status Register (ENET_TCSR <sub>n</sub> ).....                                  | 1371 |
| 47.4.96        | Timer Compare Capture Register (ENET_TCCR <sub>n</sub> ).....                                 | 1372 |

| 47.5.6         | Full-duplex flow control operation..... | 1393 |
| 47.5.7         | Magic packet detection.....             | 1394 |
| 47.5.8         | IP accelerator functions.....           | 1395 |
| 47.5.9         | Resets and stop controls.....           | 1400 |
| 47.5.10        | IEEE 1588 functions.....                | 1403 |
| 47.5.11        | FIFO thresholds.....                    | 1407 |
| 47.5.12        | Loopback options.....                   | 1410 |
| 47.5.13        | Legacy buffer descriptors.....          | 1411 |
| 47.5.14        | Enhanced buffer descriptors.....        | 1412 |
| 47.5.15        | Client FIFO application interface.....  | 1418 |
| 47.5.16        | FIFO protection.....                    | 1421 |
| 47.5.17        | Reference clock.....                    | 1424 |
| 47.5.18        | PHY management interface.....           | 1424 |
| 47.5.19        | Ethernet interfaces.....                | 1427 |

**Chapter 48**  
**Universal Serial Bus Full Speed OTG Controller (USBFSOTG)**

|        |   |      |
|--------|---|------|
| 48.1   | Introduction.....                                     | 1433 |
| 48.1.1 | USB.....  | 1433 |
| 48.1.2 | USB On-The-Go.....                                    | 1434 |
| 48.1.3 | USBFS Features.....                                   | 1435 |
| 48.2   | Functional description.....                           | 1435 |
| 48.2.1 | Data Structures.....                                  | 1436 |
| 48.2.2 | On-chip transceiver required external components..... | 1436 |

| Section number | Title  | Page |
|----------------|--|------|
| 48.3           | Programmers interface.....   | 1438 |
| 48.3.1         | Buffer Descriptor Table.....   | 1438 |
| 48.3.2         | RX vs. TX as a USB target device or USB host.....                    | 1439 |
| 48.3.3         | Addressing BDT entries.....  | 1440 |
| 48.3.4         | Buffer Descriptors (BDs).....  | 1441 |
| 48.3.5         | USB transaction.....   | 1443 |
| 48.4           | Memory map/Register definitions.....                                 | 1445 |
| 48.4.1         | Peripheral ID register (USB <sub>x</sub> _PERID).....                | 1447 |
| 48.4.2         | Peripheral ID Complement register (USB <sub>x</sub> _IDCOMP).....    | 1448 |
| 48.4.3         | Peripheral Revision register (USB <sub>x</sub> _REV).....            | 1448 |
| 48.4.4         | Peripheral Additional Info register (USB <sub>x</sub> _ADDINFO)..... | 1449 |
| 48.4.5         | OTG Interrupt Status register (USB <sub>x</sub> _OTGISTAT).....      | 1449 |
| 48.4.6         | OTG Interrupt Control register (USB <sub>x</sub> _OTGICR).....       | 1450 |
| 48.4.7         | OTG Status register (USB <sub>x</sub> _OTGSTAT).....                 | 1451 |
| 48.4.8         | OTG Control register (USB <sub>x</sub> _OTGCTL).....                 | 1452 |
| 48.4.9         | Interrupt Status register (USB <sub>x</sub> _ISTAT).....             | 1453 |
| 48.4.10        | Interrupt Enable register (USB <sub>x</sub> _INTEN).....             | 1454 |
| 48.4.11        | Error Interrupt Status register (USB <sub>x</sub> _ERRSTAT).....     | 1455 |
| 48.4.12        | Error Interrupt Enable register (USB <sub>x</sub> _ERREN).....       | 1456 |
| 48.4.13        | Status register (USB <sub>x</sub> _STAT).....                        | 1458 |
| 48.4.14        | Control register (USB <sub>x</sub> _CTL).....                        | 1459 |
| 48.4.15        | Address register (USB <sub>x</sub> _ADDR).....                       | 1460 |
| 48.4.16        | BDT Page register 1 (USB <sub>x</sub> _BDTPAGE1).....                | 1461 |
| 48.4.17        | Frame Number register Low (USB <sub>x</sub> _FRMNUML).....           | 1461 |
| 48.4.18        | Frame Number register High (USB <sub>x</sub> _FRMNUMH).....          | 1462 |
| 48.4.19        | Token register (USB <sub>x</sub> _TOKEN).....                        | 1462 |
| 48.4.20        | SOF Threshold register (USB <sub>x</sub> _SOFTHLD).....              | 1463 |
| 48.4.21        | BDT Page Register 2 (USB <sub>x</sub> _BDTPAGE2).....                | 1464 |
| 48.4.22        | BDT Page Register 3 (USB <sub>x</sub> _BDTPAGE3).....                | 1464 |

| Section number | Title  | Page |
|----------------|--|------|
| 48.4.23        | Endpoint Control register (USB <sub>x</sub> _ENDPT <sub>n</sub> )..... | 1465 |
| 48.4.24        | USB Control register (USB <sub>x</sub> _USBCTRL).....                  | 1466 |
| 48.4.25        | USB OTG Observe register (USB <sub>x</sub> _OBSERVE).....              | 1467 |
| 48.4.26        | USB OTG Control register (USB <sub>x</sub> _CONTROL).....              | 1467 |
| 48.4.27        | USB Transceiver Control register 0 (USB <sub>x</sub> _USBTRC0).....    | 1468 |
| 48.4.28        | Frame Adjust Register (USB <sub>x</sub> _USBFRMADJUST).....            | 1469 |
| 48.5           | OTG and Host mode operation.....                                       | 1469 |
| 48.6           | Host Mode Operation Examples.....                                      | 1470 |
| 48.7           | On-The-Go operation.....   | 1473 |
| 48.7.1         | OTG dual role A device operation.....                                  | 1473 |
| 48.7.2         | OTG dual role B device operation.....                                  | 1475 |

## Chapter 49

### USB Device Charger Detection Module (USBDCD)

|        |  |      |
|--------|--|------|
| 49.1   | Preface.....                           | 1477 |
| 49.1.1 | References.....                        | 1477 |
| 49.1.2 | Acronyms and abbreviations.....        | 1477 |
| 49.1.3 | Glossary.....                          | 1478 |
| 49.2   | Introduction.....                      | 1478 |
| 49.2.1 | Block diagram.....                     | 1478 |
| 49.2.2 | Features.....                          | 1479 |
| 49.2.3 | Modes of operation.....                | 1479 |
| 49.3   | Module signal descriptions.....        | 1480 |
| 49.4   | Memory map/Register definition.....    | 1481 |
| 49.4.1 | Control register (USBDCD_CONTROL)..... | 1482 |
| 49.4.2 | Clock register (USBDCD_CLOCK).....     | 1483 |
| 49.4.3 | Status register (USBDCD_STATUS).....   | 1485 |
| 49.4.4 | TIMER0 register (USBDCD_TIMER0).....   | 1486 |
| 49.4.5 | TIMER1 register (USBDCD_TIMER1).....   | 1487 |
| 49.4.6 | TIMER2 register (USBDCD_TIMER2).....   | 1488 |

| Section number | Title                               | Page |
|----------------|-------------------------------------|------|
| 49.5           | Functional description.....         | 1489 |
| 49.5.1         | The charger detection sequence..... | 1490 |
| 49.5.2         | Interrupts and events.....          | 1499 |
| 49.5.3         | Resets.....                         | 1501 |
| 49.6           | Initialization information.....     | 1502 |
| 49.7           | Application information.....        | 1502 |
| 49.7.1         | External pullups.....               | 1502 |
| 49.7.2         | Dead or weak battery.....           | 1502 |
| 49.7.3         | Handling unplug events.....         | 1503 |

## Chapter 50 USB Voltage Regulator (VREG)

|        |   |      |
|--------|---|------|
| 50.1   | Introduction.....                                     | 1505 |
| 50.1.1 | Overview.....   | 1505 |
| 50.1.2 | Features.....   | 1506 |
| 50.1.3 | Modes of Operation.....                               | 1507 |
| 50.2   | USB Voltage Regulator Module Signal Descriptions..... | 1507 |

## Chapter 51 USB High Speed OTG Controller (USBHS)

|        |   |      |
|--------|---|------|
| 51.1   | Introduction.....   | 1509 |
| 51.1.1 | Overview.....   | 1509 |
| 51.1.2 | Features.....   | 1510 |
| 51.1.3 | Modes of Operation.....   | 1511 |
| 51.2   | External Signal Description.....                                  | 1511 |
| 51.3   | Memory Map/Register Definition.....                               | 1512 |
| 51.3.1 | Identification Register (USBHS_ID).....                           | 1516 |
| 51.3.2 | General Hardware Parameters Register (USBHS_HWGENERAL).....       | 1517 |
| 51.3.3 | Host Hardware Parameters Register (USBHS_HWHOST).....             | 1518 |
| 51.3.4 | Device Hardware Parameters Register (USBHS_HWDEVICE).....         | 1519 |
| 51.3.5 | Transmit Buffer Hardware Parameters Register (USBHS_HWTXBUF)..... | 1520 |

| Section number | Title   | Page |
|----------------|---|------|
| 51.3.6         | Receive Buffer Hardware Parameters Register (USBHS_HWRXBUF).....                                | 1521 |
| 51.3.7         | General Purpose Timer n Load Register (USBHS_GPTIMERnLD).....                                   | 1521 |
| 51.3.8         | General Purpose Timer n Control Register (USBHS_GPTIMERnCTL).....                               | 1522 |
| 51.3.9         | System Bus Interface Configuration Register (USBHS_USB_SBUSCFG).....                            | 1523 |
| 51.3.10        | Host Controller Interface Version and Capability Registers Length Register (USBHS_HCVERSION) .. | 1525 |
| 51.3.11        | Host Controller Structural Parameters Register (USBHS_HCSPARAMS).....                           | 1526 |
| 51.3.12        | Host Controller Capability Parameters Register (USBHS_HCCPARAMS).....                           | 1527 |
| 51.3.13        | Device Controller Interface Version (USBHS_DCVERSION).....                                      | 1528 |
| 51.3.14        | Device Controller Capability Parameters (USBHS_DCCPARAMS).....                                  | 1529 |
| 51.3.15        | USB Command Register (USBHS_USBCMD).....  | 1530 |
| 51.3.16        | USB Status Register (USBHS_USBSTS).....   | 1533 |
| 51.3.17        | USB Interrupt Enable Register (USBHS_USBINTR).....  | 1537 |
| 51.3.18        | Frame Index Register (USBHS_FRINDEX).....   | 1540 |
| 51.3.19        | Periodic Frame List Base Address Register (USBHS_PERIODICLISTBASE).....                         | 1541 |
| 51.3.20        | Device Address Register (USBHS_DEVICEADDR).....   | 1542 |
| 51.3.21        | Current Asynchronous List Address Register (USBHS_ASYNCLISTADDR).....                           | 1543 |
| 51.3.22        | Endpoint List Address Register (USBHS_EPLISTADDR).....  | 1544 |
| 51.3.23        | Host TT Asynchronous Buffer Control (USBHS_TTCTRL).....   | 1544 |
| 51.3.24        | Master Interface Data Burst Size Register (USBHS_BURSTSIZE).....                                | 1545 |
| 51.3.25        | Transmit FIFO Tuning Control Register (USBHS_TXFILLTUNING).....                                 | 1546 |
| 51.3.26        | ULPI Register Access (USBHS_ULPI_VIEWPORT).....   | 1548 |
| 51.3.27        | Endpoint NAK Register (USBHS_ENDPTNAK).....   | 1550 |
| 51.3.28        | Endpoint NAK Enable Register (USBHS_ENDPTNAKEN).....  | 1551 |
| 51.3.29        | Configure Flag Register (USBHS_CONFIGFLAG).....   | 1552 |
| 51.3.30        | Port Status and Control Registers (USBHS_PORTSC1).....  | 1552 |
| 51.3.31        | On-the-Go Status and Control Register (USBHS_OTGSC).....  | 1558 |
| 51.3.32        | USB Mode Register (USBHS_USBMODE).....  | 1562 |
| 51.3.33        | Endpoint Setup Status Register (USBHS_EPSETUPSR).....   | 1564 |
| 51.3.34        | Endpoint Initialization Register (USBHS_EPPRIME).....   | 1565 |

| Section number | Title  | Page |
|----------------|--|------|
| 51.3.35        | Endpoint Flush Register (USBHS_EPFLUSH).....         | 1566 |
| 51.3.36        | Endpoint Status Register (USBHS_EPSR).....           | 1566 |
| 51.3.37        | Endpoint Complete Register (USBHS_EPCOMPLETE).....   | 1567 |
| 51.3.38        | Endpoint Control Register 0 (USBHS_EPCR0).....       | 1568 |
| 51.3.39        | Endpoint Control Register n (USBHS_EPCRn).....       | 1570 |
| 51.3.40        | USB General Control Register (USBHS_USBGENCTRL)..... | 1572 |
| 51.4           | Functional Description.....                          | 1573 |
| 51.4.1         | System Interface.....                                | 1573 |
| 51.4.2         | DMA Engine.....                                      | 1573 |
| 51.4.3         | FIFO RAM Controller.....                             | 1574 |
| 51.5           | Initialization/Application Information.....          | 1574 |
| 51.5.1         | Host Operation.....                                  | 1574 |
| 51.5.2         | Device Data Structures.....                          | 1574 |
| 51.5.3         | Device Operation.....                                | 1581 |
| 51.5.4         | Servicing Interrupts.....                            | 1602 |
| 51.5.5         | Deviations from the EHCI Specifications.....         | 1604 |

## Chapter 52 CAN (FlexCAN)

|        |   |      |
|--------|---|------|
| 52.1   | Introduction.....                             | 1613 |
| 52.1.1 | Overview.....                                 | 1614 |
| 52.1.2 | FlexCAN module features.....                  | 1615 |
| 52.1.3 | Modes of operation.....                       | 1616 |
| 52.2   | FlexCAN signal descriptions.....              | 1618 |
| 52.2.1 | CAN Rx .....                                  | 1618 |
| 52.2.2 | CAN Tx .....                                  | 1618 |
| 52.3   | Memory map/register definition.....           | 1618 |
| 52.3.1 | FlexCAN memory mapping.....                   | 1618 |
| 52.3.2 | Module Configuration Register (CANx_MCR)..... | 1623 |
| 52.3.3 | Control 1 register (CANx_CTRL1).....          | 1628 |

| Section number | Title  | Page |
|----------------|--|------|
| 52.3.4         | Free Running Timer (CANx_TIMER).....                         | 1631 |
| 52.3.5         | Rx Mailboxes Global Mask Register (CANx_RXMGMASK).....       | 1632 |
| 52.3.6         | Rx 14 Mask register (CANx_RX14MASK).....                     | 1633 |
| 52.3.7         | Rx 15 Mask register (CANx_RX15MASK).....                     | 1634 |
| 52.3.8         | Error Counter (CANx_ECR).....                                | 1634 |
| 52.3.9         | Error and Status 1 register (CANx_ESR1).....                 | 1636 |
| 52.3.10        | Interrupt Masks 1 register (CANx_IMASK1).....                | 1640 |
| 52.3.11        | Interrupt Flags 1 register (CANx_IFLAG1).....                | 1640 |
| 52.3.12        | Control 2 register (CANx_CTRL2).....                         | 1643 |
| 52.3.13        | Error and Status 2 register (CANx_ESR2).....                 | 1646 |
| 52.3.14        | CRC Register (CANx_CRCR).....                                | 1648 |
| 52.3.15        | Rx FIFO Global Mask register (CANx_RXFGMASK).....            | 1648 |
| 52.3.16        | Rx FIFO Information Register (CANx_RXFIR).....               | 1649 |
| 52.3.17        | Rx Individual Mask Registers (CANx_RXIMR <sub>n</sub> )..... | 1650 |
| 52.3.50        | Message buffer structure.....                                | 1651 |
| 52.3.51        | Rx FIFO structure.....                                       | 1657 |
| 52.4           | Functional description.....                                  | 1659 |
| 52.4.1         | Transmit process.....  | 1660 |
| 52.4.2         | Arbitration process.....                                     | 1660 |
| 52.4.3         | Receive process.....   | 1664 |
| 52.4.4         | Matching process.....  | 1666 |
| 52.4.5         | Move process.....  | 1671 |
| 52.4.6         | Data coherence.....  | 1672 |
| 52.4.7         | Rx FIFO.....   | 1676 |
| 52.4.8         | CAN protocol related features.....                           | 1677 |
| 52.4.9         | Clock domains and restrictions.....                          | 1684 |
| 52.4.10        | Modes of operation details.....                              | 1685 |
| 52.4.11        | Interrupts.....  | 1688 |
| 52.4.12        | Bus interface.....   | 1689 |

| Section number | Title                                       | Page |
|----------------|---|------|
| 52.5           | Initialization/application information..... | 1690 |
| 52.5.1         | FlexCAN initialization sequence.....        | 1690 |

## Chapter 53 Serial Peripheral Interface (SPI)

|         |   |      |
|---------|---|------|
| 53.1    | Introduction.....   | 1693 |
| 53.1.1  | Block Diagram.....  | 1693 |
| 53.1.2  | Features.....   | 1694 |
| 53.1.3  | Interface configurations.....   | 1696 |
| 53.1.4  | Modes of Operation.....   | 1696 |
| 53.2    | Module signal descriptions.....   | 1698 |
| 53.2.1  | PCS0/SS—Peripheral Chip Select/Slave Select.....  | 1698 |
| 53.2.2  | PCS1–PCS3—Peripheral Chip Selects 1–3.....  | 1699 |
| 53.2.3  | PCS4—Peripheral Chip Select 4.....  | 1699 |
| 53.2.4  | PCS5/PCSS—Peripheral Chip Select 5/Peripheral Chip Select Strobe.....                       | 1699 |
| 53.2.5  | SCK—Serial Clock.....   | 1699 |
| 53.2.6  | SIN—Serial Input.....   | 1699 |
| 53.2.7  | SOUT—Serial Output.....   | 1700 |
| 53.3    | Memory Map/Register Definition.....   | 1700 |
| 53.3.1  | Module Configuration Register (SPLx_MCR).....   | 1703 |
| 53.3.2  | Transfer Count Register (SPLx_TCR).....   | 1706 |
| 53.3.3  | Clock and Transfer Attributes Register (In Master Mode) (SPLx_CTAR <sub>n</sub> ).....      | 1706 |
| 53.3.4  | Clock and Transfer Attributes Register (In Slave Mode) (SPLx_CTAR <sub>n</sub> _SLAVE)..... | 1711 |
| 53.3.5  | Status Register (SPLx_SR).....  | 1713 |
| 53.3.6  | DMA/Interrupt Request Select and Enable Register (SPLx_RSER).....                           | 1716 |
| 53.3.7  | PUSH TX FIFO Register In Master Mode (SPLx_PUSHR).....                                      | 1718 |
| 53.3.8  | PUSH TX FIFO Register In Slave Mode (SPLx_PUSHR_SLAVE).....                                 | 1720 |
| 53.3.9  | POP RX FIFO Register (SPLx_POPR).....   | 1720 |
| 53.3.10 | Transmit FIFO Registers (SPLx_TXFR <sub>n</sub> ).....                                      | 1721 |
| 53.3.11 | Receive FIFO Registers (SPLx_RXFR <sub>n</sub> ).....                                       | 1721 |

| Section number | Title  | Page |
|----------------|--|------|
| 53.4           | Functional description.....                          | 1722 |
| 53.4.1         | Start and Stop of module transfers.....              | 1723 |
| 53.4.2         | Serial Peripheral Interface (SPI) configuration..... | 1723 |
| 53.4.3         | Module baud rate and clock delay generation.....     | 1727 |
| 53.4.4         | Transfer formats.....                                | 1731 |
| 53.4.5         | Continuous Serial Communications Clock.....          | 1740 |
| 53.4.6         | Slave Mode Operation Constraints.....                | 1742 |
| 53.4.7         | Interrupts/DMA requests.....                         | 1742 |
| 53.4.8         | Power saving features.....                           | 1744 |
| 53.5           | Initialization/application information.....          | 1745 |
| 53.5.1         | How to manage queues.....                            | 1746 |
| 53.5.2         | Switching Master and Slave mode.....                 | 1746 |
| 53.5.3         | Initializing Module in Master/Slave Modes.....       | 1747 |
| 53.5.4         | Baud rate settings.....                              | 1747 |
| 53.5.5         | Delay settings.....                                  | 1748 |
| 53.5.6         | Calculation of FIFO pointer addresses.....           | 1748 |

## Chapter 54 Inter-Integrated Circuit (I2C)

|        |  |      |
|--------|--|------|
| 54.1   | Introduction.....                            | 1751 |
| 54.1.1 | Features.....                                | 1751 |
| 54.1.2 | Modes of operation.....                      | 1752 |
| 54.1.3 | Block diagram.....                           | 1752 |
| 54.2   | I2C signal descriptions.....                 | 1753 |
| 54.3   | Memory map/register definition.....          | 1754 |
| 54.3.1 | I2C Address Register 1 (I2Cx_A1).....        | 1755 |
| 54.3.2 | I2C Frequency Divider register (I2Cx_F)..... | 1755 |
| 54.3.3 | I2C Control Register 1 (I2Cx_C1).....        | 1756 |
| 54.3.4 | I2C Status register (I2Cx_S).....            | 1758 |
| 54.3.5 | I2C Data I/O register (I2Cx_D).....          | 1760 |

| Section number | Title   | Page |
|----------------|---|------|
| 54.3.6         | I2C Control Register 2 (I2Cx_C2).....                         | 1760 |
| 54.3.7         | I2C Programmable Input Glitch Filter Register (I2Cx_FLT)..... | 1761 |
| 54.3.8         | I2C Range Address register (I2Cx_RA).....                     | 1762 |
| 54.3.9         | I2C SMBus Control and Status register (I2Cx_SMB).....         | 1762 |
| 54.3.10        | I2C Address Register 2 (I2Cx_A2).....                         | 1764 |
| 54.3.11        | I2C SCL Low Timeout Register High (I2Cx_SLTH).....            | 1764 |
| 54.3.12        | I2C SCL Low Timeout Register Low (I2Cx_SLTL).....             | 1765 |
| 54.4           | Functional description.....                                   | 1765 |
| 54.4.1         | I2C protocol.....   | 1765 |
| 54.4.2         | 10-bit address.....   | 1770 |
| 54.4.3         | Address matching.....   | 1772 |
| 54.4.4         | System management bus specification.....                      | 1773 |
| 54.4.5         | Resets.....   | 1775 |
| 54.4.6         | Interrupts.....   | 1775 |
| 54.4.7         | Programmable input glitch filter.....                         | 1778 |
| 54.4.8         | Address matching wake-up.....                                 | 1778 |
| 54.4.9         | DMA support.....  | 1779 |
| 54.5           | Initialization/application information.....                   | 1779 |

## Chapter 55 Universal Asynchronous Receiver/Transmitter (UART)

|        |   |      |
|--------|---|------|
| 55.1   | Introduction.....                               | 1783 |
| 55.1.1 | Features.....                                   | 1783 |
| 55.1.2 | Modes of operation.....                         | 1785 |
| 55.2   | UART signal descriptions.....                   | 1786 |
| 55.2.1 | Detailed signal descriptions.....               | 1787 |
| 55.3   | Memory map and registers.....                   | 1788 |
| 55.3.1 | UART Baud Rate Registers: High (UARTx_BDH)..... | 1800 |
| 55.3.2 | UART Baud Rate Registers: Low (UARTx_BDL).....  | 1801 |
| 55.3.3 | UART Control Register 1 (UARTx_C1).....         | 1802 |

| Section number | Title   | Page |
|----------------|---|------|
| 55.3.4         | UART Control Register 2 (UARTx_C2).....                 | 1803 |
| 55.3.5         | UART Status Register 1 (UARTx_S1).....                  | 1805 |
| 55.3.6         | UART Status Register 2 (UARTx_S2).....                  | 1808 |
| 55.3.7         | UART Control Register 3 (UARTx_C3).....                 | 1810 |
| 55.3.8         | UART Data Register (UARTx_D).....                       | 1811 |
| 55.3.9         | UART Match Address Registers 1 (UARTx_MA1).....         | 1812 |
| 55.3.10        | UART Match Address Registers 2 (UARTx_MA2).....         | 1813 |
| 55.3.11        | UART Control Register 4 (UARTx_C4).....                 | 1813 |
| 55.3.12        | UART Control Register 5 (UARTx_C5).....                 | 1814 |
| 55.3.13        | UART Extended Data Register (UARTx_ED).....             | 1815 |
| 55.3.14        | UART Modem Register (UARTx_MODEM).....                  | 1816 |
| 55.3.15        | UART Infrared Register (UARTx_IR).....                  | 1817 |
| 55.3.16        | UART FIFO Parameters (UARTx_PFIFO).....                 | 1818 |
| 55.3.17        | UART FIFO Control Register (UARTx_CFIFO).....           | 1819 |
| 55.3.18        | UART FIFO Status Register (UARTx_SFIFO).....            | 1820 |
| 55.3.19        | UART FIFO Transmit Watermark (UARTx_TWFIFO).....        | 1821 |
| 55.3.20        | UART FIFO Transmit Count (UARTx_TCFIFO).....            | 1822 |
| 55.3.21        | UART FIFO Receive Watermark (UARTx_RWFIFO).....         | 1822 |
| 55.3.22        | UART FIFO Receive Count (UARTx_RCFIFO).....             | 1823 |
| 55.3.23        | UART 7816 Control Register (UARTx_C7816).....           | 1823 |
| 55.3.24        | UART 7816 Interrupt Enable Register (UARTx_IE7816)..... | 1825 |
| 55.3.25        | UART 7816 Interrupt Status Register (UARTx_IS7816)..... | 1826 |
| 55.3.26        | UART 7816 Wait Parameter Register (UARTx_WP7816T0)..... | 1827 |
| 55.3.27        | UART 7816 Wait Parameter Register (UARTx_WP7816T1)..... | 1828 |
| 55.3.28        | UART 7816 Wait N Register (UARTx_WN7816).....           | 1828 |
| 55.3.29        | UART 7816 Wait FD Register (UARTx_WF7816).....          | 1829 |
| 55.3.30        | UART 7816 Error Threshold Register (UARTx_ET7816).....  | 1829 |
| 55.3.31        | UART 7816 Transmit Length Register (UARTx_TL7816).....  | 1830 |
| 55.3.32        | UART CEA709.1-B Control Register 6 (UARTx_C6).....      | 1831 |

| Section number | Title  | Page |
|----------------|--|------|
| 55.3.33        | UART CEA709.1-B Packet Cycle Time Counter High (UARTx_PCTH)..... | 1831 |
| 55.3.34        | UART CEA709.1-B Packet Cycle Time Counter Low (UARTx_PCTL).....  | 1832 |
| 55.3.35        | UART CEA709.1-B Beta1 Timer (UARTx_BIT).....                     | 1832 |
| 55.3.36        | UART CEA709.1-B Secondary Delay Timer High (UARTx_SDTH).....     | 1833 |
| 55.3.37        | UART CEA709.1-B Secondary Delay Timer Low (UARTx_SDTL).....      | 1833 |
| 55.3.38        | UART CEA709.1-B Preamble (UARTx_PRE).....                        | 1833 |
| 55.3.39        | UART CEA709.1-B Transmit Packet Length (UARTx_TPL).....          | 1834 |
| 55.3.40        | UART CEA709.1-B Interrupt Enable Register (UARTx_IE).....        | 1834 |
| 55.3.41        | UART CEA709.1-B WBASE (UARTx_WB).....                            | 1835 |
| 55.3.42        | UART CEA709.1-B Status Register (UARTx_S3).....                  | 1836 |
| 55.3.43        | UART CEA709.1-B Status Register (UARTx_S4).....                  | 1837 |
| 55.3.44        | UART CEA709.1-B Received Packet Length (UARTx_RPL).....          | 1838 |
| 55.3.45        | UART CEA709.1-B Received Preamble Length (UARTx_RPREL).....      | 1839 |
| 55.3.46        | UART CEA709.1-B Collision Pulse Width (UARTx_CPW).....           | 1839 |
| 55.3.47        | UART CEA709.1-B Receive Indeterminate Time (UARTx_RIDT).....     | 1839 |
| 55.3.48        | UART CEA709.1-B Transmit Indeterminate Time (UARTx_TIDT).....    | 1840 |
| 55.4           | Functional description.....                                      | 1840 |
| 55.4.1         | CEA709.1-B.....  | 1840 |
| 55.4.2         | Transmitter.....   | 1851 |
| 55.4.3         | Receiver.....  | 1856 |
| 55.4.4         | Baud rate generation.....  | 1865 |
| 55.4.5         | Data format (non ISO-7816).....                                  | 1867 |
| 55.4.6         | Single-wire operation.....                                       | 1870 |
| 55.4.7         | Loop operation.....  | 1871 |
| 55.4.8         | ISO-7816/smartcard support.....                                  | 1871 |
| 55.4.9         | Infrared interface.....  | 1876 |
| 55.5           | Reset.....   | 1877 |

## Chapter 56 Secured digital host controller (SDHC)

|        |  |      |
|--------|--|------|
| 56.1   | Introduction.....                              | 1889 |
| 56.2   | Overview.....                                  | 1889 |
| 56.2.1 | Supported types of cards.....                  | 1889 |
| 56.2.2 | SDHC block diagram.....                        | 1890 |
| 56.2.3 | Features.....                                  | 1891 |
| 56.2.4 | Modes and operations.....                      | 1892 |
| 56.3   | SDHC signal descriptions.....                  | 1893 |
| 56.4   | Memory map and register definition.....        | 1894 |
| 56.4.1 | DMA System Address register (SDHC_DSADDR)..... | 1895 |
| 56.4.2 | Block Attributes register (SDHC_BLKATTR).....  | 1896 |
| 56.4.3 | Command Argument register (SDHC_CMDARG).....   | 1897 |
| 56.4.4 | Transfer Type register (SDHC_XFERTYP).....     | 1897 |
| 56.4.5 | Command Response 0 (SDHC_CMDRSP0).....         | 1902 |

| Section number | Title  | Page |
|----------------|--|------|
| 56.4.6         | Command Response 1 (SDHC_CMDRSP1).....                 | 1902 |
| 56.4.7         | Command Response 2 (SDHC_CMDRSP2).....                 | 1902 |
| 56.4.8         | Command Response 3 (SDHC_CMDRSP3).....                 | 1903 |
| 56.4.9         | Buffer Data Port register (SDHC_DATPORT).....          | 1904 |
| 56.4.10        | Present State register (SDHC_PRSSTAT).....             | 1904 |
| 56.4.11        | Protocol Control register (SDHC_PROCTL).....           | 1910 |
| 56.4.12        | System Control register (SDHC_SYSCTL).....             | 1914 |
| 56.4.13        | Interrupt Status register (SDHC_IRQSTAT).....          | 1917 |
| 56.4.14        | Interrupt Status Enable register (SDHC_IRQSTATEN)..... | 1922 |
| 56.4.15        | Interrupt Signal Enable register (SDHC_IRQSIGEN).....  | 1925 |
| 56.4.16        | Auto CMD12 Error Status Register (SDHC_AC12ERR).....   | 1927 |
| 56.4.17        | Host Controller Capabilities (SDHC_HTCAPBLT).....      | 1931 |
| 56.4.18        | Watermark Level Register (SDHC_WML).....               | 1933 |
| 56.4.19        | Force Event register (SDHC_FEVT).....                  | 1934 |
| 56.4.20        | ADMA Error Status register (SDHC_ADMAES).....          | 1936 |
| 56.4.21        | ADMA System Addressregister (SDHC_ADSADDR).....        | 1938 |
| 56.4.22        | Vendor Specific register (SDHC_VENDOR).....            | 1939 |
| 56.4.23        | MMC Boot register (SDHC_MMCBOOT).....                  | 1940 |
| 56.4.24        | Host Controller Version (SDHC_HOSTVER).....            | 1941 |
| 56.5           | Functional description.....                            | 1942 |
| 56.5.1         | Data buffer.....                                       | 1942 |
| 56.5.2         | DMA crossbar switch interface.....                     | 1948 |
| 56.5.3         | SD protocol unit.....                                  | 1954 |
| 56.5.4         | Clock and reset manager.....                           | 1956 |
| 56.5.5         | Clock generator.....                                   | 1957 |
| 56.5.6         | SDIO card interrupt.....                               | 1957 |
| 56.5.7         | Card insertion and removal detection.....              | 1959 |

| Section number | Title  | Page |
|----------------|--|------|
| 56.5.8         | Power management and wakeup events.....                | 1960 |
| 56.5.9         | MMC fast boot.....                                     | 1961 |
| 56.6           | Initialization/application of SDHC.....                | 1963 |
| 56.6.1         | Command send and response receive basic operation..... | 1963 |
| 56.6.2         | Card Identification mode.....                          | 1964 |
| 56.6.3         | Card access.....                                       | 1969 |
| 56.6.4         | Switch function.....                                   | 1980 |
| 56.6.5         | ADMA operation.....                                    | 1982 |
| 56.6.6         | Fast boot operation.....                               | 1983 |
| 56.6.7         | Commands for MMC/SD/SDIO/CE-ATA.....                   | 1987 |
| 56.7           | Software restrictions.....                             | 1993 |
| 56.7.1         | Initialization active.....                             | 1993 |
| 56.7.2         | Software polling procedure.....                        | 1993 |
| 56.7.3         | Suspend operation.....                                 | 1994 |
| 56.7.4         | Data length setting.....                               | 1994 |
| 56.7.5         | (A)DMA address setting.....                            | 1994 |
| 56.7.6         | Data port access.....                                  | 1994 |
| 56.7.7         | Change clock frequency.....                            | 1994 |
| 56.7.8         | Multi-block read.....                                  | 1995 |

## Chapter 57 Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

|        |  |      |
|--------|--|------|
| 57.1   | Introduction.....                                      | 1997 |
| 57.1.1 | Features.....  | 1997 |
| 57.1.2 | Block diagram.....                                     | 1998 |
| 57.1.3 | Modes of operation.....                                | 1998 |
| 57.2   | External signals.....                                  | 1999 |
| 57.3   | Memory map and register definition.....                | 2000 |
| 57.3.1 | SAI Transmit Control Register (I2Sx_TCSR).....         | 2003 |
| 57.3.2 | SAI Transmit Configuration 1 Register (I2Sx_TCR1)..... | 2006 |

| Section number | Title  | Page |
|----------------|--|------|
| 57.3.3         | SAI Transmit Configuration 2 Register (I2Sx_TCR2)..... | 2006 |
| 57.3.4         | SAI Transmit Configuration 3 Register (I2Sx_TCR3)..... | 2008 |
| 57.3.5         | SAI Transmit Configuration 4 Register (I2Sx_TCR4)..... | 2009 |
| 57.3.6         | SAI Transmit Configuration 5 Register (I2Sx_TCR5)..... | 2010 |
| 57.3.7         | SAI Transmit Data Register (I2Sx_TDRn).....            | 2011 |
| 57.3.8         | SAI Transmit FIFO Register (I2Sx_TFRn).....            | 2011 |
| 57.3.9         | SAI Transmit Mask Register (I2Sx_TMR).....             | 2012 |
| 57.3.10        | SAI Receive Control Register (I2Sx_RCSR).....          | 2013 |
| 57.3.11        | SAI Receive Configuration 1 Register (I2Sx_RCR1).....  | 2016 |
| 57.3.12        | SAI Receive Configuration 2 Register (I2Sx_RCR2).....  | 2016 |
| 57.3.13        | SAI Receive Configuration 3 Register (I2Sx_RCR3).....  | 2018 |
| 57.3.14        | SAI Receive Configuration 4 Register (I2Sx_RCR4).....  | 2019 |
| 57.3.15        | SAI Receive Configuration 5 Register (I2Sx_RCR5).....  | 2020 |
| 57.3.16        | SAI Receive Data Register (I2Sx_RDRn).....             | 2021 |
| 57.3.17        | SAI Receive FIFO Register (I2Sx_RFRn).....             | 2022 |
| 57.3.18        | SAI Receive Mask Register (I2Sx_RMR).....              | 2022 |
| 57.3.19        | SAI MCLK Control Register (I2Sx_MCR).....              | 2023 |
| 57.3.20        | SAI MCLK Divide Register (I2Sx_MDR).....               | 2024 |
| 57.4           | Functional description.....                            | 2025 |
| 57.4.1         | SAI clocking.....                                      | 2025 |
| 57.4.2         | SAI resets.....  | 2027 |
| 57.4.3         | Synchronous modes.....                                 | 2028 |
| 57.4.4         | Frame sync configuration.....                          | 2029 |
| 57.4.5         | Data FIFO.....   | 2029 |
| 57.4.6         | Word mask register.....                                | 2031 |

| Section number | Title                            | Page |
|----------------|----------------------------------|------|
| 57.4.7         | Interrupts and DMA requests..... | 2031 |

## Chapter 58 General-Purpose Input/Output (GPIO)

|        |  |      |
|--------|--|------|
| 58.1   | Introduction.....                              | 2035 |
| 58.1.1 | Features.....                                  | 2035 |
| 58.1.2 | Modes of operation.....                        | 2035 |
| 58.1.3 | GPIO signal descriptions.....                  | 2036 |
| 58.2   | Memory map and register definition.....        | 2037 |
| 58.2.1 | Port Data Output Register (GPIOx_PDOR).....    | 2039 |
| 58.2.2 | Port Set Output Register (GPIOx_PSOR).....     | 2040 |
| 58.2.3 | Port Clear Output Register (GPIOx_PCOR).....   | 2040 |
| 58.2.4 | Port Toggle Output Register (GPIOx_PTOR).....  | 2041 |
| 58.2.5 | Port Data Input Register (GPIOx_PDIR).....     | 2041 |
| 58.2.6 | Port Data Direction Register (GPIOx_PDDR)..... | 2042 |
| 58.3   | FGPIO memory map and register definition.....  | 2042 |
| 58.3.1 | Port Data Output Register (FGPIO_PDOR).....    | 2043 |
| 58.3.2 | Port Set Output Register (FGPIO_PSOR).....     | 2043 |
| 58.3.3 | Port Clear Output Register (FGPIO_PCOR).....   | 2044 |
| 58.3.4 | Port Toggle Output Register (FGPIO_PTOR).....  | 2044 |
| 58.3.5 | Port Data Input Register (FGPIO_PDIR).....     | 2045 |
| 58.3.6 | Port Data Direction Register (FGPIO_PDDR)..... | 2045 |
| 58.4   | Functional description.....                    | 2045 |
| 58.4.1 | General-purpose input.....                     | 2045 |
| 58.4.2 | General-purpose output.....                    | 2046 |
| 58.4.3 | IOPORT.....                                    | 2046 |

## Chapter 59 Touch sense input (TSI)

|      |                   |      |
|------|-------------------|------|
| 59.1 | Introduction..... | 2047 |
| 59.2 | Features.....     | 2047 |

| Section number | Title  | Page |
|----------------|--|------|
| 59.3           | Overview.....  | 2048 |
| 59.3.1         | Electrode capacitance measurement unit.....                | 2048 |
| 59.3.2         | Electrode scan unit.....                                   | 2049 |
| 59.3.3         | Touch detection unit.....                                  | 2050 |
| 59.4           | Modes of operation.....                                    | 2050 |
| 59.4.1         | TSI disabled mode.....                                     | 2051 |
| 59.4.2         | TSI active mode.....                                       | 2051 |
| 59.4.3         | TSI low-power mode.....                                    | 2051 |
| 59.4.4         | Block diagram.....   | 2052 |
| 59.5           | TSI signal descriptions.....                               | 2053 |
| 59.5.1         | TSI_IN[15:0].....  | 2053 |
| 59.6           | Memory map and register definition.....                    | 2053 |
| 59.6.1         | General Control and Status register (TSIx_GENCS).....      | 2054 |
| 59.6.2         | SCAN Control register (TSIx_SCANC).....                    | 2058 |
| 59.6.3         | Pin Enable register (TSIx_PEN).....                        | 2060 |
| 59.6.4         | Wake-Up Channel Counter Register (TSIx_WUCNTR).....        | 2062 |
| 59.6.5         | Counter Register (TSIx_CNTR <i>n</i> ).....                | 2062 |
| 59.6.6         | Low-Power Channel Threshold register (TSIx_THRESHOLD)..... | 2063 |
| 59.7           | Functional description.....                                | 2063 |
| 59.7.1         | Capacitance measurement.....                               | 2063 |
| 59.7.2         | TSI measurement result.....                                | 2067 |
| 59.7.3         | Electrode scan unit.....                                   | 2068 |

# Chapter 1

## About This Document

### 1.1 Overview

#### 1.1.1 Purpose

This document describes the features, architecture, and programming model of the Freescale K60K61 microcontroller.

#### 1.1.2 Audience

This document is intended for system architects and software application developers who are using (or considering using) the K60 microcontroller in a system.

### 1.2 Conventions

#### 1.2.1 Numbering systems

The following suffixes identify different numbering systems:

| This suffix | Identifies a  |
|-------------|---|
| b           | Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix <i>0b</i> .                |
| d           | Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.    |
| h           | Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix <i>0x</i> . |

## 1.2.2 Typographic notation

The following typographic notation is used throughout this document:

| Example               | Description  |
|-----------------------|--|
| <i>placeholder, x</i> | Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.  |
| <code>code</code>     | Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.   |
| SR[SCM]               | A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).  |
| REVNO[6:4], XAD[7:0]  | Numbers in brackets and separated by a colon represent either: <ul style="list-style-type: none"> <li>• A subset of a register's named field<br/>For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.</li> <li>• A continuous range of individual signals of a bus<br/>For example, XAD[7:0] refers to signals 7–0 of the XAD bus.</li> </ul> |

## 1.2.3 Special terms

The following terms have special meanings:

| Term       | Meaning  |
|------------|--|
| asserted   | Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>• An active-high signal is asserted when high (1).</li> <li>• An active-low signal is asserted when low (0).</li> </ul>   |
| deasserted | Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>• An active-high signal is deasserted when low (0).</li> <li>• An active-low signal is deasserted when high (1).</li> </ul> <p>In some cases, deasserted signals are described as <i>negated</i>.</p> |
| reserved   | Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.   |
| w1c        | Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."   |

# Chapter 2

## Introduction

### 2.1 Overview

This chapter provides high-level descriptions of the modules available on the devices covered by this document.

### 2.2 Module Functional Categories

The modules on this device are grouped into functional categories. The following sections describe the modules assigned to each category in more detail.

**Table 2-1. Module functional categories**

| Module category            | Description   |
|----------------------------|---|
| ARM® Cortex®-M4 based core | <ul style="list-style-type: none"> <li>• 32-bit MCU core from ARM's Cortex-M class adding DSP instructions and single-precision floating point unit based on ARMv7 architecture with 16 KB of cache in some devices</li> </ul>  |
| System                     | <ul style="list-style-type: none"> <li>• System integration module</li> <li>• Power management and mode controllers               <ul style="list-style-type: none"> <li>• Multiple power modes available based on run, wait, stop, and power-down modes</li> </ul> </li> <li>• Low-leakage wakeup unit</li> <li>• Miscellaneous control module</li> <li>• Crossbar switch</li> <li>• Memory protection unit</li> <li>• Peripheral bridge</li> <li>• Direct memory access (DMA) controller with multiplexer to increase available DMA requests.</li> <li>• External watchdog monitor</li> <li>• Watchdog</li> </ul> |

*Table continues on the next page...*

**Table 2-1. Module functional categories (continued)**

| Module category                | Description  |
|--------------------------------|--|
| Memories                       | <ul style="list-style-type: none"> <li>• Internal memories include:               <ul style="list-style-type: none"> <li>• Program flash memory</li> <li>• On devices with FlexMemory: FlexMemory                   <ul style="list-style-type: none"> <li>• FlexNVM</li> <li>• FlexRAM</li> </ul> </li> <li>• On devices with program flash only: Programming acceleration RAM</li> <li>• SRAM</li> <li>• Cache memory</li> </ul> </li> <li>• External memory or peripheral bus interface: FlexBus</li> <li>• Serial programming interface: EzPort</li> <li>• DDR memory controller</li> <li>• NAND flash controller</li> </ul> |
| Clocks                         | <ul style="list-style-type: none"> <li>• Multiple clock generation options available from internally- and externally-generated clocks</li> <li>• System oscillator to provide clock source for the MCU</li> <li>• RTC oscillator to provide clock source for the RTC</li> </ul>  |
| Security                       | <ul style="list-style-type: none"> <li>• Cyclic Redundancy Check module for error detection</li> <li>• Hardware encryption, along with a random number generator</li> <li>• Tamper detect and secure storage</li> </ul>  |
| Analog                         | <ul style="list-style-type: none"> <li>• High speed analog-to-digital converter with integrated programmable gain amplifier</li> <li>• Comparator</li> <li>• Digital-to-analog converter</li> <li>• Internal voltage reference</li> <li>• Bandgap voltage reference</li> </ul>   |
| Timers                         | <ul style="list-style-type: none"> <li>• Programmable delay block</li> <li>• FlexTimers</li> <li>• Periodic interrupt timer</li> <li>• Low power timer</li> <li>• Carrier modulator transmitter</li> <li>• Independent real time clock</li> </ul>  |
| Communications                 | <ul style="list-style-type: none"> <li>• Ethernet MAC with IEEE 1588 capability</li> <li>• USB OTG controller with built-in FS/LS transceiver</li> <li>• USB device charger detect</li> <li>• USB voltage regulator</li> <li>• HS USB OTG controller with ULPI interface</li> <li>• CAN</li> <li>• Serial peripheral interface</li> <li>• Inter-integrated circuit (I<sup>2</sup>C)</li> <li>• UART</li> <li>• Secured Digital host controller</li> <li>• Integrated interchip sound (I<sup>2</sup>S)</li> </ul>   |
| Human-Machine Interfaces (HMI) | <ul style="list-style-type: none"> <li>• General purpose input/output controller</li> <li>• Capacitive touch sense input interface enabled in hardware</li> </ul>  |

### 2.2.1 ARM® Cortex®-M4 based core modules

The following core modules are available on this device.

**Table 2-2. Core modules**

| Module                    | Description   |
|---------------------------|---|
| ARM Cortex-M4             | The ARM Cortex-M4 is the newest member of the Cortex M Series of processors targeting microcontroller cores focused on very cost sensitive, deterministic, interrupt driven environments. The Cortex M4 processor is based on the ARMv7 Architecture and Thumb®-2 ISA and is upward compatible with the Cortex M3, Cortex M1, and Cortex M0 architectures. Cortex M4 improvements include an ARMv7 Thumb-2 DSP (ported from the ARMv7-A/R profile architectures) providing 32-bit instructions with SIMD (single instruction multiple data) DSP style multiply-accumulates and saturating arithmetic.                   |
| Floating point unit (FPU) | A single-precision floating point unit (FPU) that is compliant to the <i>IEEE Standard for Floating-Point Arithmetic</i> (IEEE 754).  |
| NVIC                      | The ARMv7-M exception model and nested-vector interrupt controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels.<br><br>The NVIC replaces shadow registers with equivalent system and simplified programmability. The NVIC contains the address of the function to execute for a particular handler. The address is fetched via the instruction port allowing parallel register stacking and look-up. The first sixteen entries are allocated to ARM internal sources with the others mapping to MCU-defined interrupts. |
| AWIC                      | The primary function of the Asynchronous Wake-up Interrupt Controller (AWIC) is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.  |
| Debug interfaces          | Most of this device's debug is based on the ARM CoreSight™ architecture. Four debug interfaces are supported: <ul style="list-style-type: none"> <li>• IEEE 1149.1 JTAG</li> <li>• IEEE 1149.7 JTAG (cJTAG)</li> <li>• Serial Wire Debug (SWD)</li> <li>• ARM Real-Time Trace Interface</li> </ul>  |

## 2.2.2 System Modules

The following system modules are available on this device.

**Table 2-3. System modules**

| Module                            | Description  |
|-----------------------------------|--|
| System integration module (SIM)   | The SIM includes integration logic and several module configuration settings.  |
| System mode controller (SMC)      | The SMC provides control and protection on entry and exit to each power mode, control for the Power management controller (PMC), and reset entry and exit for the complete MCU.  |
| Power management controller (PMC) | The PMC provides the user with multiple power options. Ten different modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability and selectable LVD trip points. |
| Low-leakage wakeup unit (LLWU)    | The LLWU module allows the device to wake from low leakage power modes (LLS and VLLS) through various internal peripheral and external pin sources.  |

*Table continues on the next page...*

**Table 2-3. System modules (continued)**

| Module                                | Description   |
|---------------------------------------|---|
| Miscellaneous control module (MCM)    | The MCM includes integration logic and embedded trace buffer details.   |
| Crossbar switch (XBS)                 | The XBS connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.                                      |
| Memory protection unit (MPU)          | The MPU provides memory protection and task isolation. It concurrently monitors all bus master transactions for the slave connections.  |
| Peripheral bridges                    | The peripheral bridge converts the crossbar switch interface to an interface to access a majority of peripherals on the device.   |
| DMA multiplexer (DMAMUX)              | The DMA multiplexer selects from many DMA requests down to a smaller number for the DMA controller.   |
| Direct memory access (DMA) controller | The DMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.  |
| External watchdog monitor (EWM)       | The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.   |
| Software watchdog (WDOG)              | The WDOG monitors internal system operation and forces a reset in case of failure. It can run from an independent 1 KHz low power oscillator with a programmable refresh window to detect deviations in program flow or system frequency. |

### 2.2.3 Memories and Memory Interfaces

The following memories and memory interfaces are available on this device.

**Table 2-4. Memories and memory interfaces**

| Module                  | Description  |
|-------------------------|--|
| Flash memory            | <ul style="list-style-type: none"> <li>• Program flash memory — non-volatile flash memory that can execute program code</li> <li>• FlexMemory — encompasses the following memory types:               <ul style="list-style-type: none"> <li>• For devices with FlexNVM: FlexNVM — Non-volatile flash memory that can execute program code, store data, or backup EEPROM data</li> <li>• For devices with FlexNVM: FlexRAM — RAM memory that can be used as traditional RAM or as high-endurance EEPROM storage, and also accelerates flash programming</li> <li>• For devices with only program flash memory: Programming acceleration RAM — RAM memory that accelerates flash programming</li> </ul> </li> </ul> |
| Flash memory controller | Manages the interface between the device and the on-chip flash memory.   |
| SRAM                    | Internal system RAM. Partial SRAM kept powered in VLLS2 low leakage mode.  |
| Local memory controller | Manages simultaneous accesses to system RAM by multiple master peripherals and core. Controls cache which improves system performance by providing single-cycle access to the instruction and data pipelines.  |
| System register file    | 32-byte register file that is accessible during all power modes and is powered by VDD.   |

*Table continues on the next page...*

**Table 2-4. Memories and memory interfaces (continued)**

| Module  | Description   |
|---|---|
| <a href="#">VBAT register file</a>                    | 32-byte register file that is accessible during all power modes and is powered by VBAT.   |
| <a href="#">Serial programming interface (EzPort)</a> | Same serial interface as, and subset of, the command set used by industry-standard SPI flash memories. Provides the ability to read, erase, and program flash memory and reset command to boot the system after flash programming.  |
| <a href="#">FlexBus</a>                               | External bus interface with multiple independent, user-programmable chip-select signals that can interface with external SRAM, PROM, EPROM, EEPROM, flash, and other peripherals via 8-, 16- and 32-bit port sizes. Configurations include multiplexed or non-multiplexed address and data buses using 8-bit, 16-bit, 32-bit, and 16-byte line-sized transfers. |
| <a href="#">NAND flash controller</a>                 | 8-bit and 16-bit NAND flash interface with page sizes of 512 bytes, 2 KB, 4 KB, and 8 KB. Supports up to 32-bit ECC error correction.   |
| <a href="#">SDRAM Controller</a>                      | Interface to store and retrieve data from an external SDRAM. Supports glue-less interface to LPDDR, DDR and DDR2 DRAM devices.  |
| <a href="#">SDRAM Controller</a>                      | Interface to store and retrieve data from an external SDRAM. Supports glue-less interface to SDR DRAM devices with up to 32-bit wide data and 16MB per chip select.   |

## 2.2.4 Clocks

The following clock modules are available on this device.

**Table 2-5. Clock modules**

| Module                                      | Description  |
|---|--|
| <a href="#">Multi-clock generator (MCG)</a> | The MCG provides several clock sources for the MCU that include: <ul style="list-style-type: none"> <li>• Phase-locked loop (PLL) — Voltage-controlled oscillator (VCO)</li> <li>• Frequency-locked loop (FLL) — Digitally-controlled oscillator (DCO)</li> <li>• Internal reference clocks — Can be used as a clock source for other on-chip peripherals</li> </ul> |
| <a href="#">System oscillator</a>           | The system oscillator, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.  |
| <a href="#">Real-time clock oscillator</a>  | The RTC oscillator has an independent power supply and supports a 32 kHz crystal oscillator to feed the RTC clock. Optionally, the RTC oscillator can replace the system oscillator as the main oscillator source.   |

## 2.2.5 Security and Integrity modules

The following security and integrity modules are available on this device:

**Table 2-6. Security and integrity modules**

| Module                                       | Description   |
|--|---|
| Cryptographic acceleration unit (CAU)        | Supports DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms via simple C calls to optimized security functions provided by Freescale.   |
| Random number generator (RNG)                | Supports the key generation algorithm defined in the Digital Signature Standard.  |
| Cyclic Redundancy Check (CRC)                | Hardware CRC generator circuit using 16/32-bit shift register. Error detection for all single, double, odd, and most multi-bit errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register. |
| DryIce (tamper detection and secure storage) | The DryIce module includes a 32-byte secure memory that is asynchronously erased on any tamper detect. In addition, it can optionally force a System Reset and/or invalidate the Real Time Clock.   |

## 2.2.6 Analog modules

The following analog modules are available on this device:

**Table 2-7. Analog modules**

| Module   | Description   |
|--|---|
| 16-bit analog-to-digital converters (ADC) and programmable-gain amplifiers (PGA) | 16-bit successive-approximation ADC designed with integrated programmable gain amplifiers (PGA)   |
| Analog comparators (CMP)   | Compares two analog input voltages across the full range of the supply voltage.   |
| 6-bit digital-to-analog converters (DAC)   | 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed.  |
| 12-bit digital-to-analog converters (DAC)  | Low-power general-purpose DAC, whose output can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.   |
| Voltage reference (VREF)   | Supplies an accurate voltage output that is trimmable in 0.5 mV steps. The VREF can be used in medical applications, such as glucose meters, to provide a reference voltage to biosensors or as a reference to analog peripherals, such as the ADC, DAC or CMP. |

## 2.2.7 Timer modules

The following timer modules are available on this device:

**Table 2-8. Timer modules**

| Module  | Description   |
|---|---|
| <a href="#">Programmable delay block (PDB)</a>  | <ul style="list-style-type: none"> <li>• 16-bit resolution</li> <li>• 3-bit prescaler</li> <li>• Positive transition of trigger event signal initiates the counter</li> <li>• Supports two triggered delay output signals, each with an independently-controlled delay from the trigger event</li> <li>• Outputs can be OR'd together to schedule two conversions from one input trigger event and can schedule precise edge placement for a pulsed output. This feature is used to generate the control signal for the CMP windowing feature and output to a package pin if needed for applications, such as critical conductive mode power factor correction.</li> <li>• Continuous-pulse output or single-shot mode supported, each output is independently enabled, with possible trigger events</li> <li>• Supports bypass mode</li> <li>• Supports DMA</li> </ul>   |
| <a href="#">Flexible timer modules (FTM)</a>    | <ul style="list-style-type: none"> <li>• Selectable FTM source clock, programmable prescaler</li> <li>• 16-bit counter supporting free-running or initial/final value, and counting is up or up-down</li> <li>• Input capture, output compare, and edge-aligned and center-aligned PWM modes</li> <li>• Operation of FTM channels as pairs with equal outputs, pairs with complimentary outputs, or independent channels with independent outputs</li> <li>• Deadtime insertion is available for each complementary pair</li> <li>• Generation of hardware triggers</li> <li>• Software control of PWM outputs</li> <li>• Up to 4 fault inputs for global fault control</li> <li>• Configurable channel polarity</li> <li>• Programmable interrupt on input capture, reference compare, overflowed counter, or detected fault condition</li> <li>• Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event</li> <li>• DMA support for FTM events</li> </ul> |
| <a href="#">Periodic interrupt timers (PIT)</a> | <ul style="list-style-type: none"> <li>• Four general purpose interrupt timers</li> <li>• Interrupt timers for triggering ADC conversions</li> <li>• 32-bit counter resolution</li> <li>• DMA support</li> </ul>  |

## 2.2.8 Communication interfaces

The following communication interfaces are available on this device:

**Table 2-9. Communication modules**

| Module  | Description   |
|---|---|
| Ethernet MAC with IEEE 1588 capability (ENET)       | 10/100 MB/s Ethernet MAC (MII and RMII) with hardware support for IEEE 1588   |
| USB OTG (low-/full-speed)                           | USB 2.0 compliant module with support for host, device, and On-The-Go modes. Includes an on-chip transceiver for full and low speeds.   |
| USB OTG (low-/full-/high-speed)                     | USB 2.0 compliant module with support for host, device, and On-The-Go modes. Provides ULPI interface for low, full, and high speeds.  |
| USB Device Charger Detect (USBDCD)                  | The USBDCD monitors the USB data lines to detect a smart charger meeting the USB Battery Charging Specification Rev1.2. This information allows the MCU to better manage the battery charging IC in a portable device.  |
| USB voltage regulator                               | Up to 5 V regulator input typically provided by USB VBUS power with 3.3 V regulated output that powers on-chip USB subsystem, capable of sourcing 120 mA to external board components.  |
| Controller Area Network (CAN)                       | Supports the full implementation of the CAN Specification Version 2.0, Part B   |
| Serial peripheral interface (SPI)                   | Synchronous serial bus for communication to an external device  |
| Inter-integrated circuit (I2C)                      | Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.   |
| Universal asynchronous receiver/transmitters (UART) | Asynchronous serial bus communication interface with programmable 8- or 9-bit data format and support of CEA709.1-B (LON), ISO 7816 smart card interface  |
| Secure Digital host controller (SDHC)               | Interface between the host system and the SD, SDIO, MMC, or CE-ATA cards. The SDHC acts as a bridge, passing host bus transactions to the cards by sending commands and performing data accesses to/from the cards. It handles the SD, SDIO, MMC, and CE-ATA protocols at the transmission level.                         |
| I2S   | The I <sup>2</sup> S is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices, such as standard codecs, digital signal processors (DSPs), microprocessors, peripherals, and audio codecs that implement the inter-IC sound bus (I <sup>2</sup> S) and the Intel® AC97 standards |

## 2.2.9 Human-machine interfaces

The following human-machine interfaces (HMI) are available on this device:

**Table 2-10. HMI modules**

| Module                              | Description   |
|-------------------------------------|---|
| General purpose input/output (GPIO) | All general purpose input or output (GPIO) pins are capable of interrupt and DMA request generation.                                  |
| Capacitive touch sense input (TSI)  | Contains up to 16 channel inputs for capacitive touch sensing applications. Operation is available in low-power modes via interrupts. |

## 2.3 Orderable part numbers

The following table summarizes the part numbers of the devices covered by this document.

**Table 2-11. Orderable part numbers summary**

| Freescale part number | CPU frequency | Pin count | Package | Total flash memory | Program flash | EEPROM | SRAM   | GPIO |
|-----------------------|---------------|-----------|---------|--------------------|---------------|--------|--------|------|
| MK61FX512VMD12        | 120 MHz       | 144       | MAPBGA  | 1 MB               | 512 KB        | 16 KB  | 128 KB | 95   |
| MK61FN1M0VMD12        | 120 MHz       | 144       | MAPBGA  | 1 MB               | 1 MB          | —      | 128 KB | 95   |
| MK61FX512VMD15        | 150 MHz       | 144       | MAPBGA  | 1 MB               | 512 KB        | 16 KB  | 128 KB | 95   |
| MK61FN1M0VMD15        | 150 MHz       | 144       | MAPBGA  | 1 MB               | 1 MB          | —      | 128 KB | 95   |
| MK61FN1M0CAA12        | 120 MHz       | 143       | WLCSP   | 1 MB               | 1 MB          | —      | 128 KB | 79   |

Orderable part numbers

# Chapter 3

## Chip Configuration

### 3.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- module block diagrams showing immediate connections within the device,
- specific module-to-module interactions not necessarily discussed in the individual module chapters, and
- links for more information.

### 3.2 Core modules

#### 3.2.1 ARM Cortex-M4 Core Configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by ARM and can be found at [arm.com](http://arm.com).

**Figure 3-1. Core configuration**

**Table 3-1. Reference links to related information**

| Topic                               | Related module   | Reference  |
|-------------------------------------|--|--|

| System/instruction/data bus module  | SRAM   | <a href="#">SRAM</a>                                     |
| Debug                               | IEEE 1149.1 JTAG<br>Serial Wire Debug (SWD)<br>ARM Real-Time Trace Interface | <a href="#">Debug</a>                                    |
| Interrupts                          | Nested Vectored Interrupt Controller (NVIC)                                  | <a href="#">NVIC</a>                                     |
| Private Peripheral Bus (PPB) module | Miscellaneous Control Module (MCM)   | <a href="#">MCM</a>                                      |
| Private Peripheral Bus (PPB) module | Memory-Mapped Cryptographic Acceleration Unit (MMCAU)                        | <a href="#">MMCAU</a>                                    |
| Private Peripheral Bus (PPB) module | Single-precision floating point unit (FPU)                                   | <a href="#">FPU</a>                                      |

### 3.2.1.1 Buses, interconnects, and interfaces

The ARM Cortex-M4 core has four buses as described in the following table.

**Table 3-2. Buses of ARM Cortex-M4 core and their description**

| Bus name                     | Description  |
|------------------------------|--|
| Instruction code (ICODE) bus | The ICODE and DCODE buses are muxed. This muxed bus is called the CODE bus and is connected to the crossbar switch via a single master port. In addition, the CODE bus is also tightly coupled to the lower half of the system RAM (SRAM_L).   |
| Data code (DCODE) bus        |  |
| System bus                   | The system bus is connected to a separate master port on the crossbar. In addition, the system bus is tightly coupled to the upper half system RAM (SRAM_U).   |
| Private peripheral (PPB) bus | The PPB provides access to these modules: <ul style="list-style-type: none"> <li>• ARM modules such as the NVIC, ETM, ITM, DWT, FBP, and ROM table</li> <li>• Freescale Miscellaneous Control Module (MCM)</li> <li>• Memory-Mapped Cryptographic Acceleration Unit (MMCAU)</li> </ul> |

### 3.2.1.2 System Tick Timer

The System Tick Timer's clock source is always the core clock, FCLK. This results in the following:

- The CLKSOURCE bit in SysTick Control and Status register is always set to select the core clock.
- Because the timing reference (FCLK) is a variable frequency, the TENMS bit in the SysTick Calibration Value Register is always zero.
- The NOREF bit in SysTick Calibration Value Register is always set, implying that FCLK is the only available source of reference timing.

### 3.2.1.3 Debug facilities

This device has extensive debug capabilities including run control and tracing capabilities. The standard ARM debug port that supports JTAG and SWD interfaces. Also the cJTAG interface is supported on this device.

### 3.2.1.4 Caches

This device includes two 8 KB of combined data/ instructions caches to minimize the performance impact of memory access latencies. One for the system bus and one for I/D bus.

Features of the cache are:

- 2-way set associative
- 4 word lines

- Lines can be individually flushed
- Entire cache can be flushed at once

### 3.2.1.4.1 Low Power

The caches are powered down in LLS and VLLSx modes. The caches need to be flushed before being powered down. This affects the time it takes for the system to go into the new mode but not the wakeup time.

### 3.2.1.4.2 Control

For control purposes the cache can be in one of these states:

1. Write Back \ Write Allocate (WBWA)
2. Write Through
3. No cache

For each defined region there will be 2 bits allocated on the control register that determines the cache state for the memory region associated with this section. The user can only "lower" the cache attribute, given the fixed relationship of WBWA > WT > NC - so, you can demote a WBWA region to either WT or NC, you can demote a WT space to NC. In order to change the state upwards a system reset is required.

The 1Gb space allocated to the DRAM and Flexbus will be split in 16 MB regions and 2 bits assigned to the control state of each region. A total of 128 bits, distributed in 4 32-bit registers will be used for this control.

### 3.2.1.5 Core privilege levels

The ARM documentation uses different terms than this document to distinguish between privilege levels.

| If you see this term... | it also means this term... |
|-------------------------|----------------------------|
| Privileged              | Supervisor                 |
| Unprivileged or user    | User                       |

## 3.2.2 Nested Vectored Interrupt Controller (NVIC) Configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by ARM and can be found at [arm.com](http://arm.com).

Figure 3-2. NVIC configuration

Table 3-3. Reference links to related information

| Topic                        | Related module                              | Reference  |
|------------------------------|---|--|
| Full description             | Nested Vectored Interrupt Controller (NVIC) | <a href="#">ARM Cortex-M4 Technical Reference Manual</a> |
| System memory map            |   | <a href="#">System memory map</a>                        |
| Clocking                     |   | <a href="#">Clock distribution</a>                       |
| Power management             |   | <a href="#">Power management</a>                         |
| Private Peripheral Bus (PPB) | ARM Cortex-M4 core                          | <a href="#">ARM Cortex-M4 core</a>                       |

### 3.2.2.1 Interrupt priority levels

This device supports 16 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 4 bits. For example, IPR0 is shown below:

|   |      |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|---|------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|------|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
|   | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R | IRQ3 |    |    |    | 0  |    |    |    | IRQ2 |    |    |    | 0  |    |    |    | IRQ1 |    |    |    | 0  |    |   |   | IRQ0 |   |   |   | 0 |   |   |   |
| W |      |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

### 3.2.2.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external  $\overline{\text{NMI}}$  signal. The pin the  $\overline{\text{NMI}}$  signal is multiplexed on, must be configured for the  $\overline{\text{NMI}}$  function to generate the non-maskable interrupt request.

### 3.2.2.3 Interrupt channel assignments

The interrupt source assignments are defined in the following table.

Core modules

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within ARM's NVIC documentation.

**Table 3-5. Interrupt vector assignments**

| Address                                | Vector | IRQ <sup>1</sup> | NVIC non-IPR register number<br>2 | NVIC IPR register number<br>3 | Source module | Source description                                   |
|--|--------|------------------|-----------------------------------|-------------------------------|---------------|--|
| <b>ARM Core System Handler Vectors</b> |        |                  |                                   |                               |               |  |
| 0x0000_0000                            | 0      | —                | —                                 | —                             | ARM core      | Initial Stack Pointer                                |
| 0x0000_0004                            | 1      | —                | —                                 | —                             | ARM core      | Initial Program Counter                              |
| 0x0000_0008                            | 2      | —                | —                                 | —                             | ARM core      | Non-maskable Interrupt (NMI)                         |
| 0x0000_000C                            | 3      | —                | —                                 | —                             | ARM core      | Hard Fault   |
| 0x0000_0010                            | 4      | —                | —                                 | —                             | ARM core      | MemManage Fault                                      |
| 0x0000_0014                            | 5      | —                | —                                 | —                             | ARM core      | Bus Fault  |
| 0x0000_0018                            | 6      | —                | —                                 | —                             | ARM core      | Usage Fault  |

| 0x0000_01DC | 119    | 103              | 3   | 25                                    | ADC3                        | —                                       |
| 0x0000_01E0 | 120    | 104              | 3   | 26                                    | I <sup>2</sup> S1           | Transmit                                |

Table continues on the next page...

**Table 3-5. Interrupt vector assignments (continued)**

| Address     | Vector | IRQ <sup>1</sup> | NVIC non-IPR register number <sup>2</sup> | NVIC IPR register number <sup>3</sup> | Source module     | Source description |
|-------------|--------|------------------|---|---------------------------------------|-------------------|--------------------|
| 0x0000_01E4 | 121    | 105              | 3   | 26                                    | I <sup>2</sup> S1 | Receive            |

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is:  $IRQ \div 32$
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is:  $IRQ \div 4$
4. This interrupt can only be pended or cleared via the NVIC registers.

### 3.2.2.3.1 Determining the bitfield and register location for configuring a particular interrupt

Suppose you need to configure the low-power timer (LPTMR) interrupt. The following table is an excerpt of the LPTMR row from [Interrupt channel assignments](#).

**Table 3-6. LPTMR interrupt vector assignment**

| Address     | Vector | IRQ <sup>1</sup> | NVIC non-IPR register number <sup>2</sup> | NVIC IPR register number <sup>3</sup> | Source module   | Source description |
|-------------|--------|------------------|---|---------------------------------------|-----------------|--------------------|
| 0x0000_0194 | 101    | 85               | 2   | 21                                    | Low Power Timer | —                  |

1. Indicates the NVIC's interrupt source number.
2. Indicates the NVIC's ISER, ICER, ISPR, ICPR, and IABR register number used for this IRQ. The equation to calculate this value is:  $IRQ \div 32$
3. Indicates the NVIC's IPR register number used for this IRQ. The equation to calculate this value is:  $IRQ \div 4$

- The NVIC registers you would use to configure the interrupt are:
  - NVICISER2
  - NVICICER2
  - NVICISPR2
  - NVICICPR2
  - NVICIABR2
  - NVICIPR21
- To determine the particular IRQ's bitfield location within these particular registers:
  - NVICISER2, NVICICER2, NVICISPR2, NVICICPR2, NVICIABR2 bit location =  $IRQ \bmod 32 = 21$
  - NVICIPR21 bitfield starting location =  $8 * (IRQ \bmod 4) + 4 = 12$

Since the NVICIPR bitfields are 4-bit wide (16 priority levels), the NVICIPR21 bitfield range is 12-15

Therefore, the following bitfield locations are used to configure the LPTMR interrupts:

- NVICISER2[21]
- NVICICER2[21]
- NVICISPR2[21]
- NVICICPR2[21]
- NVICIABR2[21]
- NVICIPR21[15:12]

### 3.2.3 Asynchronous Wake-up Interrupt Controller (AWIC) Configuration

This section summarizes how the module has been configured in the chip. Full documentation for this module is provided by ARM and can be found at [arm.com](http://arm.com).

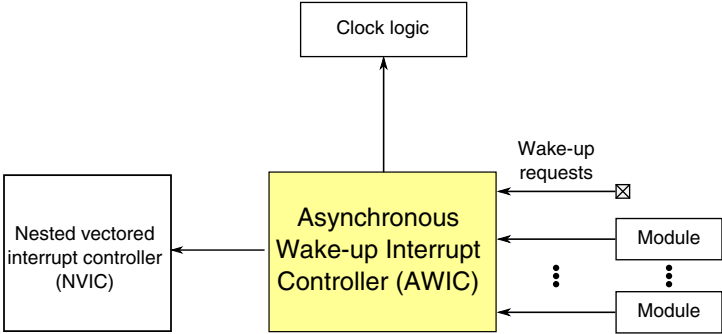

Figure 3-3. Asynchronous Wake-up Interrupt Controller configuration

### 3.2.3.1 Wake-up sources

The device uses the following internal and external inputs to the AWIC module.

**Table 3-8. AWIC Stop and VLPS Wake-up Sources**

| Wake-up source          | Description   |
|-------------------------|---|
| Available system resets | RESET pin and WDOG when LPO is its clock source, and JTAG                       |
| Low-voltage detect      | Mode Controller   |
| Low-voltage warning     | Mode Controller   |
| Pin interrupts          | Port Control Module - Any enabled pin interrupt is capable of waking the system |
| ADCx                    | The ADC is functional when using internal clock source                          |
| CMPx                    | Since no system clocks are available, functionality is limited                  |
| I <sup>2</sup> C        | Address match wakeup  |
| UART                    | Active edge on RXD  |
| USB FS/LS Controller    | Wakeup  |
| USB HS/FS/LS Controller | Wakeup  |
| LPTMR                   | Functional when using clock source which is active in Stop and VLPS modes       |
| RTC                     | Functional in Stop/VLPS modes   |
| Ethernet                | Magic Packet wakeup   |
| SDHC                    | Wakeup  |
| I2S (SAI)               | Functional when using an external bit clock or external master clock            |
| ENET 1588 Timer         | Functional when using clock source which is active in Stop and VLPS modes       |
| TSI                     | Wakeup  |
| CAN                     | Wakeup on edge (CANx_RX)  |
| Tamper detect           | Interrupt or a reset  |
| NMI                     | Non-maskable interrupt  |

### 3.2.4 FPU Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 3-4. FPU configuration

Table 3-9. Reference links to related information

| Topic                        | Related module     | Reference  |

|                   | Low-Leakage Wakeup Unit (LLWU) | <a href="#">LLWU</a>                   |
|                   | Reset Control Module (RCM)     | <a href="#">Reset</a>                  |

### 3.3.4 Low-Leakage Wake-up Unit (LLWU) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

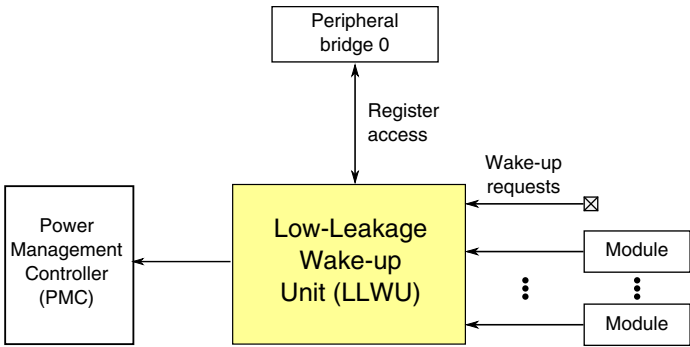

Figure 3-9. Low-Leakage Wake-up Unit configuration

Table 3-14. Reference links to related information

| Topic             | Related module                    | Reference   |
|-------------------|-----------------------------------|---|
| Full description  | LLWU                              | <a href="#">LLWU</a>                              |
| System memory map |                                   | <a href="#">System memory map</a>                 |
| Clocking          |                                   | <a href="#">Clock distribution</a>                |
| Power management  |                                   | <a href="#">Power management chapter</a>          |
|                   | Power Management Controller (PMC) | <a href="#">Power Management Controller (PMC)</a> |
|                   | Mode Controller                   | <a href="#">Mode Controller</a>                   |
| Wake-up requests  |                                   | <a href="#">LLWU wake-up sources</a>              |

### 3.3.4.1 Wake-up Sources

This chip uses the following internal peripheral and external pin inputs as wakeup sources to the LLWU module:

- LLWU\_P0-15 are external pin inputs. Any digital function multiplexed on the pin can be selected as the wakeup source. See the chip's signal multiplexing table for the digital signal options.
- LLWU\_M0IF-M7IF are connections to the internal peripheral interrupt flags.

**NOTE**

$\overline{\text{RESET}}$  is also a wakeup source, depending on the bit setting in the LLWU\_RST register. On devices where  $\overline{\text{RESET}}$  is not a dedicated pin, it must also be enabled in the explicit port mux control.

**Table 3-15. Wakeup sources for LLWU inputs**

| Input    | Wakeup source                 | Input     | Wakeup source            |
|----------|-------------------------------|-----------|--------------------------|
| LLWU_P0  | PTE1/LLWU_P0 pin              | LLWU_P12  | PTD0/LLWU_P12 pin        |
| LLWU_P1  | PTE2/LLWU_P1 pin              | LLWU_P13  | PTD2/LLWU_P13 pin        |
| LLWU_P2  | PTE4/LLWU_P2 pin              | LLWU_P14  | PTD4/LLWU_P14 pin        |
| LLWU_P3  | PTA4/LLWU_P3 pin <sup>1</sup> | LLWU_P15  | PTD6/LLWU_P15 pin        |
| LLWU_P4  | PTA13/LLWU_P4 pin             | LLWU_M0IF | LPTMR <sup>2</sup>       |
| LLWU_P5  | PTB0/LLWU_P5 pin              | LLWU_M1IF | CMP0 <sup>2</sup>        |
| LLWU_P6  | PTC1/LLWU_P6 pin              | LLWU_M2IF | CMP1 <sup>2</sup>        |
| LLWU_P7  | PTC3/LLWU_P7 pin              | LLWU_M3IF | CMP2/CMP3 <sup>2</sup>   |
| LLWU_P8  | PTC4/LLWU_P8 pin              | LLWU_M4IF | TSI <sup>2</sup>         |
| LLWU_P9  | PTC5/LLWU_P9 pin              | LLWU_M5IF | RTC Alarm <sup>2</sup>   |
| LLWU_P10 | PTC6/LLWU_P10 pin             | LLWU_M6IF | Reserved                 |
| LLWU_P11 | PTC11/LLWU_P11 pin            | LLWU_M7IF | RTC Seconds <sup>2</sup> |

1. The `EZP_CS` signal is checked only on *Chip Reset not VLLS*, so a VLLS wakeup via a non-reset source does not cause EzPort mode entry. If NMI was enabled on entry to LLS/VLLS, asserting the NMI pin generates an NMI interrupt on exit from the low power mode.
2. Requires the peripheral and the peripheral interrupt to be enabled. The LLWU's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.

### 3.3.5 MCM Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-10. MCM configuration**

**Table 3-16. Reference links to related information**

| Topic                        | Related module                     | Reference                          |
|------------------------------|------------------------------------|------------------------------------|

| Crossbar switch master | NFC                | <a href="#">NFC</a>                |
| Crossbar switch slave  | Flash              | <a href="#">Flash</a>              |
| Crossbar switch slave  | SRAM backdoor      | <a href="#">SRAM backdoor</a>      |
| Crossbar switch slave  | Peripheral bridges | <a href="#">Peripheral bridge</a>  |
| Crossbar switch slave  | GPIO controller    | <a href="#">GPIO controller</a>    |
| Crossbar switch slave  | FlexBus/           | <a href="#">FlexBus</a>            |
| Crossbar switch slave  | DDR Controller     | <a href="#">DDR Controller</a>     |

### 3.3.6.1 Crossbar Switch Master Assignments

The masters connected to the crossbar switch are assigned as follows:

| Master module       | Master port number |
|---------------------|--------------------|
| ARM core code bus   | 0                  |
| ARM core system bus | 1                  |
| DMA/EzPort          | 2                  |
| SDHC/NFC/USB FS     | 3                  |
| USB HS              | 6                  |
| Ethernet            | 7                  |

#### NOTE

The DMA and EzPort share a master port. Since these modules never operate at the same time, no configuration or arbitration explanations are necessary.

### 3.3.6.2 Crossbar Switch Slave Assignments

The slaves connected to the crossbar switch are assigned as follows:

| Slave module                          | Slave port number | Protected by MPU?                 |
|---------------------------------------|-------------------|-----------------------------------|
| Flash memory controller               | 0                 | Yes                               |
| SRAM backdoor                         | 1                 | Yes                               |
| Peripheral bridge 0 <sup>1</sup>      | 2                 | No. Protection built into bridge. |
| Peripheral bridge 1/GPIO <sup>1</sup> | 3                 | No. Protection built into bridge. |
| FlexBus                               | 4                 | Yes                               |

1. See [System memory map](#) for access restrictions.

### 3.3.6.3 PRS register reset values

The AXBS\_PRS<sub>n</sub> registers reset to 7654\_3210h .

## 3.3.7 Memory Protection Unit (MPU) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

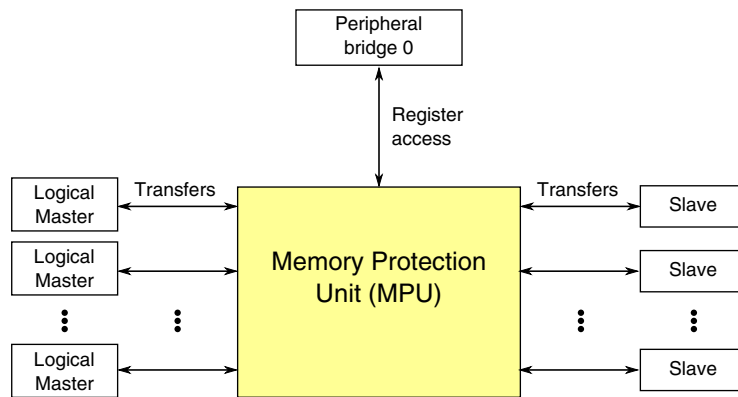

Figure 3-12. Memory Protection Unit configuration

Table 3-18. Reference links to related information

| Topic             | Related module               | Reference                                  |
|-------------------|------------------------------|--|
| Full description  | Memory Protection Unit (MPU) | <a href="#">MPU</a>                        |
| System memory map |                              | <a href="#">System memory map</a>          |
| Clocking          |                              | <a href="#">Clock distribution</a>         |
| Power management  |                              | <a href="#">Power management</a>           |
| Logical masters   |                              | <a href="#">Logical master assignments</a> |
| Slave modules     |                              | <a href="#">Slave module assignments</a>   |

### 3.3.7.1 MPU Slave Port Assignments

The memory-mapped resources protected by the MPU are:

**Table 3-19. MPU Slave Port Assignments**

| Source                | MPU Slave Port Assignment | Destination      |
|-----------------------|---------------------------|------------------|
| Crossbar slave port 0 | MPU slave port 0          | Flash Controller |
| Crossbar slave port 1 | MPU slave port 1          | SRAM backdoor    |
| Code Bus              | MPU slave port 2          | SRAM_L frontdoor |
| System Bus            | MPU slave port 3          | SRAM_U frontdoor |
| Crossbar slave port 4 | MPU slave port 4          | FlexBus          |

### 3.3.7.2 MPU Logical Bus Master Assignments

The logical bus master assignments for the MPU are:

**Table 3-20. MPU Logical Bus Master Assignments**

| MPU Logical Bus Master Number | Bus Master      |
|-------------------------------|-----------------|
| 0                             | Core            |
| 1                             | Debugger        |
| 2                             | DMA             |
| 3                             | SDHC/NFC/USB FS |
| 4                             | none            |
| 5                             | none            |
| 6                             | USB HS          |
| 7                             | ENET            |

### 3.3.7.3 MPU Access Violation Indications

Access violations detected by the MPU are signaled to the appropriate bus master as shown below:

**Table 3-21. Access Violation Indications**

| Bus Master | Core Indication   |
|------------|---|
| Core       | Bus fault (interrupt vector #5) Note: To enable bus faults set the core's System Handler Control and State Register's BUSFAULTENA bit. If this bit is not set, MPU violations result in a hard fault (interrupt vector #3). |
| Debugger   | The STICKYERROR flag is set in the Debug Port Control/Status Register.  |

*Table continues on the next page...*

**Table 3-21. Access Violation Indications (continued)**

| Bus Master | Core Indication      |
|------------|----------------------|
| DMA        | Interrupt vector #32 |
| Ethernet   | Interrupt vector #94 |
| USB_OTG    | Interrupt vector #89 |
| SDHC       | Interrupt vector #96 |

### 3.3.7.4 Reset Values for RGD0 Registers

At reset, the MPU is enabled with a single region descriptor (RGD0) that maps the entire 4 GB address space with read, write and execute permissions given to the core, debugger and the DMA bus masters.

The following table shows the chip-specific reset values for RGD0 and RGDAAC0.

**Table 3-22. Reset Values for RGD0 Registers**

| Register   | Reset value |
|------------|-------------|
| RGD0_WORD0 | 0000_0000h  |
| RGD0_WORD1 | FFFF_FFFFh  |
| RGD0_WORD2 | 0061_F7DFh  |
| RGD0_WORD3 | 0000_0001h  |
| RGDAAC0    | 0061_F7DFh  |

### 3.3.7.5 Write Access Restrictions for RGD0 Registers

In addition to configuring the initial state of RGD0, the MPU implements further access control on writes to the RGD0 registers. Specifically, the MPU assigns a priority scheme where the debugger is treated as the highest priority master followed by the core and then all the remaining masters.

The MPU does not allow writes from the core to affect the RGD0 start or end addresses nor the permissions associated with the debugger; it can only write the permission fields associated with the other masters.

These protections (summarized below) guarantee that the debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

**Table 3-23. Write Access to RGD0 Registers**

| Bus Master        | Write Access?   |
|-------------------|---|
| Core              | Partial. The Core cannot write to the following registers or register fields: <ul style="list-style-type: none"> <li>• RGD0_WORD0, RGD0_WORD1, RGD0_WORD3</li> <li>• RGD0_WORD2[M1SM, M1UM]</li> <li>• RGDAAC0[M1SM, M1UM]</li> </ul> <p><b>NOTE:</b> Changes to the RGD0_WORD2 alterable fields should be done via a write to RGDAAC0.</p> |
| Debugger          | Yes   |
| All other masters | No  |

### 3.3.8 Peripheral Bridge Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-13. Peripheral bridge configuration**

**Table 3-24. Reference links to related information**

| Topic             | Related module                | Reference                                     |
|-------------------|-------------------------------|---|
| Full description  | Peripheral bridge (AIPS-Lite) | <a href="#">Peripheral bridge (AIPS-Lite)</a> |
| System memory map |                               | <a href="#">System memory map</a>             |
| Clocking          |                               | <a href="#">Clock Distribution</a>            |
| Crossbar switch   | Crossbar switch               | <a href="#">Crossbar switch</a>               |

#### 3.3.8.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

### 3.3.8.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See [AIPS0 Memory Map](#) and [AIPS1 Memory Map](#) for the memory slot assignment for each module.

### 3.3.8.3 MPRA register

Each of the two peripheral bridges supports up to 8 crossbar switch masters, each assigned to a MPROTx field in the MPRA register. However, fewer are supported on this device. See [Crossbar switch](#) for details of the master port assignments for this device.

### 3.3.8.4 AIPS\_Lite MPRA register reset value

- AIPS<sub>x</sub>\_MPRA reset value is 0x7770\_0000

Therefore, masters 0, 1, and 2 are trusted bus masters after reset.

### 3.3.8.5 PACR registers

Each of the two peripheral bridges support up to 128 peripherals each assigned to an PACRx field within the PACRA-PACRP registers. However, fewer peripherals are supported on this device. See [AIPS0 Memory Map](#) and [AIPS1 Memory Map](#) for details of the peripheral slot assignments for this device. Unused PACRx fields are reserved.

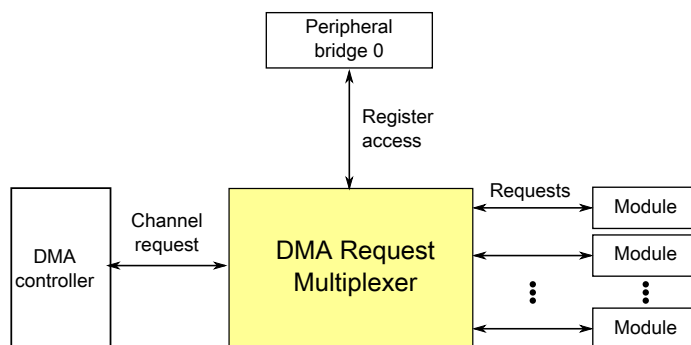

### 3.3.8.6 AIPS\_Lite PACRE-P register reset values

The AIPS<sub>x</sub>\_PACRE-P reset values depend on if the module is available on your particular device. For each populated slot in slots 32-127 in [Peripheral Bridge 0 \(AIPS-Lite 0\) Memory Map](#) and [Peripheral Bridge 1 \(AIPS-Lite 1\) Memory Map](#), the corresponding module's PACR[32:127] field resets to 0x4.

## 3.3.9 DMA request multiplexer configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-14. DMA request multiplexer configuration**

**Table 3-25. Reference links to related information**

| Topic             | Related module          | Reference                           |
|-------------------|-------------------------|-------------------------------------|

### 3.3.9.1 DMA MUX request sources

This device includes two DMA request MUXes that allows up to 126 DMA request signals to be mapped to any of the 32 DMA channels. Because of the mux there is not a hard correlation between any of the DMA request sources and a specific DMA channel. The first MUX is connected to channels 0-15 and the second MUX is connected to channels 16-31. To allow for flexibility and optimal usage of the available DMA channels some of the DMA request sources are available on both muxes.

**Table 3-26. DMA request sources - MUX 0**

| Source number | Source module | Source description            |
|---------------|---------------|-------------------------------|
| 0             | —             | Channel disabled <sup>1</sup> |
| 1             | Reserved      | Not used                      |
| 2             | UART0         | Receive                       |
| 3             | UART0         | Transmit                      |
| 4             | UART1         | Receive                       |
| 5             | UART1         | Transmit                      |
| 6             | UART2         | Receive                       |

| 61            | DMA MUX       | Always enabled     |
| 62            | DMA MUX       | Always enabled     |
| 63            | DMA MUX       | Always enabled     |

1. Configuring a DMA channel to select source 0 or any of the reserved sources disables that DMA channel.

### 3.3.9.2 DMA transfers via PIT trigger

The PIT module can trigger a DMA transfer on the first four DMA channels. The assignments are detailed at [PIT/DMA Periodic Trigger Assignments](#).

### 3.3.10 DMA Controller Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-15. DMA Controller configuration**

**Table 3-28. Reference links to related information**

### 3.3.11 External Watchdog Monitor (EWM) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-16. External Watchdog Monitor configuration**
**Table 3-29. Reference links to related information**

| Topic               | Related module                  | Reference                           |
|---------------------|---------------------------------|-------------------------------------|
| Full description    | External Watchdog Monitor (EWM) | <a href="#">EWM</a>                 |
| System memory map   |                                 | <a href="#">System memory map</a>   |
| Clocking            |                                 | <a href="#">Clock distribution</a>  |
| Power management    |                                 | <a href="#">Power management</a>    |
| Signal multiplexing | Port Control Module             | <a href="#">Signal multiplexing</a> |

#### 3.3.11.1 EWM clocks

This table shows the EWM clocks and the corresponding chip clocks.

**Table 3-30. EWM clock connections**

| Module clock    | Chip clock      |
|-----------------|-----------------|
| Low Power Clock | 1 kHz LPO Clock |

### 3.3.11.2 EWM low-power modes

This table shows the EWM low-power modes and the corresponding chip low-power modes.

**Table 3-31. EWM low-power modes**

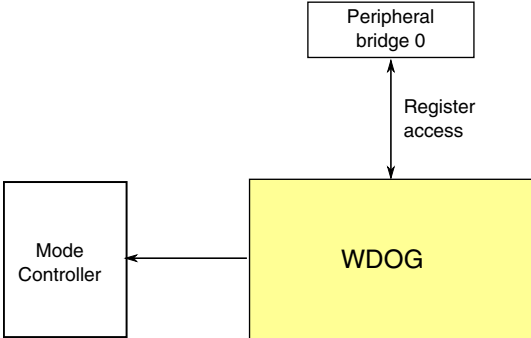

| Module mode | Chip mode       |
|-------------|-----------------|
| Wait        | Wait, VLPW      |
| Stop        | Stop, VLPS, LLS |

### 3.3.11.3 $\overline{\text{EWM\_OUT}}$ pin state in low power modes

During Wait, Stop and Power Down modes the  $\overline{\text{EWM\_OUT}}$  pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

## 3.3.12 Watchdog Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-17. Watchdog configuration**

**Table 3-32. Reference links to related information**

| Topic             | Related module       | Reference                              |
|-------------------|----------------------|--|
| Full description  | Watchdog             | <a href="#">Watchdog</a>               |

| Power management  |                      | <a href="#">Power management</a>       |
|                   | Mode Controller (MC) | <a href="#">System Mode Controller</a> |

**3.3.12.1 WDOG clocks**

This table shows the WDOG module clocks and the corresponding chip clocks.

**Table 3-33. WDOG clock connections**

| Module clock     | Chip clock      |
|------------------|-----------------|
| LPO Oscillator   | 1 kHz LPO Clock |
| Alt Clock        | Bus Clock       |
| Fast Test Clock  | Bus Clock       |
| System Bus Clock | Bus Clock       |

**3.3.12.2 WDOG low-power modes**

This table shows the WDOG low-power modes and the corresponding chip low-power modes.

**Table 3-34. WDOG low-power modes**

| Module mode | Chip mode  |
|-------------|------------|
| Wait        | Wait, VLPW |

*Table continues on the next page...*

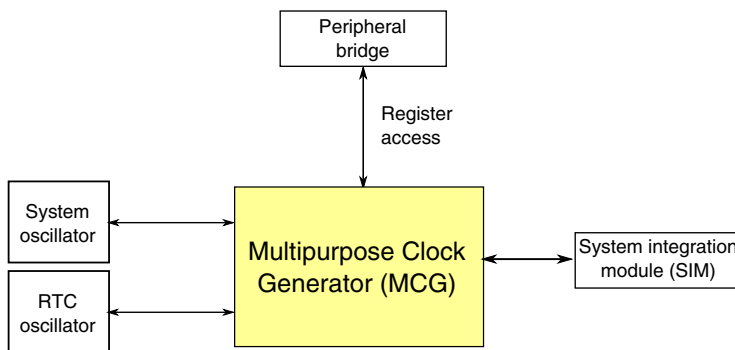

**Table 3-34. WDOG low-power modes (continued)**

| Module mode | Chip mode                              |
|-------------|--|
| Stop        | Stop, VLPS                             |
| Power Down  | LLS(static retained), VLLSx(Power Off) |

## 3.4 Clock modules

### 3.4.1 MCG Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

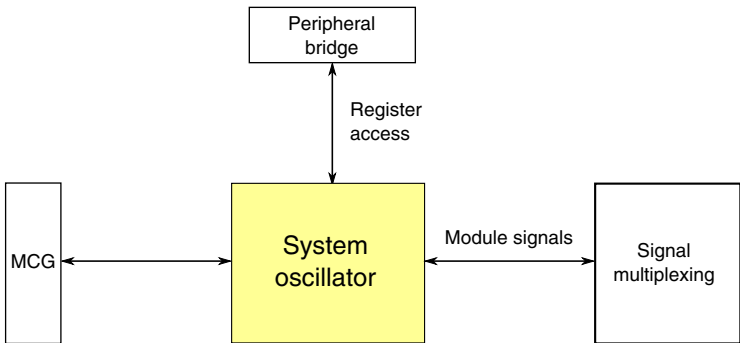

**Figure 3-18. MCG configuration**

**Table 3-35. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | MCG            | <a href="#">MCG</a>                 |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |

### 3.4.2 OSCx Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-19. OSCx configuration**

**Table 3-36. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | OSCx           | <a href="#">OSCx</a>                |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |
| Full description    | MCG            | <a href="#">MCG</a>                 |

### 3.4.2.1 OSC modes of operation with MCG

The MCG's C2 register bits configure the oscillator frequency range. See the OSC and MCG chapters for more details.

### 3.4.3 RTC OSC configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-20. RTC OSC configuration**

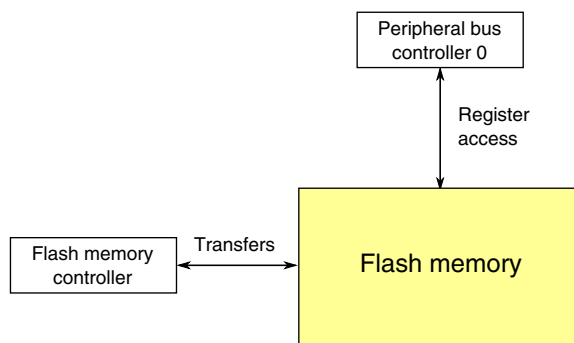

**Table 3-37. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | RTC OSC        | <a href="#">RTC OSC</a>             |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |
| Full description    | MCG            | <a href="#">MCG</a>                 |

## 3.5 Memories and memory interfaces

### 3.5.1 Flash Memory Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-21. Flash memory configuration**

**Table 3-38. Reference links to related information**

| Topic             | Related module          | Reference                               |
|-------------------|-------------------------|---|
| Full description  | Flash memory            | <a href="#">Flash memory</a>            |
| System memory map |                         | <a href="#">System memory map</a>       |
| Clocking          |                         | <a href="#">Clock Distribution</a>      |
| Transfers         | Flash memory controller | <a href="#">Flash memory controller</a> |
| Register access   | Peripheral bridge       | <a href="#">Peripheral bridge</a>       |

### 3.5.1.1 Flash memory types

This device contains the following types of flash memory:

- Program flash memory — non-volatile flash memory that can execute program code
- FlexMemory — encompasses the following memory types:
  - For devices with FlexNVM: FlexNVM — Non-volatile flash memory that can execute program code, store data, or backup EEPROM data
  - For devices with FlexNVM: FlexRAM — RAM memory that can be used as traditional RAM or as high-endurance EEPROM storage, and also accelerates flash programming
  - For devices with only program flash memory: Programming acceleration RAM — RAM memory that accelerates flash programming

### 3.5.1.2 Flash Memory Sizes

The devices covered in this document contain:

- For devices with program flash only: 4 blocks of program flash consisting of 4 KB sectors
- For devices that contain FlexNVM: 2 blocks of program flash consisting of 4 KB sectors
- For devices that contain FlexNVM: 2 blocks of FlexNVM consisting of 4 KB sectors
- For devices that contain FlexNVM: 1 block of FlexRAM

The amounts of flash memory for the devices covered in this document are:

| Device          | Program flash (KB) | Block 0 (P-Flash) address range <sup>1</sup> | FlexNVM (KB) | Block 1 (FlexNVM/ P-Flash) address range <sup>1</sup> | FlexRAM/ Programming Acceleration RAM (KB) | FlexRAM/ Programming Acceleration RAM address range |
|-----------------|--------------------|--|--------------|---|--|---|
| MK61FX512VM D12 | 512                | 0x0000_0000 – 0x0007_FFFF                    | 512          | 0x1000_0000 – 0x1007_FFFF                             | 16   | 0x1400_0000 – 0x1400_3FFF                           |
| MK61FN1M0V MD12 | 1024               | 0x0000_0000 – 0x0007_FFFF                    | —            | 0x0008_0000 – 0x000F_FFFF                             | 16   | 0x1400_0000 – 0x1400_3FFF                           |
| MK61FX512VM D15 | 512                | 0x0000_0000 – 0x0007_FFFF                    | 512          | 0x1000_0000 – 0x1007_FFFF                             | 16   | 0x1400_0000 – 0x1400_3FFF                           |
| MK61FN1M0V MD15 | 1024               | 0x0000_0000 – 0x0007_FFFF                    | —            | 0x0008_0000 – 0x000F_FFFF                             | 16   | 0x1400_0000 – 0x1400_3FFF                           |
| MK61FN1M0C AA12 | 1024               | 0x0000_0000 – 0x0007_FFFF                    | —            | 0x0008_0000 – 0x000F_FFFF                             | 16   | 0x1400_0000 – 0x1400_3FFF                           |

1. For program flash only devices: The addresses shown assume program flash swap is disabled (default configuration).

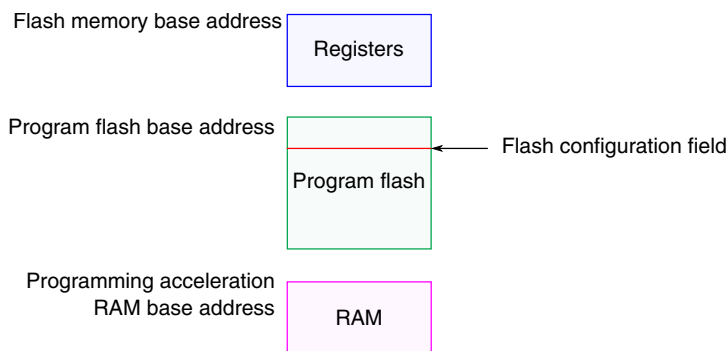

### 3.5.1.3 Flash Memory Size Considerations

Since this document covers devices that contain program flash only and devices that contain program flash and FlexNVM, there are some items to consider when reading the flash memory chapter.

- The flash memory chapter shows a mixture of information depending on the device you are using.
- For the program flash only devices:
  - Two program flash blocks are supported: program flash 1 and program flash 2. The two blocks are contiguous in the system memory map.
  - The program flash blocks support a swap feature in which the starting address of the program flash blocks can be swapped.
  - The programming acceleration RAM is used for the Program Section command.
- For the devices containing program flash and FlexNVM:
  - Since there is only one program flash block, the program flash swap feature is not available.

### 3.5.1.4 Flash Memory Map

The various flash memories and the flash registers are located at different base addresses as shown in the following figure. The base address for each is specified in [System memory map](#).

**Figure 3-22. Flash memory map for devices containing only program flash**

**Figure 3-23. Flash memory map for devices containing FlexNVM**

### 3.5.1.5 Flash Security

How flash security is implemented on this device is described in [Chip Security](#).

### 3.5.1.6 Flash Modes

The flash memory operates in NVM normal and NVM special modes. The flash memory enters NVM special mode when the EzPort is enabled ( $\overline{\text{EZP\_CS}}$  asserted during reset). Otherwise, flash memory operates in NVM normal mode.

### 3.5.1.7 Erase All Flash Contents

An Erase All Flash Blocks operation can be launched by software through a series of peripheral bus writes to flash registers. In addition the entire flash memory may be erased external to the flash memory from the SWJ-DP debug port by setting `DAP_CONTROL[0]`. `DAP_STATUS[0]` is set to indicate the mass erase command has been accepted. `DAP_STATUS[0]` is cleared when the mass erase completes.

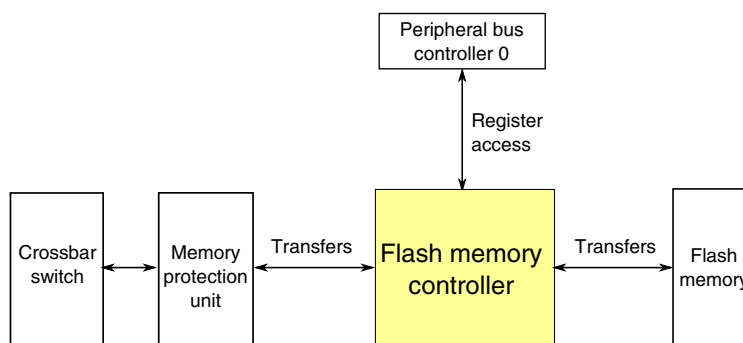

The EzPort can also initiate an erase of flash contents by issuing a bulk erase (BE) command. See the EzPort chapter for more details.

### 3.5.1.8 FTFE\_FOPT Register

The flash memory's FTFE\_FOPT register allows the user to customize the operation of the MCU at boot time. See [FOPT boot options](#) for details of its definition.

## 3.5.2 Flash Memory Controller Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-24. Flash memory controller configuration**

**Table 3-39. Reference links to related information**

| Topic             | Related module          | Reference                               |
|-------------------|-------------------------|---|
| Full description  | Flash memory controller | <a href="#">Flash memory controller</a> |
| System memory map |                         | <a href="#">System memory map</a>       |
| Clocking          |                         | <a href="#">Clock Distribution</a>      |
| Transfers         | Flash memory            | <a href="#">Flash memory</a>            |
| Transfers         | MPU                     | <a href="#">MPU</a>                     |
| Transfers         | Crossbar switch         | <a href="#">Crossbar Switch</a>         |
| Register access   | Peripheral bridge       | <a href="#">Peripheral bridge</a>       |

### 3.5.2.1 Number of masters

The Flash Memory Controller supports up to eight crossbar switch masters. However, this device has a different number of crossbar switch masters. See [Crossbar Switch Configuration](#) for details on the master port assignments.

### 3.5.2.2 Program Flash Swap

On devices that contain program flash memory only, the program flash memory blocks may swap their base addresses.

While not using swap:

- FMC\_PFB01CR controls the lower code addresses (blocks 0-1)
- FMC\_PFB23CR controls the upper code addresses (blocks 2-3)

If swap is used, the opposite is true:

- FMC\_PFB01CR controls the upper code addresses (now in blocks 0-1)
- FMC\_PFB23CR controls the lower code addresses (now in blocks 2-3)

### 3.5.3 SRAM Configuration

This section summarizes how the module has been configured in the chip.

Figure 3-25. SRAM configuration

Table 3-40. Reference links to related information

| Topic             | Related module         | Reference                              |
|-------------------|------------------------|--|
| Full description  | SRAM                   | <a href="#">SRAM</a>                   |
| System memory map |                        | <a href="#">System memory map</a>      |
| Clocking          |                        | <a href="#">Clock Distribution</a>     |
| Transfers         | SRAM controller        | <a href="#">SRAM controller</a>        |
|                   | ARM Cortex-M4 core     | <a href="#">ARM Cortex-M4 core</a>     |
|                   | Memory protection unit | <a href="#">Memory protection unit</a> |

#### 3.5.3.1 SRAM sizes

This device contains SRAM tightly coupled to the ARM Cortex-M4 core. The amount of SRAM for the devices covered in this document is shown in the following table.

| Device         | SRAM (KB) |
|----------------|-----------|
| MK61FX512VMD12 | 128       |
| MK61FN1M0VMD12 | 128       |
| MK61FX512VMD15 | 128       |
| MK61FN1M0VMD15 | 128       |
| MK61FN1M0CAA12 | 128       |

### 3.5.3.2 SRAM Arrays

The on-chip SRAM is split into two equally-sized logical arrays, SRAM\_L and SRAM\_U.

The on-chip RAM is implemented such that the SRAM\_L and SRAM\_U ranges form a contiguous block in the memory map. As such:

- SRAM\_L is anchored to 0x1FFF\_FFFF and occupies the space before this ending address.
- SRAM\_U is anchored to 0x2000\_0000 and occupies the space after this beginning address.

Valid address ranges for SRAM\_L and SRAM\_U are then defined as:

- SRAM\_L = [0x2000\_0000-(SRAM\_size/2)] to 0x1FFF\_FFFF
- SRAM\_U = 0x2000\_0000 to [0x2000\_0000+(SRAM\_size/2)-1]

This is illustrated in the following figure.

**Figure 3-26. SRAM blocks memory map**

For example, for a device containing 64 KB of SRAM the ranges are:

- SRAM\_L: 0x1FFF\_8000 – 0x1FFF\_FFFF
- SRAM\_U: 0x2000\_0000 – 0x2000\_7FFF

### 3.5.3.3 SRAM retention in low power modes

The SRAM is retained down to VLLS3 mode.

In VLLS2 the 16 KB region of SRAM\_U from 0x2000\_0000 is powered.

In VLLS1 no SRAM is retained; however, the [32-byte register file](#) is available.

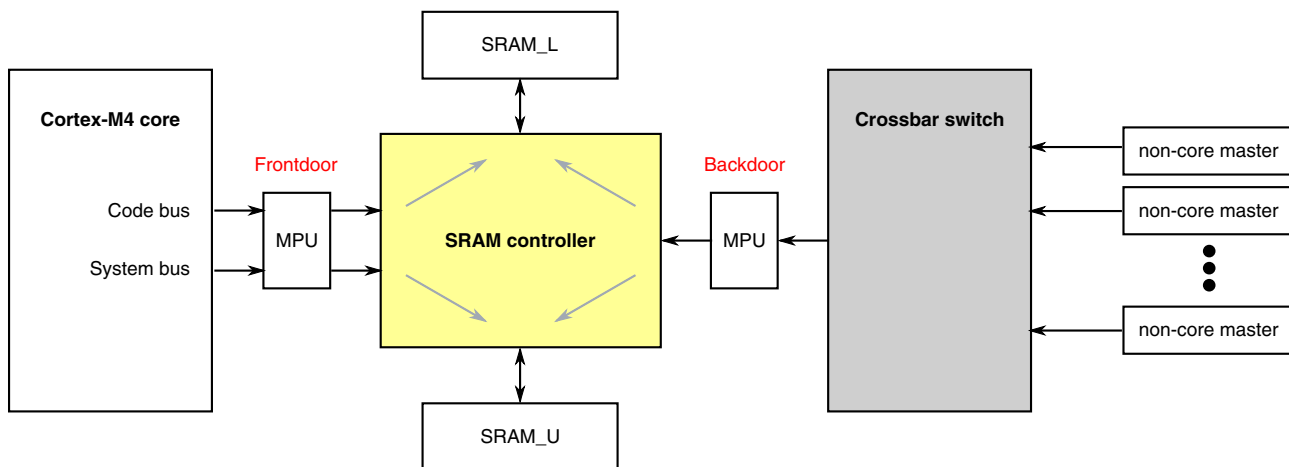

### 3.5.3.4 SRAM accesses

The SRAM is split into two logical arrays that are 32-bits wide.

- SRAM\_L — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- SRAM\_U — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA). There is one wait state added for non-core bus master accesses to the SRAM.

The following figure illustrates the SRAM accesses within the device.

**Figure 3-27. SRAM access diagram**

The following simultaneous accesses can be made to different logical regions of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

**NOTE**

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM\_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

**NOTE**

Burst-access cannot occur across the 0x2000\_0000 boundary that separates the two SRAM arrays. The two arrays should be treated as separate memory ranges for burst accesses.

**3.5.3.5 SRAM arbitration and priority control**

The MCM's SRAMAP register controls the arbitration and priority schemes for the two SRAM arrays.

**3.5.4 Local Memory Controller Configuration**

This section summarizes how the module has been configured in the chip.

**Figure 3-28. Local memory controller configuration**

**Table 3-41. Reference links to related information**

| Topic             | Related module          | Reference                               |
|-------------------|-------------------------|---|
| Full description  | Local memory controller | <a href="#">Local memory controller</a> |
| System memory map |                         | <a href="#">System memory map</a>       |
| Power management  |                         | <a href="#">Power management</a>        |

Table continues on the next page...

**Table 3-41. Reference links to related information (continued)**

| Topic     | Related module         | Reference                              |
|-----------|------------------------|--|
| Transfers | SRAM                   | <a href="#">SRAM</a>                   |
|           | ARM Cortex-M4 core     | <a href="#">ARM Cortex-M4 core</a>     |
|           | Memory protection unit | <a href="#">Memory protection unit</a> |

### 3.5.4.1 Local memory controller region assignment

The following table shows the LMEM's region mode register assignment for each region field. It also shows the available cache modes for each region.

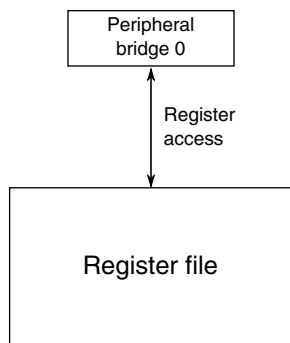

**Table 3-42. Cache regions**

| Address range           | Destination slave                         | Region number | Available cache modes                        |
|-------------------------|---|---------------|--|
| 0x0000_0000–0x07FF_FFFF | Program flash and read-only data          | R0            | Write-through and non-cacheable<br>1         |

| 0xD000_0000–0xDFFF_FFFF | FlexBus (External memory - Write-through) | R13           | Non-cacheable                                |
| 0xE000_0000–0xEFFF_FFFF | Private Peripheral Bus/Reserved           | R14           | Non-cacheable                                |
| 0xF000_0000–0xFFFF_FFFF | Reserved                                  | R15           | Non-cacheable                                |

1. Cache write hits do not write-through to program flash or FlexNVM regions because flash writes require flash programming.

### 3.5.5 System Register File Configuration

This section summarizes how the module has been configured in the chip.

**Figure 3-29. System Register file configuration**

**Table 3-43. Reference links to related information**

| Topic             | Related module | Reference                          |
|-------------------|----------------|------------------------------------|
| Full description  | Register file  | <a href="#">Register file</a>      |
| System memory map |                | <a href="#">System memory map</a>  |
| Clocking          |                | <a href="#">Clock distribution</a> |
| Power management  |                | <a href="#">Power management</a>   |

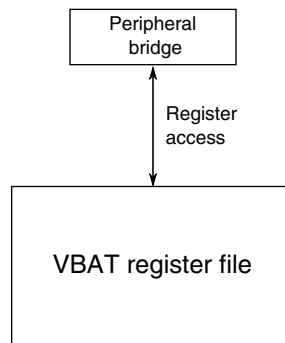

#### 3.5.5.1 System Register file

This device includes a 32-byte register file that is powered in all power modes.

Also, it retains contents during low-voltage detect (LVD) events and is only reset during a power-on reset.

### 3.5.6 VBAT Register File Configuration

This section summarizes how the module has been configured in the chip.

**Figure 3-30. VBAT Register file configuration**
**Table 3-44. Reference links to related information**

| Topic             | Related module     | Reference                          |
|-------------------|--------------------|------------------------------------|
| Full description  | VBAT register file | <a href="#">VBAT register file</a> |
| System memory map |                    | <a href="#">System memory map</a>  |
| Clocking          |                    | <a href="#">Clock distribution</a> |
| Power management  |                    | <a href="#">Power management</a>   |

### 3.5.6.1 VBAT register file

This device includes a 32-byte register file that is powered in all power modes and is powered by VBAT.

It is only reset during VBAT power-on reset.

### 3.5.7 EzPort Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-31. EzPort configuration**
**Table 3-45. Reference links to related information**

| Topic            | Related module | Reference              |
|------------------|----------------|------------------------|
| Full description | EzPort         | <a href="#">EzPort</a> |

*Table continues on the next page...*

**Table 3-45. Reference links to related information (continued)**

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|
| System memory map   |                 | <a href="#">System memory map</a>   |
| Clocking            |                 | <a href="#">Clock Distribution</a>  |
| Transfers           | Crossbar switch | <a href="#">Crossbar switch</a>     |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

### 3.5.7.1 JTAG instruction

The system JTAG controller implements an EZPORT instruction. When executing this instruction, the JTAG controller resets the core logic and asserts the EzPort chip select signal to force the processor into EzPort mode.

### 3.5.7.2 Flash Option Register (FOPT)

The FOPT[EZPORT\_DIS] bit can be used to prevent entry into EzPort mode during reset. If the FOPT[EZPORT\_DIS] bit is cleared, then the state of the chip select signal ( $\overline{\text{EZP\_CS}}$ ) is ignored and the MCU always boots in normal mode.

This option is useful for systems that use the  $\overline{\text{EZP\_CS}}$ /NMI signal configured for its NMI function. Disabling EzPort mode prevents possible unwanted entry into EzPort mode if the external circuit that drives the NMI signal asserts it during reset.

The FOPT register is loaded from the flash option byte. If the flash option byte is modified the new value takes effect for any subsequent resets, until the value is changed again.

## 3.5.8 FlexBus Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-32. FlexBus configuration**

**Table 3-46. Reference links to related information**

| Topic               | Related module               | Reference                                    |
|---------------------|------------------------------|--|
| Full description    | FlexBus                      | <a href="#">FlexBus</a>                      |
| System memory map   |                              | <a href="#">System memory map</a>            |
| Clocking            |                              | <a href="#">Clock distribution</a>           |
| Power management    |                              | <a href="#">Power management</a>             |
| Transfers           | Memory protection unit (MPU) | <a href="#">Memory protection unit (MPU)</a> |
| Signal multiplexing | Port control                 | <a href="#">Signal multiplexing</a>          |

### 3.5.8.1 FlexBus clocking

The system provides a dedicated clock source to the FlexBus module's external FB\_CLKOUT. Its clock frequency is derived from a divider of the MCGOUTCLK. See [Clock Distribution](#) for more details.

### 3.5.8.2 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the modules. The control signals are grouped as illustrated:

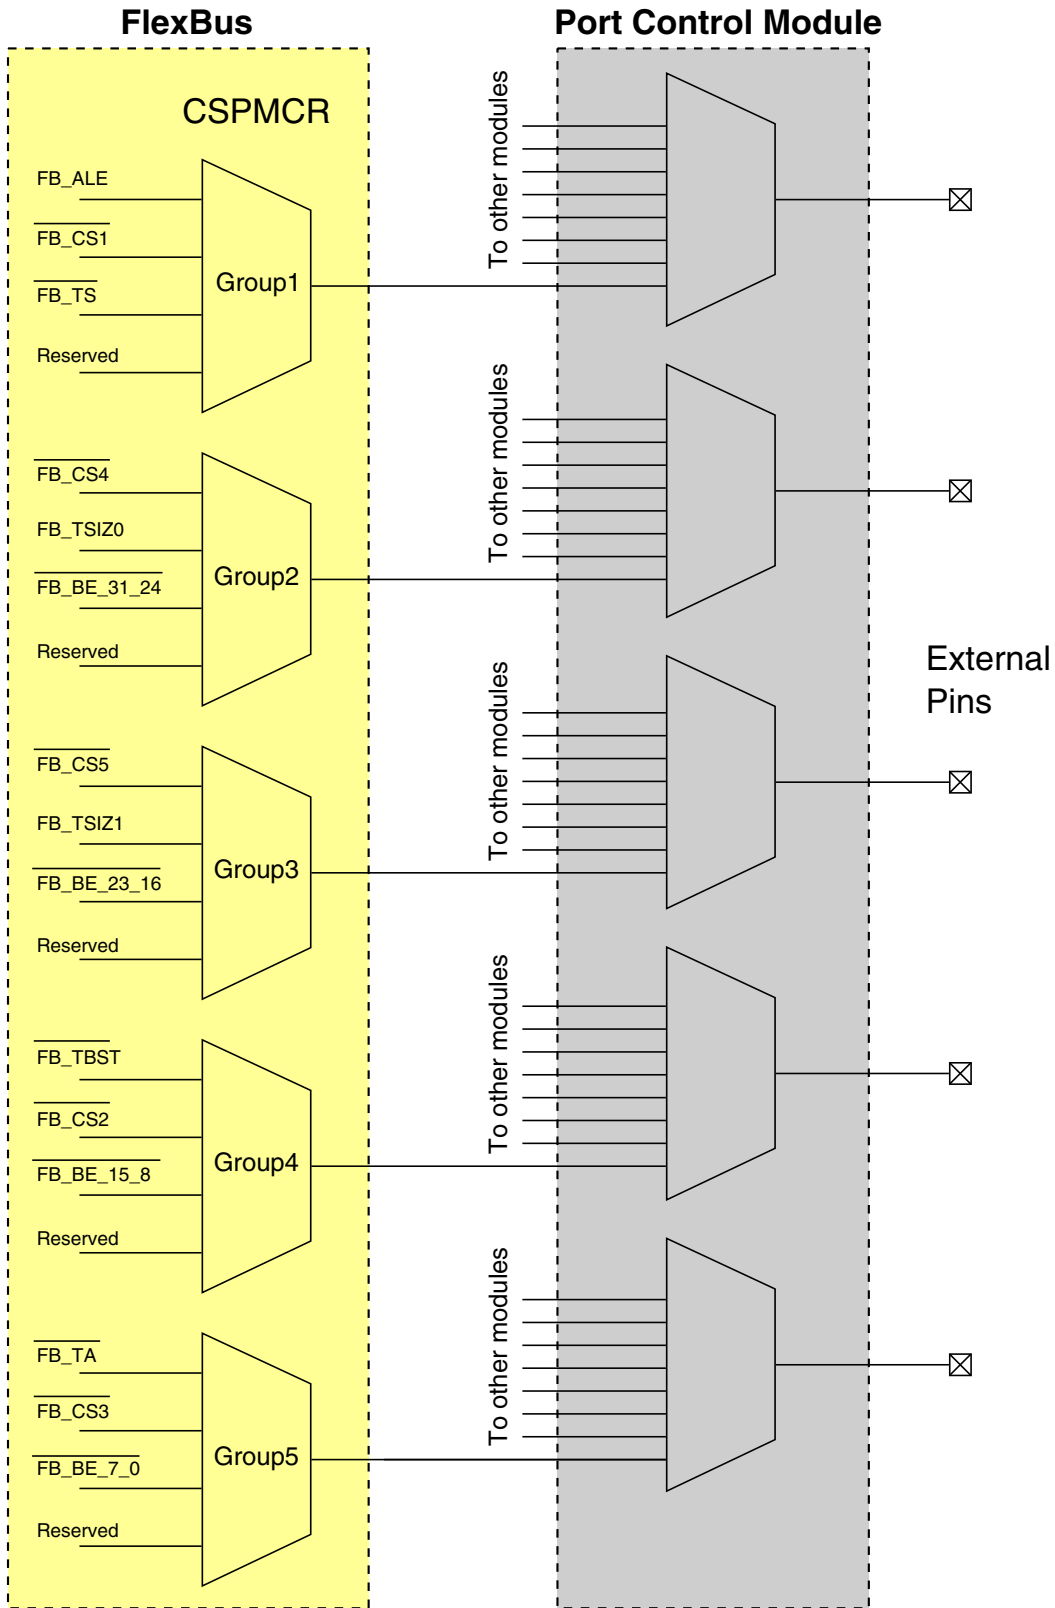

Figure 3-33. FlexBus control signal multiplexing

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin. All control signals, except for  $\overline{\text{FB\_TA}}$ , are assigned to the ALT5 function in the port control module. Since, unlike the other control signals,  $\overline{\text{FB\_TA}}$  is an input signal, it is assigned to the ALT6 function.

### 3.5.8.3 FlexBus CSCR0 reset value

On this device the CSCR0 resets to 0x003F\_FC00. Configure this register as needed before performing any FlexBus access.

### 3.5.8.4 FlexBus Security

When security is enabled on the device, FlexBus accesses may be restricted by configuring SIM\_SOPT2[FBSL]. See [System Integration Module \(SIM\)](#) for details.

### 3.5.8.5 FlexBus line transfers

Line transfers are not possible from the ARM Cortex-M4 core. Ignore any references to line transfers in the FlexBus chapter.

## 3.5.9 NAND Flash Controller (NFC) Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-34. NAND Flash Controller configuration**

**Table 3-47. Reference links to related information**

| Topic               | Related module              | Reference                           |
|---------------------|-----------------------------|-------------------------------------|
| Full description    | NAND Flash Controller (NFC) | <a href="#">NFC</a>                 |
| System memory map   |                             | <a href="#">System memory map</a>   |
| Clocking            |                             | <a href="#">Clock distribution</a>  |
| Power management    |                             | <a href="#">Power management</a>    |
| Signal multiplexing | Port control                | <a href="#">Signal multiplexing</a> |

### 3.5.9.1 NFC clock

The NFC clock frequency is determined by the selected NFC clock source and the `SIM_CLKDIV4[NFCDIV, NFCFRAC]` bitfields. See [NAND Flash Controller \(NFC\) clocking](#) for more details.

## 3.6 Security

### 3.6.1 CRC Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

Figure 3-35. CRC configuration

Table 3-48. Reference links to related information

| Topic             | Related module | Reference                         |

### 3.6.3 RNG Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

Figure 3-37. RNG configuration

Table 3-50. Reference links to related information

| Topic             | Related module | Reference                          |
|-------------------|----------------|------------------------------------|
| Full description  | RNG            | <a href="#">RNG</a>                |
| System memory map |                | <a href="#">System memory map</a>  |
| Clocking          |                | <a href="#">Clock distribution</a> |
| Power management  |                | <a href="#">Power management</a>   |

### 3.6.4 Drylce (tamper detect and secure storage) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

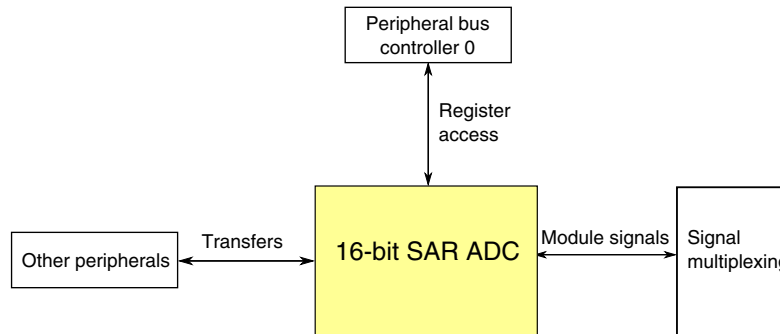

**NOTE**

The information on this module is available only under NDA. Please contact your local sales office for details.

## 3.7 Analog

### 3.7.1 16-bit SAR ADC with PGA Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-38. 16-bit SAR ADC with PGA configuration**

**Table 3-51. Reference links to related information**

| Topic               | Related module          | Reference                               |
|---------------------|-------------------------|---|
| Full description    | 16-bit SAR ADC with PGA | <a href="#">16-bit SAR ADC with PGA</a> |
| System memory map   |                         | <a href="#">System memory map</a>       |
| Clocking            |                         | <a href="#">Clock distribution</a>      |
| Power management    |                         | <a href="#">Power management</a>        |
| Signal multiplexing | Port control            | <a href="#">Signal multiplexing</a>     |

#### 3.7.1.1 ADC instantiation information

This device contains four ADCs. Each ADC contains a PGA channel for a total of four separate PGAs.

##### 3.7.1.1.1 Number of ADC channels

The number of ADC channels present on the device is determined by the pinout of the specific device package. For details regarding the number of ADC channel available on a particular package, refer to the signal multiplexing chapter of this MCU.

### 3.7.1.2 DMA Support on ADC

Applications may require continuous sampling of the ADC (4K samples/sec) that may have considerable load on the CPU. Though using PDB to trigger ADC may reduce some CPU load, the ADC supports DMA request functionality for higher performance when the ADC is sampled at a very high rate or cases where PDB is bypassed. The ADC can trigger the DMA (via DMA req) on conversion completion.

### 3.7.1.3 Connections/channel assignment

#### 3.7.1.3.1 ADC0 Connections/Channel Assignment

##### NOTE

As indicated by the following sections, each ADCx\_DP<sub>x</sub> input and certain ADCx\_DM<sub>x</sub> inputs may operate as single-ended ADC channels in single-ended mode.

##### 3.7.1.3.1.1 ADC0 Channel Assignment for 144-Pin Package

| ADC Channel (SC1n[ADCH]) | Channel | Input signal (SC1n[DIFF]= 1)       | Input signal (SC1n[DIFF]= 0) |

- This is the PMC bandgap 1V reference voltage not the VREF module 1.2 V reference voltage. Prior to reading from this ADC channel, ensure that you enable the bandgap buffer by setting the PMC\_REGSC[BGBE] bit. Refer to the device data sheet for the bandgap voltage ( $V_{BG}$ ) specification.

### 3.7.1.4 ADC1 Connections/Channel Assignment

#### NOTE

As indicated in the following tables, each ADCx\_DPx input and certain ADCx\_DMx inputs may operate as single-ended ADC channels in single-ended mode.

#### 3.7.1.4.1 ADC1 Channel Assignment for 144-Pin Package

| ADC Channel (SC1n[ADCH]) | Channel | Input signal (SC1n[DIFF]= 1)       | Input signal (SC1n[DIFF]= 0) |
|--------------------------|---------|------------------------------------|------------------------------|
| 00000                    | DAD0    | ADC1_DP0 and ADC1_DM0 <sup>1</sup> | ADC1_DP0 <sup>2</sup>        |

Table continues on the next page...

9. This is the PMC bandgap 1V reference voltage not the VREF module 1.2 V reference voltage. Prior to reading from this ADC channel, ensure that you enable the bandgap buffer by setting the PMC\_REGSC[BGBE] bit. Refer to the device data sheet for the bandgap voltage ( $V_{BG}$ ) specification.

### 3.7.1.5 ADC2 Connections/Channel Assignment

#### NOTE

As indicated by the above table, each ADCx\_DPx input and certain ADCx\_DMx inputs may operate as single-ended ADC channels in single-ended mode.

### 3.7.1.6 ADC3 Connections/Channel Assignment

#### NOTE

As indicated by the above table, each ADCx\_DPx input and certain ADCx\_DMx inputs may operate as single-ended ADC channels in single-ended mode.

### 3.7.1.7 ADC Channels MUX Selection

The following figure shows the assignment of ADCx\_SEn channels a and b through a MUX selection to ADC. To select between alternate set of channels, refer to ADCx\_CFG2[MUXSEL] bit settings for more details.

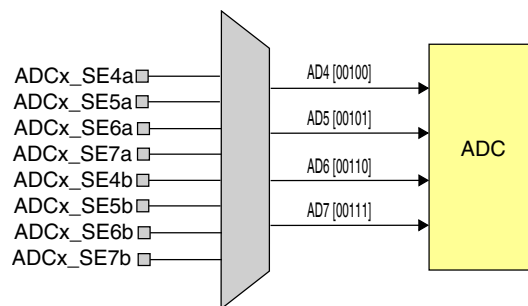

Figure 3-39. ADCx\_SEn channels a and b selection

### 3.7.1.8 ADC Hardware Interleaved Channels

The AD8 and AD9 channels on ADC<sub>x</sub> are interleaved in hardware using the following configuration.

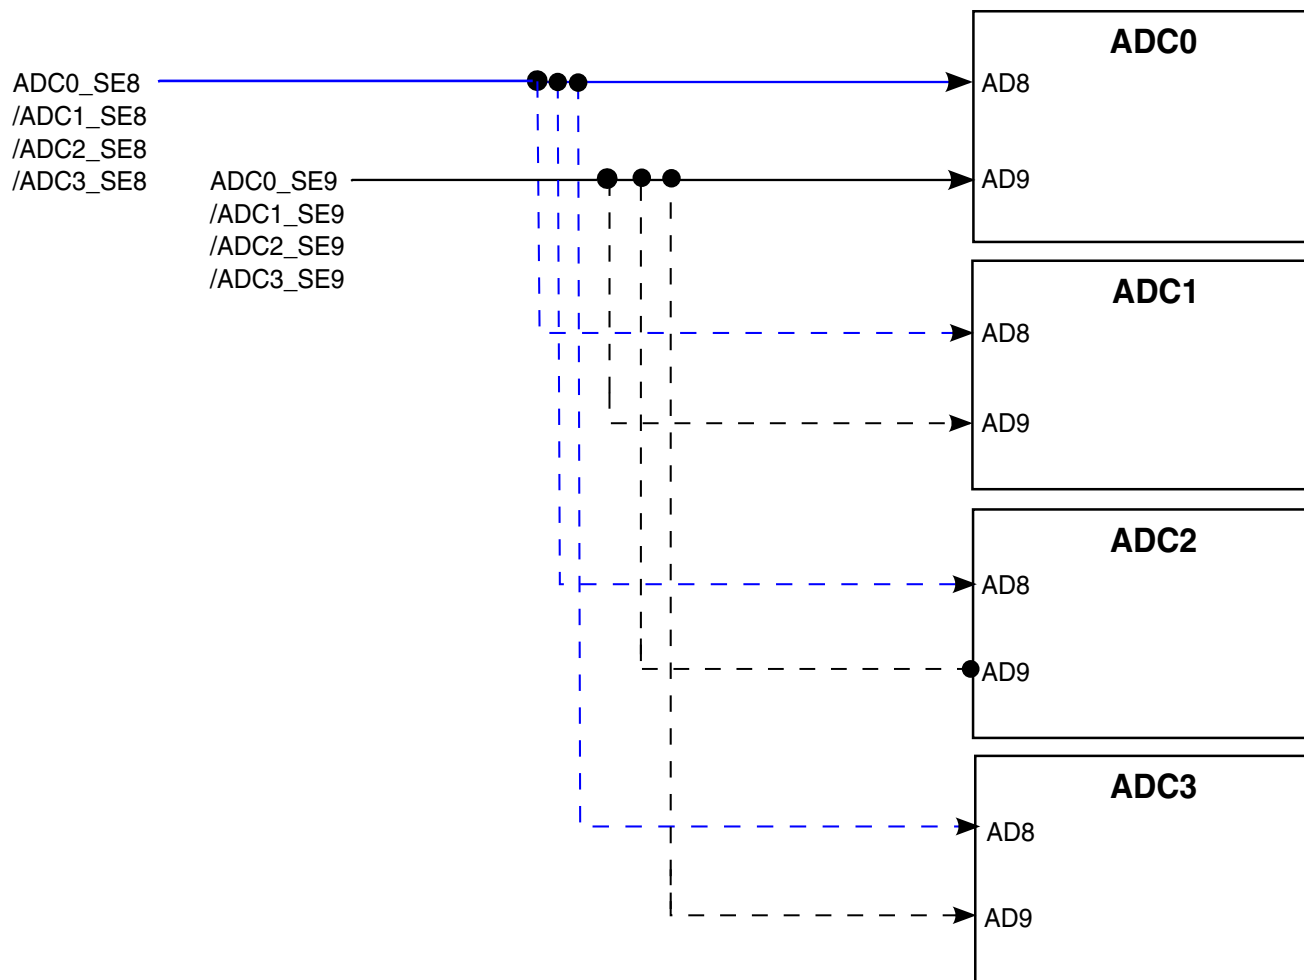

Figure 3-40. ADC hardware interleaved channels integration

### 3.7.1.9 ADC and PGA Reference Options

The ADC supports the following references:

- VREFH/VREFL - connected as the primary reference option
- 1.2 V VREF\_OUT - connected as the V<sub>ALT</sub> reference option

ADC<sub>x</sub>\_SC2[REFSEL] bit selects the voltage reference sources for ADC. Refer to REFSEL description in ADC chapter for more details.

The only reference option for the PGA is the 1.2 V VREF\_OUT source. The VREF\_OUT signal can either be driven by an external voltage source via the VREF\_OUT pin or from the output of the VREF module. Ensure that the VREF module is disabled when an external voltage source is used instead. For PGA maximum differential input signal swing range, refer to the device data sheet for 16-bit ADC with PGA characteristics.

### 3.7.1.10 ADC triggers

The ADC supports both software and hardware triggers. The primary hardware mechanism for triggering the ADC is the PDB. The PDB itself can be triggered by other peripherals. For example: RTC (Alarm, Seconds) signal is connected to the PDB. The PDB input trigger can receive the RTC (alarm/seconds) trigger forcing ADC conversions in run mode (where PDB is enabled). On the other hand, the ADC can conduct conversions in low power modes, not triggered by PDB. This allows the ADC to do conversions in low power mode and store the output in the result register. The ADC generates interrupt when the data is ready in the result register that wakes the system from low power mode. The PDB can also be bypassed by using the ADCxTRGSEL bits in the SIM\_SOPT7 register.

For operation of triggers in different modes, refer to Power Management chapter.

### 3.7.1.11 Alternate clock

For this device, the alternate clock is connected to OSC0ERCLK.

#### NOTE

This clock option is only usable when OSC0ERCLK is in the MHz range. A system with OSC0ERCLK in the kHz range has the optional clock source below minimum ADC clock operating frequency.

### 3.7.1.12 ADC low-power modes

This table shows the ADC low-power modes and the corresponding chip low-power modes.

**Table 3-52. ADC low-power modes**

| Module mode | Chip mode  |
|-------------|------------|
| Wait        | Wait, VLPW |

*Table continues on the next page...*

**Table 3-52. ADC low-power modes (continued)**

| Module mode    | Chip mode                |
|----------------|--------------------------|
| Normal Stop    | Stop, VLPS               |
| Low Power Stop | LLS, VLLS3, VLLS2, VLLS1 |

### 3.7.1.13 PGA Integration

- No additional external pins are required for the PGA as it is part of the ADC and is selected as a separate channel
- Each PGA connects to the differential ADC channels
- The PGA outputs differential pairs that are connected to ADC differential input
- When the PGA is used, differential input from the pins is connected to differential input channel 2 on ADCx

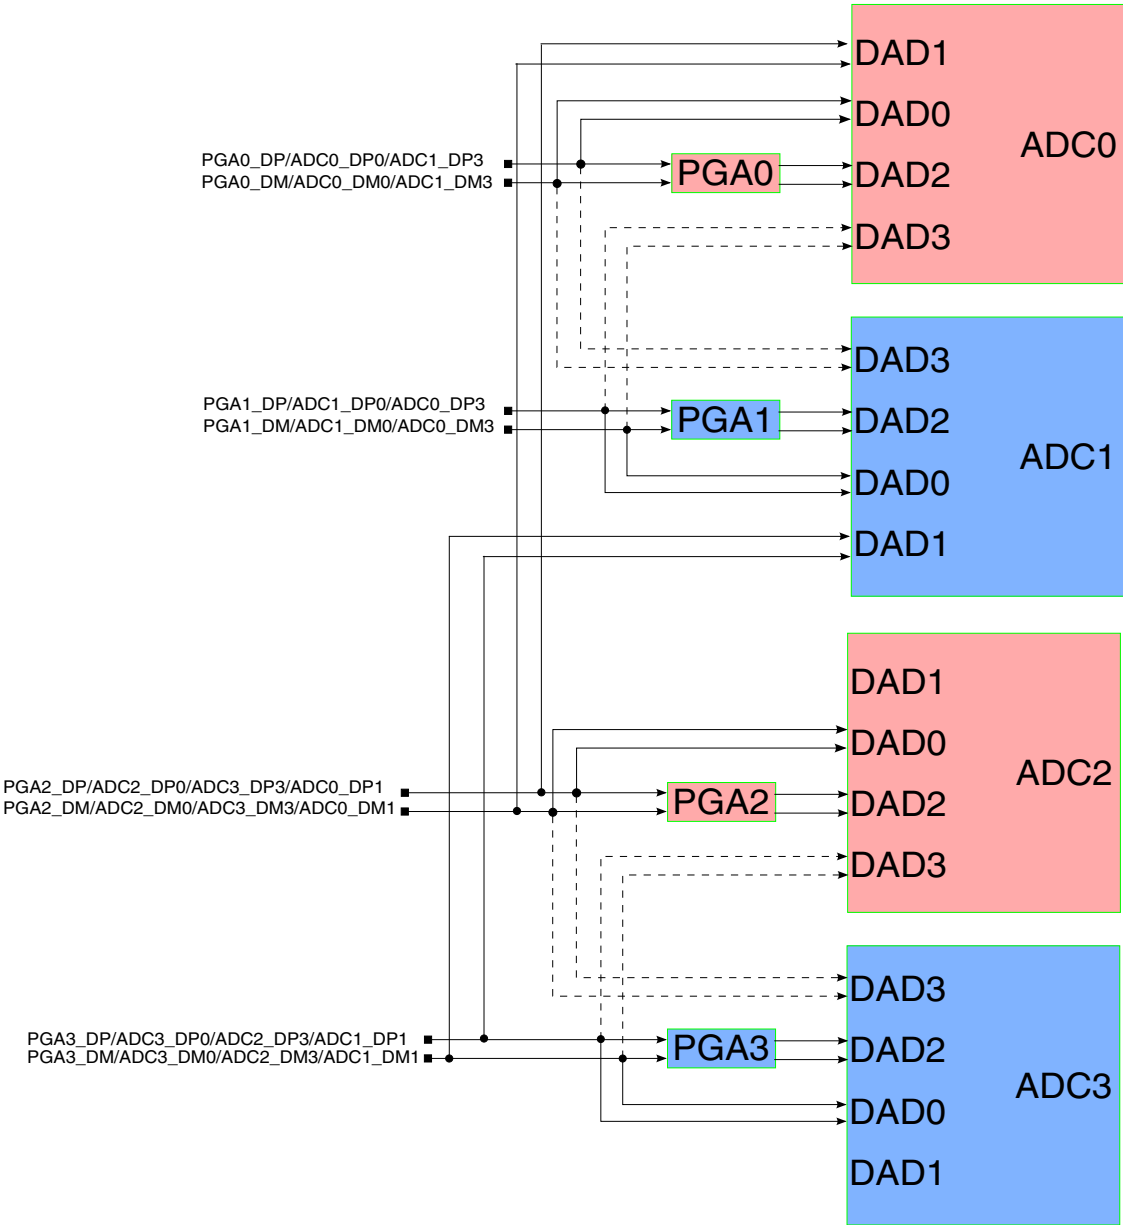

Figure 3-41. PGA Integration

### 3.7.2 CMP Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

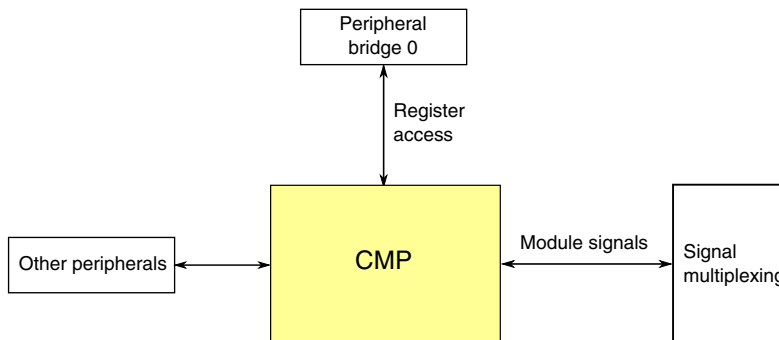

Figure 3-42. CMP configuration

Table 3-53. Reference links to related information

| Topic               | Related module   | Reference                           |

| IN5        | VREF Output/<br>CMP0_IN5 | VREF Output/<br>CMP1_IN5     | CMP2_IN5                     | CMP3_IN5                     |
| IN6        | Bandgap                  | Bandgap                      | Bandgap                      | Bandgap                      |
| IN7        | 6b DAC0 Reference        | 6b DAC1 Reference            | 6b DAC2 Reference            | 6b DAC3 Reference            |

### 3.7.2.2 CMP external references

The 6-bit DAC sub-block supports selection of two references. For this device, the references are connected as follows:

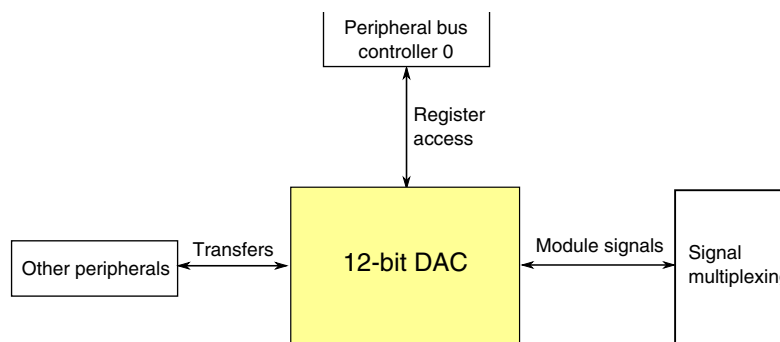

- VREF\_OUT -  $V_{in1}$  input
- VDD -  $V_{in2}$  input

### 3.7.2.3 External window/sample input

Individual PDB pulse-out signals control each CMP Sample/Window timing.

## 3.7.3 12-bit DAC Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-43. 12-bit DAC configuration**

**Table 3-55. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | 12-bit DAC     | <a href="#">12-bit DAC</a>          |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |

### 3.7.3.1 12-bit DAC Overview

This device contains two 12-bit digital-to-analog converters (DAC) with programmable reference generator output. The DAC includes a FIFO for DMA support.

### 3.7.3.2 12-bit DAC Output

The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

### 3.7.3.3 12-bit DAC Reference

For this device VREF\_OUT and VDDA are selectable as the DAC reference. VREF\_OUT is connected to the DACREF\_1 input and VDDA is connected to the DACREF\_2 input. Use DACx\_C0[DACRFS] control bit to select between these two options.

Be aware that if the DAC and ADC use the VREF\_OUT reference simultaneously, some degradation of ADC accuracy is to be expected due to DAC switching.

## 3.7.4 VREF Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

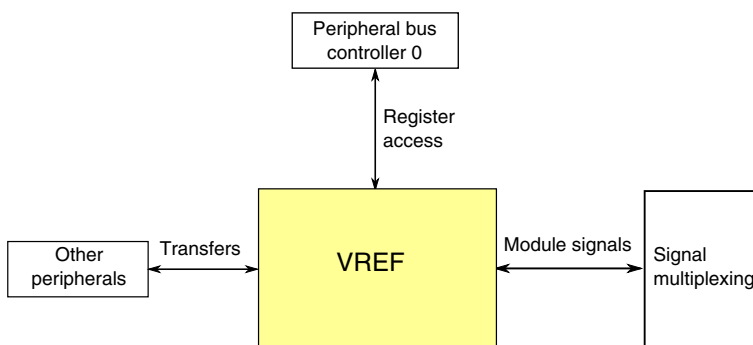

Figure 3-44. VREF configuration

Table 3-56. Reference links to related information

| Topic            | Related module | Reference            |
|------------------|----------------|----------------------|
| Full description | VREF           | <a href="#">VREF</a> |

Table continues on the next page...

**Table 3-56. Reference links to related information (continued)**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |

### 3.7.4.1 VREF Overview

This device includes a voltage reference (VREF) to supply an accurate 1.2 V voltage output.

The voltage reference can provide a reference voltage to external peripherals or a reference to analog peripherals, such as the ADC, DAC, or CMP.

#### NOTE

PMC\_REGSC[BGEN] bit must be set if the VREF regulator is required to remain operating in VLPx modes.

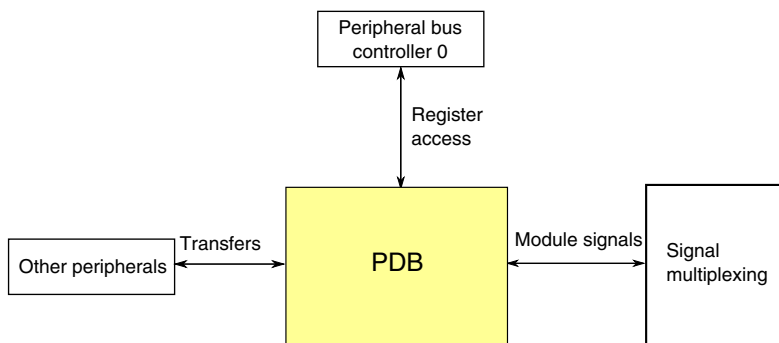

#### NOTE

For either an internal or external reference if the VREF\_OUT functionality is being used, VREF\_OUT signal must be connected to an output load capacitor. Refer the device data sheet for more details.

## 3.8 Timers

### 3.8.1 PDB Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-45. PDB configuration**

**Table 3-57. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | PDB            | <a href="#">PDB</a>                 |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |

### 3.8.1.1 PDB Instantiation

#### 3.8.1.1.1 PDB Output Triggers

**Table 3-58. PDB output triggers**

|  |   |
|--|---|
| Number of PDB channels for ADC trigger | 4 |
| Number of pre-triggers per PDB channel | 2 |
| Number of DAC triggers                 | 2 |
| Number of Pulse Out                    | 4 |

#### 3.8.1.1.2 PDB Input Trigger Connections

**Table 3-59. PDB Input Trigger Options**

| PDB Trigger | PDB Input        |
|-------------|------------------|
| 0000        | External Trigger |
| 0001        | CMP 0            |
| 0010        | CMP 1            |
| 0011        | CMP 2            |
| 0100        | PIT Ch 0 Output  |
| 0101        | PIT Ch 1 Output  |

*Table continues on the next page...*

**Table 3-59. PDB Input Trigger Options (continued)**

| PDB Trigger | PDB Input  |
|-------------|--|
| 0110        | PIT Ch 2 Output  |
| 0111        | PIT Ch 3 Output  |
| 1000        | FTM0 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG) |
| 1001        | FTM1 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG) |
| 1010        | FTM2 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG) |
| 1011        | FTM3 initialization trigger and channel triggers, as programmed in the FTM external trigger register (EXTTRIG) |
| 1100        | RTC Alarm  |
| 1101        | RTC Seconds  |
| 1110        | LPTMR Output   |
| 1111        | Software Trigger   |

### 3.8.1.2 PDB Module Interconnections

| PDB trigger outputs | Connection   |
|---------------------|--|
| Channel 0 triggers  | ADC0 trigger   |
| Channel 1 triggers  | ADC1 trigger and synchronous input 1 of FTM0   |
| Channel 2 triggers  | ADC2 trigger   |
| Channel 3 triggers  | ADC3 trigger and synchronous input 1 of FTM3   |
| DAC triggers        | DAC0 and DAC1 trigger  |
| Pulse-out           | Pulse-out connected to each CMP module's sample/window input to control sample operation |

### 3.8.1.3 Back-to-back acknowledgement connections

In this MCU, the following PDB back-to-back operation acknowledgment connections are implemented based on SIM\_MCR[PDBLOOP] bit setting.

When SIM\_MCR[PDBLOOP]=0:

- PDB channel 0 pre-trigger 0 acknowledgement input: ADC1SC1B\_COCO
- PDB channel 0 pre-trigger 1 acknowledgement input: ADC0SC1A\_COCO
- PDB channel 1 pre-trigger 0 acknowledgement input: ADC0SC1B\_COCO
- PDB channel 1 pre-trigger 1 acknowledgement input: ADC1SC1A\_COCO
- PDB channel 2 pre-trigger 0 acknowledgement input: ADC3SC1B\_COCO

- PDB channel 2 pre-trigger 1 acknowledgement input: ADC2SC1A\_COCO
- PDB channel 3 pre-trigger 0 acknowledgement input: ADC2SC1B\_COCO
- PDB channel 3 pre-trigger 1 acknowledgement input: ADC3SC1A\_COCO

**Figure 3-46. PDB back-to-back chain 1**

**Figure 3-47. PDB back-to-back chain 2**

When SIM\_MCR[PDBLOOP]=1:

- PDB channel 0 pre-trigger 0 acknowledgement input: ADC3SC1B\_COCO
- PDB channel 0 pre-trigger 1 acknowledgement input: ADC0SC1A\_COCO
- PDB channel 1 pre-trigger 0 acknowledgement input: ADC0SC1B\_COCO
- PDB channel 1 pre-trigger 1 acknowledgement input: ADC1SC1A\_COCO
- PDB channel 2 pre-trigger 0 acknowledgement input: ADC1SC1B\_COCO
- PDB channel 2 pre-trigger 1 acknowledgement input: ADC2SC1A\_COCO
- PDB channel 3 pre-trigger 0 acknowledgement input: ADC2SC1B\_COCO
- PDB channel 3 pre-trigger 1 acknowledgement input: ADC3SC1A\_COCO

**Figure 3-48. PDB back-to-back chain**

The application code can set the `PDBx_CHnC1[BB]` bits to configure the PDB pre-triggers as a single chain or several chains.

### 3.8.1.4 PDB Interval Trigger Connections to DAC

In this MCU, PDB interval trigger connections to DAC are implemented as follows.

- PDB interval trigger 0 connects to DAC0 hardware trigger input.
- PDB interval trigger 1 connects to DAC1 hardware trigger input.

### 3.8.1.5 DAC External Trigger Input Connections

In this MCU, the following DAC external trigger inputs are implemented.

- DAC external trigger input 1: `ADC1SC1A_COCO`

#### NOTE

Application code can set the `PDBx_DACINTCn[EXT]` bit to allow DAC external trigger input when the corresponding ADC Conversion complete flag, `ADCx_SC1n[COCO]`, is set.

### 3.8.1.6 Pulse-Out Connection

Individual PDB Pulse-Out signals are connected to each CMP block and used for sample window.

### 3.8.1.7 Pulse-Out Enable Register Implementation

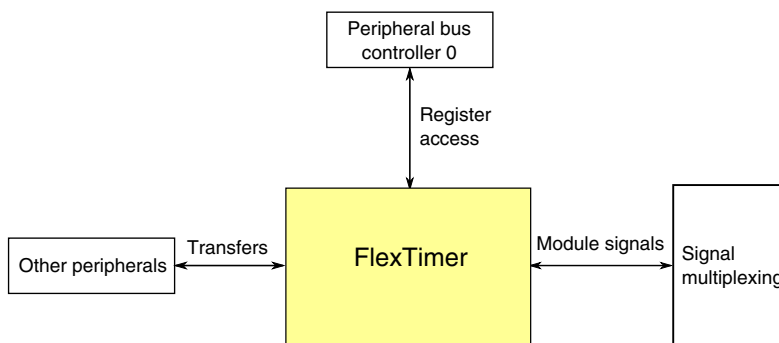

The following table shows the comparison of pulse-out enable register at the module and chip level.

**Table 3-60. PDB pulse-out enable register**

| Register | Module implementation         | Chip implementation   |
|----------|-------------------------------|---|
| POnEN    | 7:0 - POEN<br>31:8 - Reserved | 0 - POEN[0] for CMP0<br>1 - POEN[1] for CMP1<br>2 - POEN[2] for CMP2<br>3 - POEN[3] for CMP3<br>31:4 - Reserved |

## 3.8.2 FlexTimer Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-49. FlexTimer configuration**

**Table 3-61. Reference links to related information**

| Topic             | Related module | Reference                          |
|-------------------|----------------|------------------------------------|
| Full description  | FlexTimer      | <a href="#">FlexTimer</a>          |
| System memory map |                | <a href="#">System memory map</a>  |
| Clocking          |                | <a href="#">Clock distribution</a> |

Table continues on the next page...

**Table 3-61. Reference links to related information (continued)**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Power management    |                | <a href="#">Power management</a>    |
| Signal multiplexing | Port control   | <a href="#">Signal multiplexing</a> |

### 3.8.2.1 Instantiation Information

This device contains four FlexTimer modules.

The following table shows how these modules are configured.

**Table 3-62. FTM Instantiations**

| FTM instance | Number of channels | Features/usage                                     |
|--------------|--------------------|--|
| FTM0         | 8                  | 3-phase motor + 2 general purpose or stepper motor |
| FTM1         | 2 <sup>1</sup>     | Quadrature decoder or general purpose              |
| FTM2         | 2 <sup>1</sup>     | Quadrature decoder or general purpose              |
| FTM3         | 8                  | 3-phase motor + 2 general purpose or stepper motor |

1. Only channels 0 and 1 are available.

Compared with the FTM0 and FTM3 configuration, the FTM1 and FTM2 configuration adds the Quadrature decoder feature and reduces the number of channels.

### 3.8.2.2 External Clock Options

By default each FTM is clocked by the internal bus clock (the FTM refers to it as system clock). Each module contains a register setting that allows the module to be clocked from an external clock instead. There are two external FTM\_CLKINx pins that can be selected by any FTM module via the SIM\_SOPT4 register.

### 3.8.2.3 Fixed frequency clock

The fixed frequency clock for each FTM is MCGFFCLK.

### 3.8.2.4 FTM Interrupts

The FlexTimer has multiple sources of interrupt. However, these sources are OR'd together to generate a single interrupt request per FTM module to the interrupt controller. When an FTM interrupt occurs, read the FTM status registers (FMS, SC, and STATUS) to determine the exact interrupt source.

### 3.8.2.5 FTM Fault Detection Inputs

The following fault detection input options for the FTM modules are selected via the SIM\_SOPT4 register. The external pin option is selected by default.

- FTM0 FAULT0 = FTM0\_FLT0 pin or CMP0 output
- FTM0 FAULT1 = FTM0\_FLT1 pin or CMP1 output
- FTM0 FAULT2 = FTM0\_FLT2 pin or CMP2 output
- FTM0 FAULT3 = FTM0\_FLT3 pin
  
- FTM1 FAULT0 = FTM1\_FLT0 pin or CMP0 output
- FTM1 FAULT1 = CMP1 output
- FTM1 FAULT2 = CMP2 output
  
- FTM2 FAULT0 = FTM2\_FLT0 pin or CMP0 output
- FTM2 FAULT1 = CMP1 output
- FTM2 FAULT2 = CMP2 output
  
- FTM3 FAULT0 = FTM3\_FLT0 pin or CMP0 output
- FTM3 FAULT1 = CMP2 output
- FTM3 FAULT2 = CMP3 output

### 3.8.2.6 FTM Hardware Triggers

The FTM synchronization hardware triggers are connected in the chip as follows:

- FTM0 hardware trigger 0 = CMP0 Output or FTM1 Match (when enabled in the FTM1 External Trigger (EXTTRIG) register)
- FTM0 hardware trigger 1 = PDB channel 1 Trigger Output or FTM2 Match (when enabled in the FTM2 External Trigger (EXTTRIG) register)
- FTM0 hardware trigger 2 = FTM0\_FLT0 pin
  
- FTM1 hardware trigger 0 = CMP0 Output
- FTM1 hardware trigger 1 = CMP1 Output
- FTM1 hardware trigger 2 = FTM1\_FLT0 pin

- FTM2 hardware trigger 0 = CMP0 Output
- FTM2 hardware trigger 1 = CMP2 Output
- FTM2 hardware trigger 2 = FTM2\_FLT0 pin
  
- FTM3 hardware trigger 0 = CMP3 Output or FTM1 Match (when enabled in the FTM1 External Trigger (EXTTRIG) register)
- FTM3 hardware trigger 1 = PDB channel 3 Trigger Output or FTM2 Match (when enabled in the FTM2 External Trigger (EXTTRIG) register)
- FTM3 hardware trigger 2 = FTM3\_FLT0 pin

For the triggers with more than one option, SIM\_SOPT4 controls the selection.

### 3.8.2.7 Input capture options for FTM module instances

The following channel 0 input capture source options are selected via SIM\_SOPT4. The external pin option is selected by default.

- FTM1 channel 0 input capture = FTM1\_CH0 pin or CMP0 output or CMP1 output or USB start of frame pulse
- FTM2 channel 0 input capture = FTM2\_CH0 pin or CMP0 output or CMP1 output

#### NOTE

When the USB start of frame pulse option is selected as an FTM channel input capture, disable the USB SOF token interrupt in the USB Interrupt Enable register (INTEN[SOFTOKEN]) to avoid USB enumeration conflicts.

### 3.8.2.8 FTM output triggers for other modules

FTM output triggers can be selected as input triggers for the PDB and ADC modules. See [PDB Instantiation](#) and [ADC triggers](#).

### 3.8.2.9 FTM Global Time Base

This chip provides the optional FTM global time base feature (see [Global time base \(GTB\)](#)).

FTM0 provides the only source for the FTM global time base. The other FTM modules can share the time base as shown in the following figure:

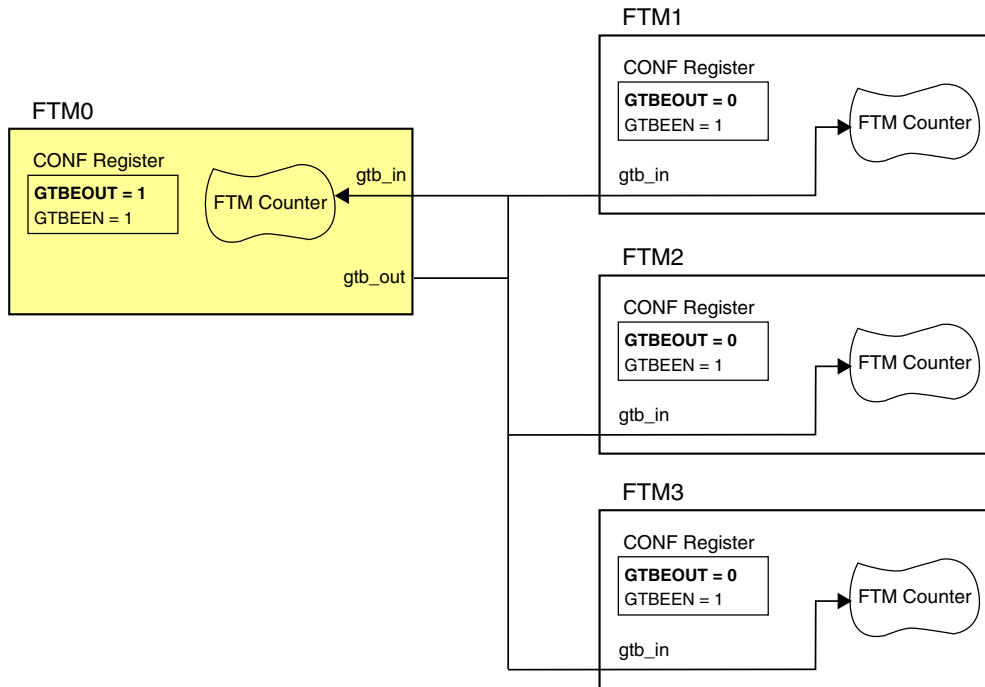

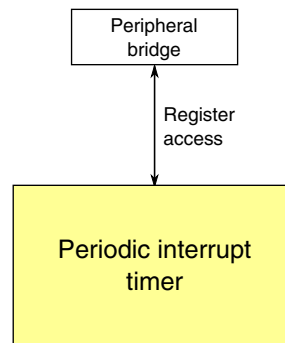

Figure 3-50. FTM Global Time Base Configuration

### 3.8.2.10 FTM BDM and debug halt mode

In the FTM chapter, references to the chip being in "BDM" are the same as the chip being in "debug halt mode".

### 3.8.3 PIT Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-51. PIT configuration**
**Table 3-63. Reference links to related information**

| Topic             | Related module | Reference                          |
|-------------------|----------------|------------------------------------|
| Full description  | PIT            | <a href="#">PIT</a>                |
| System memory map |                | <a href="#">System memory map</a>  |
| Clocking          |                | <a href="#">Clock Distribution</a> |
| Power management  |                | <a href="#">Power management</a>   |

### 3.8.3.1 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below.

**Table 3-64. PIT channel assignments for periodic DMA triggering**

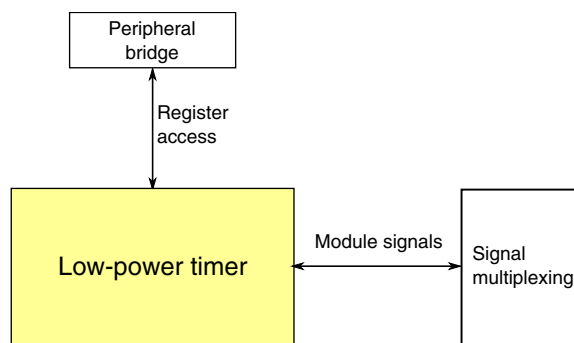

| DMA Channel Number | PIT Channel   |
|--------------------|---------------|
| DMA Channel 0      | PIT Channel 0 |
| DMA Channel 1      | PIT Channel 1 |
| DMA Channel 2      | PIT Channel 2 |
| DMA Channel 3      | PIT Channel 3 |

### 3.8.3.2 PIT/ADC Triggers

PIT triggers are selected as ADCx trigger sources using the `SIM_SOPT7[ADCxTRGSEL]` fields. For more details, refer to SIM chapter.

## 3.8.4 Low-power timer configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-52. LPTMR configuration**

**Table 3-65. Reference links to related information**

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|
| Full description    | Low-power timer | <a href="#">Low-power timer</a>     |
| System memory map   |                 | <a href="#">System memory map</a>   |
| Clocking            |                 | <a href="#">Clock Distribution</a>  |
| Power management    |                 | <a href="#">Power management</a>    |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

### 3.8.4.1 LPTMR prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMR0\_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

#### NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

| LPTMR0_PSR[PCS] | Prescaler/glitch filter clock number | Chip clock   |
|-----------------|--------------------------------------|--|
| 00              | 0                                    | MCGIRCLK — internal reference clock (not available in VLPS/LLS/VLLS modes) |
| 01              | 1                                    | LPO — 1 kHz clock  |
| 10              | 2                                    | ERCLK32K — secondary external reference clock                              |
| 11              | 3                                    | OSC0ERCLK — external reference clock                                       |

See [Clock Distribution](#) for more details on these clocks.

### 3.8.4.2 LPTMR pulse counter input options

The LPTMR\_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following table shows the chip-specific input assignments for this bitfield.

| LPTMR_CSR[TPS] | Pulse counter input number | Chip input     |
|----------------|----------------------------|----------------|
| 00             | 0                          | CMP0 output    |
| 01             | 1                          | LPTMR_ALT1 pin |
| 10             | 2                          | LPTMR_ALT2 pin |
| 11             | 3                          | Reserved       |

### 3.8.5 CMT Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

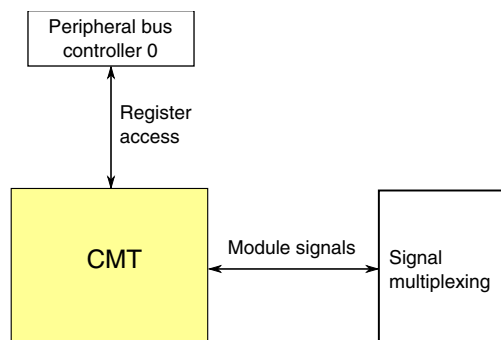

Figure 3-53. CMT configuration

Table 3-66. Reference links to related information

| Topic               | Related module                      | Reference                           |
|---------------------|-------------------------------------|-------------------------------------|
| Full description    | Carrier modulator transmitter (CMT) | <a href="#">CMT</a>                 |
| System memory map   |                                     | <a href="#">System memory map</a>   |
| Clocking            |                                     | <a href="#">Clock distribution</a>  |
| Power management    |                                     | <a href="#">Power management</a>    |
| Signal multiplexing | Port control                        | <a href="#">Signal multiplexing</a> |

#### 3.8.5.1 Instantiation Information

This device contains one CMT module.

### 3.8.5.2 IRO Drive Strength

The IRO pad requires higher current drive than can be obtained from a single pad. For this device, the pin associated with the CMT\_IRO signal is doubled bonded to two pads.

SIM\_SOPT2[CMTUARTPAD] can be used to configure the pin associated with the CMT\_IRO signal as a higher current output port pin.

### 3.8.6 RTC configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

Figure 3-54. RTC configuration

Table 3-67. Reference links to related information

| Topic             | Related module | Reference                          |
|-------------------|----------------|------------------------------------|
| Full description  | RTC            | <a href="#">RTC</a>                |
| System memory map |                | <a href="#">System memory map</a>  |
| Clocking          |                | <a href="#">Clock Distribution</a> |
| Power management  |                | <a href="#">Power management</a>   |

#### 3.8.6.1 RTC\_CLKOUT signal

When the RTC is enabled and the port control module selects the RTC\_CLKOUT function, the RTC\_CLKOUT signal outputs a 1 Hz or 32 kHz output derived from RTC oscillator as shown below.

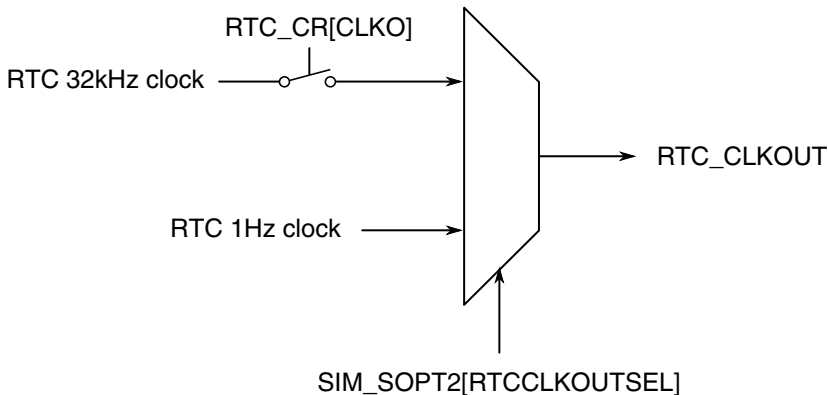

Figure 3-55. RTC\_CLKOUT generation

### 3.9 Communication interfaces

#### 3.9.1 Ethernet Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

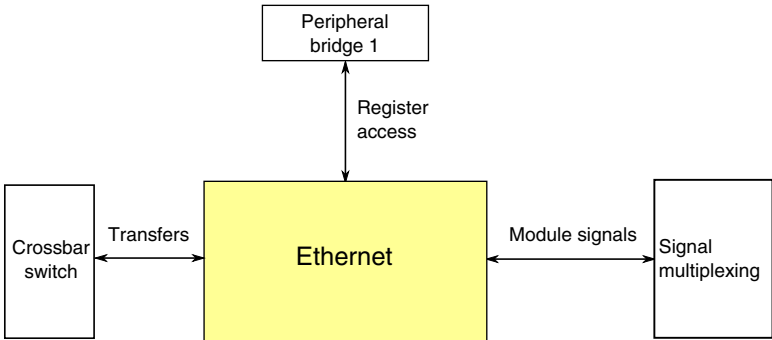

Figure 3-56. Ethernet configuration

Table 3-68. Reference links to related information

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|
| Full description    | Ethernet        | <a href="#">Ethernet</a>            |
| System memory map   |                 | <a href="#">System memory map</a>   |
| Clocking            |                 | <a href="#">Clock Distribution</a>  |
| Transfers           | Crossbar switch | <a href="#">Crossbar switch</a>     |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

### 3.9.1.1 Ethernet Clocking Options

The Ethernet module uses the following clocks:

- The device's system clock is connected to the module clock, as named in the [Ethernet chapter](#). The minimum system clock frequency for 100 Mbps operation is 25 MHz.
- An externally-supplied 25 MHz MII clock or 50 MHz RMII clock. This clock is used as the timing reference for the external MII or RMII interface.
- A time-stamping clock for the IEEE 1588 timers.

For more details on the Ethernet module clocking options, see [Ethernet Clocking](#).

### 3.9.1.2 RMII Clocking

On this device, RMII\_REF\_CLK is internally tied to EXTAL. See [Clock Distribution](#) for clocking requirements.

### 3.9.1.3 IEEE 1588 Timers

The ethernet module includes a four channel timer module for IEEE 1588 timestamping. The timer supports input capture (rising, falling, or both edges), output compare (toggle or pulse with programmable polarity). The timer matches on greater than or equal (the 1588 can skip numbers, so the counter might not ever exactly match the compare value).

The counter is able to operate asynchronously to the ethernet bus by using one of four clock sources. See [Ethernet Clocking](#) for more details.

### 3.9.1.4 Ethernet Operation in Low Power Modes

The Ethernet module is not fully operational in any low power modes. However, the module does support magic packet detection that can generate a wakeup in stop mode if enabled.

During low power operation:

- The MAC transmit logic is disabled
- The core FIFO receive/transmit functions are disabled
- The MAC receive logic is kept in normal mode, but it ignores all traffic from the line except magic packets.

The receive logic needed for magic packet detection is clocked using the externally-supplied MII or RMII clock. This allows for the wakeup functionality in stop mode. No Ethernet operation, including magic packet wakeup, is supported in VLPx modes.

### 3.9.1.4.1 IEEE 1588 Timer Operation in Low Power Modes

The 1588 counter and 1588 timer channels can continue operating in low power modes provided their clock is enabled in that mode.

The 1588 timer channels can also generate an interrupt to exit the low power mode if the clock is enabled in that mode.

### 3.9.1.5 Ethernet Doze Mode

The doze mode for the Ethernet module is the same as the wait and VLPW modes for the chip.

### 3.9.1.6 Ethernet Interrupts

The Ethernet has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate an interrupt request. See below for a summary:

| Interrupt request                 | Interrupt source   |
|-----------------------------------|--|
| IEEE 1588 timer interrupt         | <ul style="list-style-type: none"> <li>• Periodic timer overflow</li> <li>• Time stamp available</li> <li>• 1588 timer interrupt</li> </ul>  |
| Transmit interrupt                | <ul style="list-style-type: none"> <li>• Transmit frame interrupt</li> <li>• Transmit buffer interrupt</li> </ul>  |
| Receive interrupt                 | <ul style="list-style-type: none"> <li>• Receive frame interrupt</li> <li>• Receive buffer interrupt</li> </ul>  |
| Error and miscellaneous interrupt | <ul style="list-style-type: none"> <li>• Wake-up</li> <li>• Payload receive error</li> <li>• Babbling receive error</li> <li>• Babbling transmit error</li> <li>• Graceful stop complete</li> <li>• MII interrupt – Data transfer done</li> <li>• Ethernet bus error</li> <li>• Late collision</li> <li>• Collision retry limit</li> </ul> |

### 3.9.1.7 Ethernet event signal

The event signal output is not supported on this device. Therefore, ATCR[PINPER] has no effect.

### 3.9.2 Universal Serial Bus (USB) FS Subsystem

The USB FS subsystem includes these components:

- Dual-role USB OTG-capable (On-The-Go) controller that supports a full-speed (FS) device or FS/LS host. The module complies with the USB 2.0 specification.
- USB transceiver that includes internal 15 kΩ pulldowns on the D+ and D- lines for host mode functionality.
- A 3.3 V regulator.
- USB device charger detection module.
- VBUS detect signal: To detect a valid VBUS in device mode, use a GPIO signal that can wake the chip in all power modes. See [VBUS detect](#).

**Figure 3-57. USB FS/LS Subsystem Overview**

#### NOTE

Use the following code sequence to select USB clock source, USB clock divide ratio, and enable its clock gate to avoid potential clock glitches which may result in USB enumeration stage failure.

1. Select the USB clock source by configuring SIM\_SOPT2.
2. Select the desired clock divide ratio by configuring SIM\_CLKDIV2.
3. Enable USB clock gate by setting SIM\_SCGC4.

### 3.9.2.1 USB Wakeup

When the USB detects that there is no activity on the USB bus for more than 3 ms, the INT\_STAT[SLEEP] bit is set. This bit can cause an interrupt and software decides the appropriate action.

Waking from a low power mode (except in LLS/VLLS mode where USB is not powered) occurs through an asynchronous interrupt triggered by activity on the USB bus. Setting the USBTRC0[USBRESMEN] bit enables this function.

### 3.9.2.2 USB Power Distribution

This chip includes an internal 5 V to 3.3 V USB regulator that powers the USB transceiver or the MCU (depending on the application).

#### NOTE

In the following examples, VREGIN is used instead of VREG\_IN0. Similarly, VOUT33 is used instead of VREGOUT. Please refer to the [Signal multiplexing and signal description section](#) for details on signals for this device.

#### 3.9.2.2.1 AA/AAA cells power supply

The chip can be powered by two AA/AAA cells. In this case, the MCU is powered through VDD which is within the 1.8 to 3.0 V range. After USB cable insertion is detected, the USB regulator is enabled to power the USB transceiver.

Figure 3-58. USB regulator AA cell usecase

### 3.9.2.2.2 Li-Ion battery power supply

The chip can also be powered by a single Li-ion battery. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU. When connected to a USB host, the input source of this regulator is switched to the USB bus supply from the Li-ion battery. To charge the battery, the MCU can configure the battery charger according to the charger detection information.

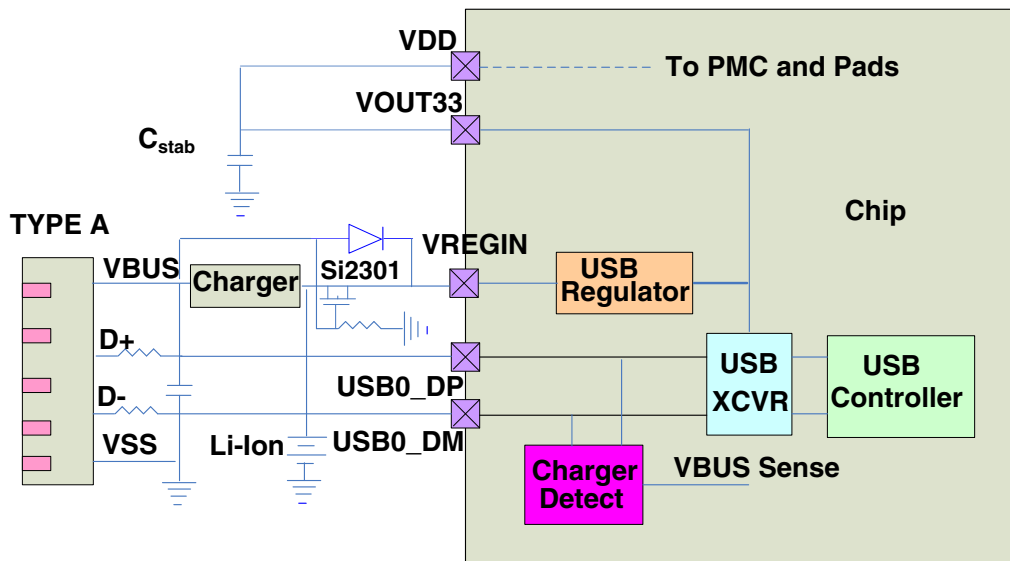

Figure 3-59. USB regulator Li-ion usecase

### 3.9.2.2.3 USB bus power supply

The chip can also be powered by the USB bus directly. In this case, VOUT33 is connected to VDD. The USB regulator must be enabled by default to power the MCU, then to power USB transceiver or external sensor.

Figure 3-60. USB regulator bus supply

### 3.9.2.3 USB power management

The regulator should be put into STANDBY mode whenever the chip is in Stop mode.

### 3.9.2.4 VBUS detect

The USB FS controller does not include a dedicated VBUS detect pin. However, a GPIO pin with interrupt capability can be used to detect the presence of VBUS in device mode. If a GPIO pin with LLWU capability is used, VBUS can be detected in all low power modes, including LLS and VLLS.

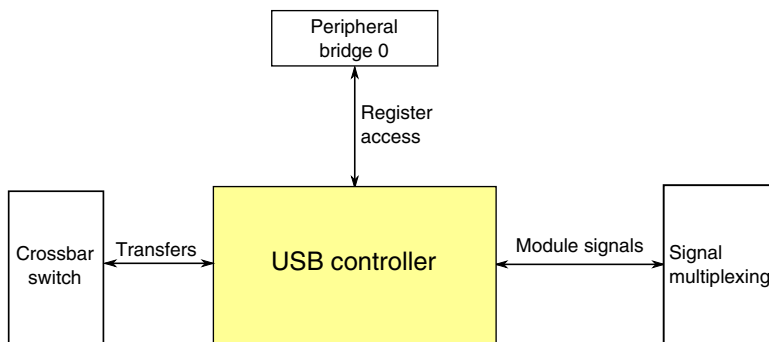

Software is responsible for detecting VBUS via a GPIO pin and configuring the USB controller appropriately in response to the rising or falling edge of VBUS.

**NOTE**

An appropriately sized resistive voltage divider must be used if the GPIO pin does not directly support a 5V input.

### 3.9.2.5 USB controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-61. USB controller configuration**

**Table 3-69. Reference links to related information**

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|
| Full description    | USB controller  | <a href="#">USB controller</a>      |
| System memory map   |                 | <a href="#">System memory map</a>   |
| Clocking            |                 | <a href="#">Clock Distribution</a>  |
| Transfers           | Crossbar switch | <a href="#">Crossbar switch</a>     |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

**NOTE**

When USB is not used in the application, it is recommended that the USB regulator VREGIN and VOUT33 pins remain floating.

**NOTE**

When USB is not used in the application, it is recommended that the remain floating.

### 3.9.2.6 USB DCD Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-62. USB DCD configuration**

**Table 3-70. Reference links to related information**

| Topic             | Related module       | Reference                            |
|-------------------|----------------------|--------------------------------------|
| Full description  | USB DCD              | <a href="#">USB DCD</a>              |
| System memory map |                      | <a href="#">System memory map</a>    |
| Clocking          |                      | <a href="#">Clock Distribution</a>   |
|                   | USB FS/LS controller | <a href="#">USB FS/LS controller</a> |

### 3.9.2.7 USB Voltage Regulator Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-63. USB Voltage Regulator configuration**

**Table 3-71. Reference links to related information**

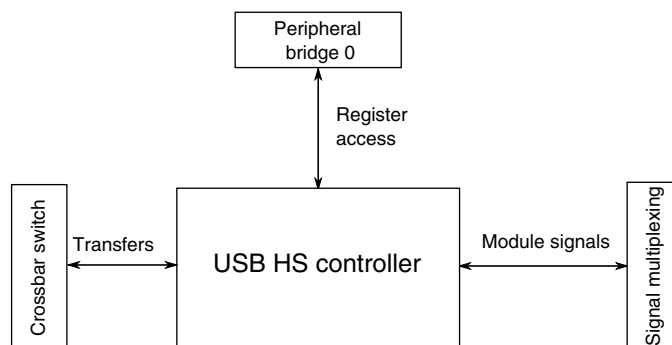

| Topic               | Related module        | Reference                             |
|---------------------|-----------------------|---------------------------------------|
| Full description    | USB Voltage Regulator | <a href="#">USB Voltage Regulator</a> |

| Transfers           | Crossbar switch | <a href="#">Crossbar switch</a>     |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

### 3.9.3.1 ULPI interface

To operate the USB HS OTG controller, connect the USB HS controller to an external ULPI PHY/transceiver via the ULPI interface.

The following figure illustrates the connection of the ULPI transceiver. The ULPI transceiver is an implementation of the HS/FS/LS physical layer which encapsulates the 60+ pin UTMI+ interface using a 12-pin digital interface.

The board-level implementation of a ULPI-based product is dependent on the PHY vendor. The ULPI PHY manages USB clocking, DP/DM bias resistors, and the OTG VBUS charge pump. For OTG applications requiring full host power (100 – 500 mA downstream current), an additional USB power-switch chip may be used. This OTG configuration may be used as a USB device, host, or dual-role device under firmware control.

**Figure 3-65. USB HS OTG module and ULPI PHY**

### 3.9.4 CAN Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

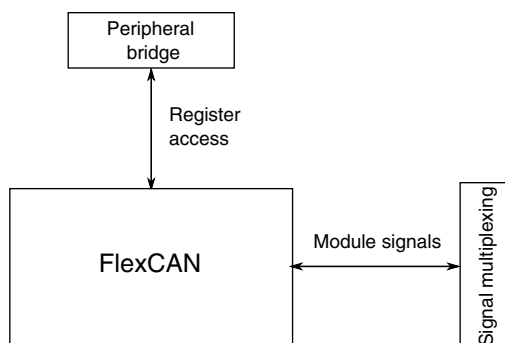

Figure 3-66. CAN configuration

Table 3-73. Reference links to related information

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | CAN            | <a href="#">CAN</a>                 |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock Distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal Multiplexing | Port control   | <a href="#">Signal Multiplexing</a> |

#### 3.9.4.1 Number of FlexCAN modules

This device contains 2 identical FlexCAN modules.

#### 3.9.4.2 Reset value of MDIS bit

The CAN\_MCR[MDIS] bit is set after reset. Therefore, FlexCAN module is disabled following a reset.

#### 3.9.4.3 Number of message buffers

Each FlexCAN module contains 16 message buffers. Each message buffer is 16 bytes.

### 3.9.4.4 FlexCAN Clocking

#### 3.9.4.4.1 Clocking Options

CAN\_CTRL1[CLKSRC] register bit selects between clocking the FlexCAN from the internal bus clock or the input clock (OSCERCLK). In this case, a clock source with PLL FM jitter must not be used.

#### 3.9.4.4.2 Clock Gating

The clock to each CAN module can be gated on and off using the SCGC<sub>n</sub>[CAN<sub>x</sub>] bits. These bits are cleared after any reset, which disables the clock to the corresponding module. The appropriate clock enable bit should be set by software at the beginning of the FlexCAN initialization routine to enable the module clock before attempting to initialize any of the FlexCAN registers.

### 3.9.4.5 FlexCAN Interrupts

The FlexCAN has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

| Request          | Sources   |
|------------------|---|
| Message buffer   | Message buffers 0-15  |
| Bus off          | Bus off   |
| Error            | <ul style="list-style-type: none"> <li>• Bit1 error</li> <li>• Bit0 error</li> <li>• Acknowledge error</li> <li>• Cyclic redundancy check (CRC) error</li> <li>• Form error</li> <li>• Stuffing error</li> <li>• Transmit error warning</li> <li>• Receive error warning</li> </ul> |
| Transmit Warning | Transmit Warning  |
| Receive Warning  | Receive Warning   |
| Wake-up          | Wake-up   |

### 3.9.4.6 FlexCAN Operation in Low Power Modes

The FlexCAN module is operational in VLPR and VLPW modes. With the 2 MHz bus clock, the fastest supported FlexCAN transfer rate is 250 kbps. The bit timing parameters in the module must be adjusted for the new frequency, but full functionality is possible.

The FlexCAN module can be configured to generate a wakeup interrupt in STOP and VLPS modes. When the FlexCAN is configured to generate a wakeup, a recessive to dominant transition on the CAN bus generates an interrupt.

### 3.9.4.7 FlexCAN Doze Mode

The Doze mode for the FlexCAN module is the same as the Wait and VLPW modes for the chip.

## 3.9.5 SPI configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

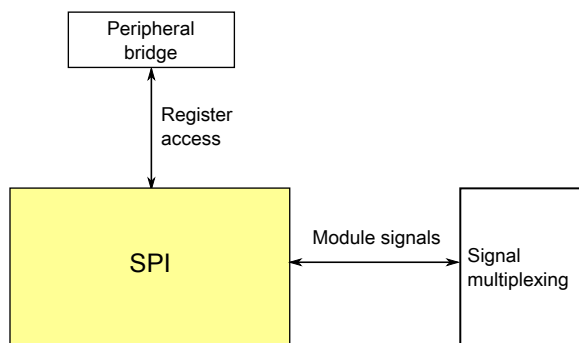

Figure 3-67. SPI configuration

Table 3-74. Reference links to related information

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | SPI            | <a href="#">SPI</a>                 |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock Distribution</a>  |
| Signal Multiplexing | Port control   | <a href="#">Signal Multiplexing</a> |

### 3.9.5.1 SPI Modules Configuration

This device contains three SPI modules.

### 3.9.5.2 SPI clocking

The SPI module is clocked by the internal bus clock (the DSPI refers to it as system clock). The module has an internal divider, with a minimum divide is two. So, the SPI can run at a maximum frequency of bus clock/2.

### 3.9.5.3 Number of CTARs

SPI CTAR registers define different transfer attribute configurations. The SPI module supports up to eight CTAR registers. This device supports two CTARs on all instances of the SPI.

In master mode, the CTAR registers define combinations of transfer attributes, such as frame size, clock phase, clock polarity, data bit ordering, baud rate, and various delays. In slave mode only CTAR0 is used, and a subset of its bitfields sets the slave transfer attributes.

### 3.9.5.4 TX FIFO size

Table 3-75. SPI transmit FIFO size

| SPI Module | Transmit FIFO size |
|------------|--------------------|
| SPI0       | 4                  |
| SPI1       | 4                  |
| SPI2       | 4                  |

### 3.9.5.5 RX FIFO Size

SPI supports up to 16-bit frame size during reception.

Table 3-76. SPI receive FIFO size

| SPI Module | Receive FIFO size |
|------------|-------------------|
| SPI0       | 4                 |
| SPI1       | 4                 |
| SPI2       | 4                 |

### 3.9.5.6 Number of PCS signals

The following table shows the number of peripheral chip select signals available per SPI module.

**Table 3-77. SPI PCS signals**

| SPI Module | PCS Signals            |
|------------|------------------------|
| SPI0       | SPI_PCS[5:0]           |
| SPI1       | SPI_PCS[3:0]           |
| SPI2       | SPI_PCS[1:0]SPI_PCS[0] |

### 3.9.5.7 SPI Operation in Low Power Modes

In VLPR and VLPW modes the SPI is functional; however, the reduced system frequency also reduces the max frequency of operation for the SPI. In VLPR and VLPW modes the max SPI\_CLK frequency is 2MHz.

In stop and VLPS modes, the clocks to the SPI module are disabled. The module is not functional, but it is powered so that it retains state.

There is one way to wake from stop mode via the SPI, which is explained in the following section.

#### 3.9.5.7.1 Using GPIO Interrupt to Wake from stop mode

Here are the steps to use a GPIO to create a wakeup upon reception of SPI data in slave mode:

1. Point the GPIO interrupt vector to the desired interrupt handler.
2. Enable the GPIO input to generate an interrupt on either the rising or falling edge (depending on the polarity of the chip select signal).
3. Enter Stop or VLPS mode and Wait for the GPIO interrupt.

**NOTE**

It is likely that in using this approach the first word of data from the SPI host might not be received correctly. This is dependent on the transfer rate used for the SPI, the delay between chip select assertion and presentation of data, and the system interrupt latency.

### 3.9.5.8 SPI Doze Mode

The Doze mode for the SPI module is the same as the Wait and VLPW modes for the chip.

### 3.9.5.9 SPI Interrupts

The SPI has multiple sources of interrupt requests. However, these sources are OR'd together to generate a single interrupt request per SPI module to the interrupt controller. When an SPI interrupt occurs, read the SPI\_SR to determine the exact interrupt source.

### 3.9.5.10 Writing SPI Transmit FIFO

In Master mode, only 32-bit write accesses are supported for the PUSHHR register, the top TX FIFO entry. In Slave mode, 8-bit, 16-bit and 32-bit write accesses are supported for the PUSHHR register, although each write increments the write pointer.

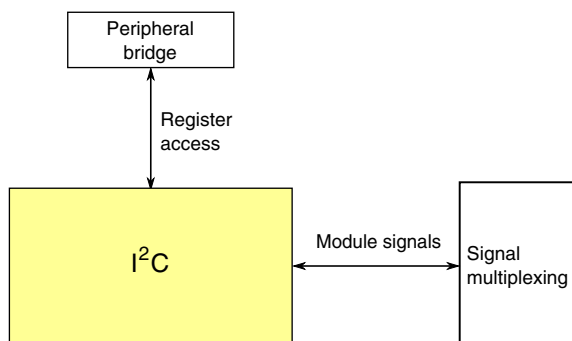

## 3.9.6 I2C Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

### NOTE

The Open Drain mode on SDA, SCL pins has to be enabled by setting PORTx\_PCRn[ODE] bits.

**Figure 3-68. I2C configuration**

**Table 3-78. Reference links to related information**

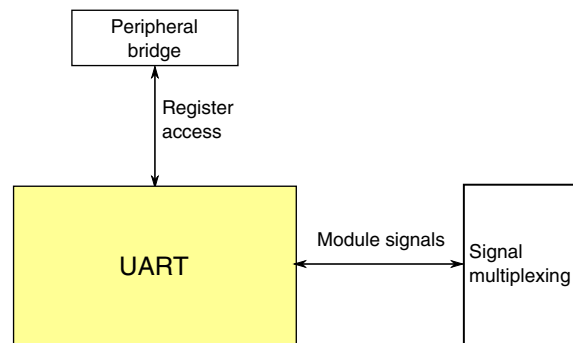

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | I2C            | <a href="#">I2C</a>                 |

| Clocking            |                | <a href="#">Clock Distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal Multiplexing | Port control   | <a href="#">Signal Multiplexing</a> |

### 3.9.6.1 Number of I2C modules

This device has two I<sup>2</sup>C modules.

## 3.9.7 UART Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

**Figure 3-69. UART configuration**
**Table 3-79. Reference links to related information**

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | UART           | <a href="#">UART</a>                |
| System memory map   |                | <a href="#">System memory map</a>   |
| Clocking            |                | <a href="#">Clock Distribution</a>  |
| Power management    |                | <a href="#">Power management</a>    |
| Signal Multiplexing | Port control   | <a href="#">Signal Multiplexing</a> |

### 3.9.7.1 UART configuration information

This chip contains six UART modules. This section describes how each module is configured on this device.

1. Standard features of all UARTs:
  - RS-485 support
  - Hardware flow control (RTS/CTS)
  - 9-bit UART to support address mark with parity
  - MSB/LSB configuration on data
2. UART0 and UART1 are clocked from the core clock, the remaining UARTs are clocked on the bus clock. The maximum baud rate is 1/16 of related source clock frequency.
3. IrDA is available on all UARTs
4. UART0 contains the standard features plus ISO7816
5. UART1 contains the standard features plus ISO7816
6. AMR support on all UARTs. The pin control and interrupts (PORT) module supports open-drain for all I/O.
7. UART0 and UART1 contain 8-entry transmit and 8-entry receive FIFOs
8. All other UARTs contain a 1-entry transmit and receive FIFOs
9. CEA709.1-B (LON) is available in UART0

### 3.9.7.2 UART wakeup

The UART can be configured to generate an interrupt/wakeup on the first active edge that it receives.

### 3.9.7.3 UART interrupts

The UART has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

The status interrupt combines the following interrupt sources:

| Source                   | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|--------------------------|--------|--------|--------|--------|--------|--------|
| Transmit data empty      | x      | x      | x      | x      | x      | x      |
| Transmit complete        | x      | x      | x      | x      | x      | x      |
| Idle line                | x      | x      | x      | x      | x      | x      |
| Receive data full        | x      | x      | x      | x      | x      | x      |
| LIN break detect         | x      | x      | x      | x      | x      | x      |
| RxD pin active edge      | x      | x      | x      | x      | x      | x      |
| Initial character detect | x      | x      | —      | —      | —      | —      |

The error interrupt combines the following interrupt sources:

| Source                      | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|-----------------------------|--------|--------|--------|--------|--------|--------|
| Receiver overrun            | x      | x      | x      | x      | x      | x      |
| Noise flag                  | x      | x      | x      | x      | x      | x      |
| Framing error               | x      | x      | x      | x      | x      | x      |
| Parity error                | x      | x      | x      | x      | x      | x      |
| Transmitter buffer overflow | x      | x      | x      | x      | x      | x      |
| Receiver buffer overflow    | x      | x      | x      | x      | x      | x      |
| Receiver buffer underflow   | x      | x      | x      | x      | x      | x      |

*Table continues on the next page...*

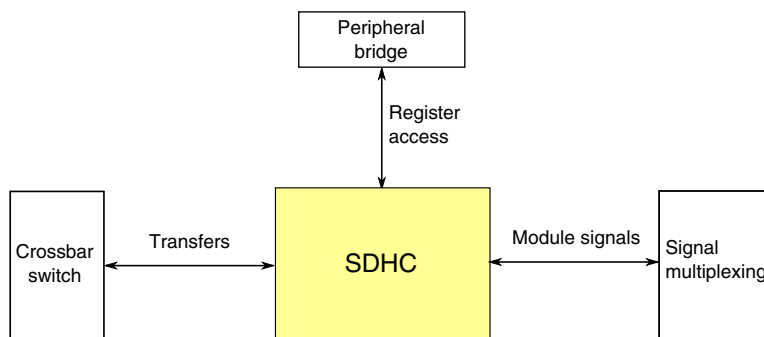

| Source                         | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|--------------------------------|--------|--------|--------|--------|--------|--------|
| Transmit threshold (ISO7816)   | x      | x      | —      | —      | —      | —      |
| Receiver threshold (ISO7816)   | x      | x      | —      | —      | —      | —      |
| Wait timer (ISO7816)           | x      | x      | —      | —      | —      | —      |
| Character wait timer (ISO7816) | x      | x      | —      | —      | —      | —      |
| Block wait timer (ISO7816)     | x      | x      | —      | —      | —      | —      |
| Guard time violation (ISO7816) | x      | x      | —      | —      | —      | —      |

The LON status interrupt combines the following interrupt sources:

| Source                                    | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|---|--------|--------|--------|--------|--------|--------|
| Wbase expire after beta1 time slots (LON) | x      | x      | —      | —      | —      | —      |
| Package received (LON)                    | x      | x      | —      | —      | —      | —      |
| Package transmitted (LON)                 | x      | x      | —      | —      | —      | —      |
| Package cycle time expired (LON)          | x      | x      | —      | —      | —      | —      |
| Preamble start (LON)                      | x      | x      | —      | —      | —      | —      |
| Transmission fail (LON)                   | x      | x      | —      | —      | —      | —      |
| Initial sync detection (LON)              | x      | x      | —      | —      | —      | —      |

### 3.9.8 SDHC Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 3-70. SDHC configuration**

**Table 3-80. Reference links to related information**

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|

### 3.9.8.1 SDHC clocking

In addition to the system clock, the SDHC needs a clock for the base for the external card clock. There are four possible clock sources for this clock, selected by the SIM\_SOPT2 register:

- Core/system clock
- MCGPLL0CLK, MCGPLL1CLK or MCGFLLCLK
- OSCERCLK
- Bypass clock from off-chip (SDHC0\_CLKIN)

### 3.9.8.2 SD bus pullup/pulldown constraints

The SD standard requires the SD bus signals (except the SD clock) to be pulled up during data transfers. The SDHC also provides a feature of detecting card insertion/removal, by detecting voltage level changes on DAT[3] of the SD bus. To support this DAT[3] must be pulled down. To avoid a situation where the SDHC detects voltage changes due to normal data transfers on the SD bus as card insertion/removal, the interrupt relating to this event must be disabled after the card has been inserted and detected. It can be re-enabled after the card is removed.

### 3.9.9 I<sup>2</sup>S configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

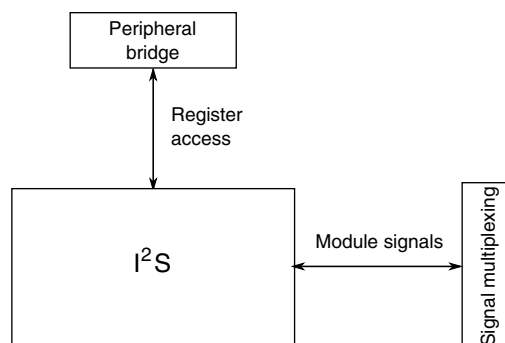

Figure 3-71. I<sup>2</sup>S configuration

Table 3-81. Reference links to related information

| Topic               | Related module   | Reference                           |
|---------------------|------------------|-------------------------------------|

| Signal multiplexing | Port control     | <a href="#">Signal Multiplexing</a> |

#### 3.9.9.1 Instantiation information

This device contains two I<sup>2</sup>S modules.

As configured on the device, module features include:

- TX data lines per module: 2
- RX data lines per module: 2
- FIFO size (words): 8
- Maximum words per frame: 32
- Maximum bit clock divider: 512

#### 3.9.9.2 I<sup>2</sup>S/SAI clocking

### 3.9.9.2.1 Audio Master Clock

The audio master clock (MCLK) is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The audio master clock can also be output to or input from a pin. The transmitter and receiver have the same audio master clock inputs.

### 3.9.9.2.2 Bit Clock

The I<sup>2</sup>S/SAI transmitter and receiver support asynchronous bit clocks (BCLKs) that can be generated internally from the audio master clock or supplied externally. The module also supports the option for synchronous operation between the receiver and transmitter product or between two separate I<sup>2</sup>S/SAI peripherals.

### 3.9.9.2.3 Bus Clock

The bus clock is used by the control registers and to generate synchronous interrupts and DMA requests.

### 3.9.9.2.4 I<sup>2</sup>S/SAI clock generation

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock.

The MCLK Input Clock Select bit of the MCLK Control Register (MCR[MICS]) selects the clock input to the I<sup>2</sup>S/SAI module's MCLK divider.

On this device, I2S0 and I2S1 have identical input clock selection options.

**Table 3-82. I2S0 and I2S1 MCLK input clock selection**

| MCR[MICS] | Clock Selection |
|-----------|-----------------|
| 00        | System clock    |
| 01        | OSC0ERCLK       |
| 10        | OSC1ERCLK       |
| 11        | MCGPLL0CLK      |

The module's MCLK Divide Register (MDR) configures the MCLK divide ratio.

The module's MCLK Output Enable bit of the MCLK Control Register (MCR[MOE]) controls the direction of the MCLK pin. The pin is the input from the pin when MOE is 0, and the pin is the output from the clock divider when MOE is 1.

The transmitter and receiver can independently select between the bus clock and the audio master clocks to generate the bit clock. Each module's Clocking Mode field of the Transmit Configuration 2 Register and Receive Configuration 2 Register (TCR2[MSEL] and RCR2[MSEL]) selects the master clock.

The following tables show the TCR2[MSEL] and RCR2[MSEL] field settings for the module instances on this device.

**Table 3-83. I2S0 master clock settings**

| TCR2[MSEL], RCR2[MSEL] | Master Clock   |
|------------------------|--|
| 00                     | Bus Clock  |
| 01                     | When MOE is 1: MCLK is generated internally from PLL, OSC, or system clock<br>When MOE is 0: I2S0_MCLK |
| 10                     | I2S1_MCLK  |
| 11                     | I2S1_MCLK  |

**Table 3-84. I2S1 master clock settings**

| TCR2[MSEL], RCR2[MSEL] | Master Clock   |
|------------------------|--|
| 00                     | Bus Clock  |
| 01                     | When MOE is 1: MCLK is generated internally from PLL, OSC, or system clock<br>When MOE is 0: I2S1_MCLK |
| 10                     | I2S0_MCLK  |
| 11                     | I2S0_MCLK  |

### 3.9.9.2.5 Clock gating and I<sup>2</sup>S/SAI initialization

The clock to the I<sup>2</sup>S/SAI module can be gated using a bit in the SIM. To minimize power consumption, these bits are cleared after any reset, which disables the clock to the corresponding module. The clock enable bit should be set by software at the beginning of the module initialization routine to enable the module clock before initialization of any of the I<sup>2</sup>S/SAI registers.

### 3.9.9.3 Multiple SAI Synchronous Mode

Multiple SAI Synchronous Mode is supported in both I2S0 and I2S1.

- For I2S1 to use I2S0's bit clock and frame sync, configure I2S1 as synchronous to another SAI peripheral, and configure I2S0 as asynchronous.
- For I2S0 to use I2S1's bit clock and frame sync, configure I2S0 as synchronous to another SAI peripheral, and configure I2S1 as asynchronous.

Note that transmit and receive are configured independently.

### 3.9.9.4 I<sup>2</sup>S/SAI operation in low power modes

#### 3.9.9.4.1 Stop and very low power modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In VLPS mode, the module behaves as it does in stop mode if VLPS mode is entered from run mode. However, if VLPS mode is entered from VLPR mode, the FIFO might underflow or overflow before wakeup from stop mode due to the limits in bus bandwidth. In VLPW and VLPR modes, the module is limited by the maximum bus clock frequencies.

When operating from an internally generated bit clock or Audio Master Clock that is disabled in stop modes:

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

#### 3.9.9.4.2 Low-leakage modes

When entering low-leakage modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

## 3.10 Human-machine interfaces

### 3.10.1 GPIO configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

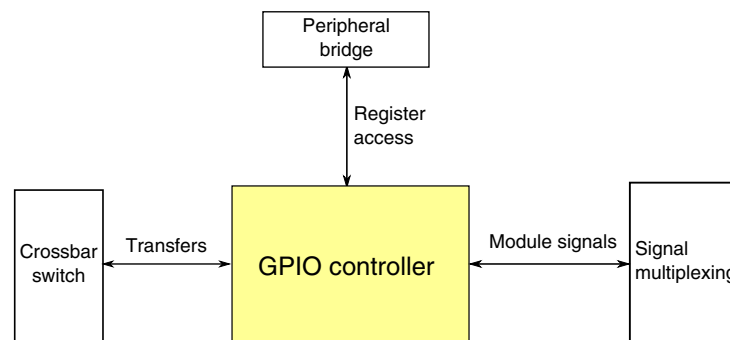

Figure 3-72. GPIO configuration

Table 3-85. Reference links to related information

| Topic               | Related module  | Reference                           |
|---------------------|-----------------|-------------------------------------|
| Full description    | GPIO            | <a href="#">GPIO</a>                |
| System memory map   |                 | <a href="#">System memory map</a>   |
| Clocking            |                 | <a href="#">Clock Distribution</a>  |
| Power management    |                 | <a href="#">Power management</a>    |
| Transfers           | Crossbar switch | <a href="#">Clock Distribution</a>  |
| Signal Multiplexing | Port control    | <a href="#">Signal Multiplexing</a> |

#### 3.10.1.1 GPIO access protection

The GPIO module does not have access protection because it is not connected to a peripheral bridge slot and is not protected by the MPU.

#### 3.10.1.2 Number of GPIO signals

The number of GPIO signals available on the devices covered by this document are detailed in [Orderable part numbers](#).

### 3.10.2 TSI Configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

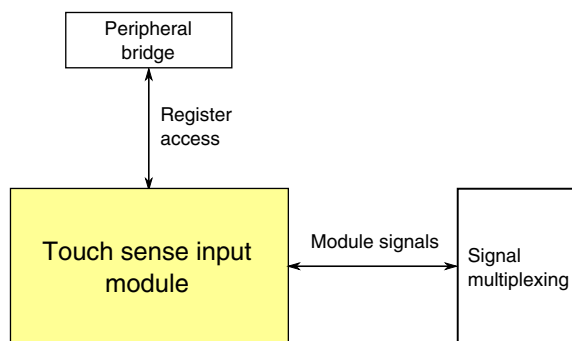

Figure 3-73. TSI configuration

Table 3-86. Reference links to related information

| Topic               | Related module | Reference                           |
|---------------------|----------------|-------------------------------------|
| Full description    | TSI            | <a href="#">TSI</a>                 |
| System memory map   |                | <a href="#">System memory map</a>   |

| Power management    |                | <a href="#">Power management</a>    |
| Signal Multiplexing | Port control   | <a href="#">Signal Multiplexing</a> |

#### 3.10.2.1 Number of inputs

This device includes one TSI module containing 16 inputs. In low-power modes, one selectable pin is active.

#### 3.10.2.2 TSI module functionality in MCU operation modes

Table 3-87. TSI module functionality in MCU operation modes

| MCU operation mode | TSI clock sources           | TSI operation mode when GENCS[TSIEN] is 1 | Functional electrode pins | Required GENCS[STPE] state |
|--------------------|-----------------------------|---|---------------------------|----------------------------|
| Run                | BUSCLK, MCGIRCLK, OSC0ERCLK | Active mode                               | All                       | Don't care                 |
| Wait               | BUSCLK, MCGIRCLK, OSC0ERCLK | Active mode                               | All                       | Don't care                 |

Table continues on the next page...

**Table 3-87. TSI module functionality in MCU operation modes (continued)**

| MCU operation mode | TSI clock sources           | TSI operation mode when GENCS[TSIEN] is 1 | Functional electrode pins | Required GENCS[STPE] state |
|--------------------|-----------------------------|---|---------------------------|----------------------------|
| Stop               | MCGIRCLK, OSC0ERCLK         | Active mode                               | All                       | 1                          |
| VLPR               | BUSCLK, MCGIRCLK, OSC0ERCLK | Active mode                               | All                       | Don't care                 |
| VLPW               | BUSCLK, MCGIRCLK, OSC0ERCLK | Active mode                               | All                       | Don't care                 |
| VLPS               | OSC0ERCLK                   | Active mode                               | All                       | 1                          |
| LLS                | LPOCLK, VLPOSCCLK           | Low power mode                            | Determined by PEN[LPSP]   | 1                          |
| VLLS3              | LPOCLK, VLPOSCCLK           | Low power mode                            | Determined by PEN[LPSP]   | 1                          |
| VLLS2              | LPOCLK, VLPOSCCLK           | Low power mode                            | Determined by PEN[LPSP]   | 1                          |
| VLLS1              | LPOCLK, VLPOSCCLK           | Low power mode                            | Determined by PEN[LPSP]   | 1                          |

### 3.10.2.3 TSI clocks

This table shows the TSI clocks and the corresponding chip clocks.

**Table 3-88. TSI clock connections**

| Module clock | Chip clock      |
|--------------|-----------------|
| BUSCLK       | Bus clock       |
| MCGIRCLK     | MCGIRCLK        |
| OSCERCLK     | OSC0ERCLK       |
| LPOCLK       | 1 kHz LPO clock |
| VLPOSCCLK    | ERCLK32K        |

### 3.10.2.4 TSI Interrupts

The TSI has multiple sources of interrupt requests. However, these sources are OR'd together to generate a single interrupt request. When a TSI interrupt occurs, read the TSI status register to determine the exact interrupt source.

### 3.10.2.5 Shield drive signal

The shield drive signal is not supported on this device. Ignore this feature in the TSI chapter.

# Chapter 4

## Memory Map

### 4.1 Introduction

This device contains various memories and memory-mapped peripherals which are located in one 32-bit contiguous memory space. This chapter describes the memory and peripheral locations within that memory space.

### 4.2 System memory map

The following table shows the high-level device memory map. This map provides the complete architectural address space definition for the various sections. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller.

**Table 4-1. System memory map**

| System 32-bit Address Range | Destination Slave  | Access                   | Slave Port |
|-----------------------------|--|--------------------------|------------|
| 0x0000_0000–0x07FF_FFFF     | Program flash and read-only data<br>(Includes exception vectors in first 1024 bytes)                               | All masters              | S0         |
| 0x0800_0000–0x0FFF_FFFF     | DRAM Controller (Aliased Area)   | Cortex-M4 core (M0) only | S5         |
| 0x1000_0000–0x13FF_FFFF     | FlexNVM  | All masters              | S0         |
| 0x1000_0000–0x13FF_FFFF     | Reserved   | –                        | –          |
| 0x1400_0000–0x17FF_FFFF     | For devices with FlexNVM: FlexRAM  | All masters              | S0         |
| 0x1400_0000–0x17FF_FFFF     | For devices with program flash only: Programming acceleration RAM  | –                        | S0         |
| 0x1800_0000–0x1BFF_FFFF     | FlexBus (Aliased Area).<br>0x1800_0000-0x1BFF_FFFF are mapped to the same access space of 0x9800_0000-0x9BFF_FFFF. | Cortex-M4 core (M0) only | –          |
| 0x1C00_0000–0x1FFF_FFFF     | SRAM_L: Lower SRAM (ICODE/DCODE)   | All masters              | –          |
| 0x2000_0000–0x200F_FFFF     | SRAM_U: Upper SRAM bitband region  | All masters              | –          |
| 0x2010_0000–0x21FF_FFFF     | Reserved   | –                        | –          |

*Table continues on the next page...*

**Table 4-1. System memory map (continued)**

| System 32-bit Address Range | Destination Slave                              | Access                      | Slave Port |
|-----------------------------|--|-----------------------------|------------|
| 0x2200_0000–0x23FF_FFFF     | Aliased to TCMU SRAM bitband                   | Cortex-M4 core only         | –          |
| 0x2400_0000–0x3FFF_FFFF     | Reserved                                       | –                           | –          |
| 0x4000_0000–0x4007_FFFF     | Bitband region for AIPS0                       | Cortex-M4 core & DMA/EzPort | S2         |
| 0x4008_0000–0x400F_EFFF     | Bitband region for AIPS1                       | Cortex-M4 core & DMA/EzPort | S3         |
| 0x400F_F000–0x400F_FFFF     | Bitband region for GPIO                        | Cortex-M4 core & DMA/EzPort | S3         |
| 0x4010_0000–0x41FF_FFFF     | Reserved                                       | –                           | –          |
| 0x4200_0000–0x43FF_FFFF     | Aliased to AIPS and GPIO bitband               | Cortex-M4 core only         | –          |
| 0x4400_0000–0x5FFF_FFFF     | Reserved                                       | –                           | –          |
| 0x6000_0000–0x6FFF_FFFF     | Flexbus (External memory - Write-back)         | All masters                 | S4         |
| 0x9000_0000–0x9FFF_FFFF     | FlexBus (External memory - Write-through)      | All masters                 | S4         |
| 0xA000_0000–0xDFFF_FFFF     | FlexBus (External peripheral - not executable) | All masters                 | S4         |
| 0xE000_0000–0xE00F_FFFF     | Private Peripherals                            | Cortex-M4 core only         | –          |
| 0xE010_0000–0xFFFF_FFFF     | Reserved                                       | –                           | –          |

**NOTE**

1. EzPort master port is statically muxed with DMA master port. Access rights to AIPS-Lite peripheral bridges and general purpose input/output (GPIO) module address space is limited to the core, DMA and EzPort.
2. ARM Cortex-M4 core access privileges also includes accesses via the debug interface.

**4.2.1 Aliased bit-band regions**

The SRAM\_U, AIPS-Lite, and general purpose input/output (GPIO) module resources reside in the Cortex-M4 processor bit-band regions.

The processor also includes two 32 MB aliased bit-band regions associated with the two 1 MB bit-band spaces. Each 32-bit location in the 32 MB space maps to an individual bit in the bit-band region. A 32-bit write in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

Bit 0 of the value written to the alias region determines what value is written to the target bit:

- Writing a value with bit 0 set writes a 1 to the target bit.
- Writing a value with bit 0 clear writes a 0 to the target bit.

A 32-bit read in the alias region returns either:

- a value of 0x0000\_0000 to indicate the target bit is clear
- a value of 0x0000\_0001 to indicate the target bit is set

**Figure 4-1. Alias bit-band mapping**

**NOTE**

Each bit in bit-band region has an equivalent bit that can be manipulated through bit 0 in a corresponding long word in the alias bit-band region.

### 4.2.2 Aliased areas

The Flexbus and DDR controller have has several aliased regions to allow the user to access the same physical area of memory with different cache attributes.

### 4.2.2.1 DDR controller aliased areas

For the DDR controller, there are aliased regions to allow the user to differentiate between write-through and write-back cache accesses. There is also a smaller aliased area that allows accesses through the system bus. The following figures show the organization of the aliased areas, depending on MCM\_CR[DDRSIZE] bitfield setting.

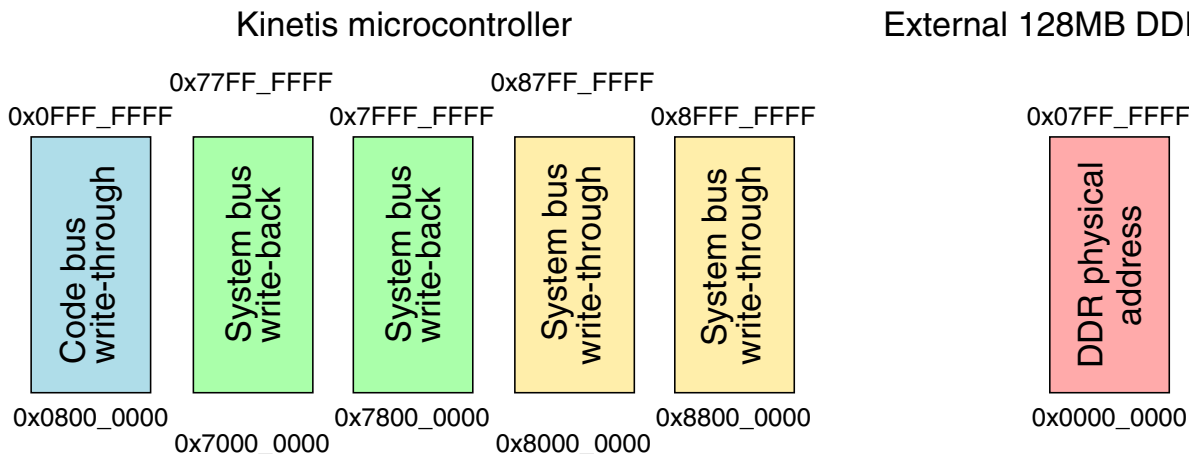

Figure 4-2. DDR aliased regions (MCM\_CR[DDRSIZE] = 01)

**NOTE**

In the preceding figure, all the regions are mapped to the same physical address.

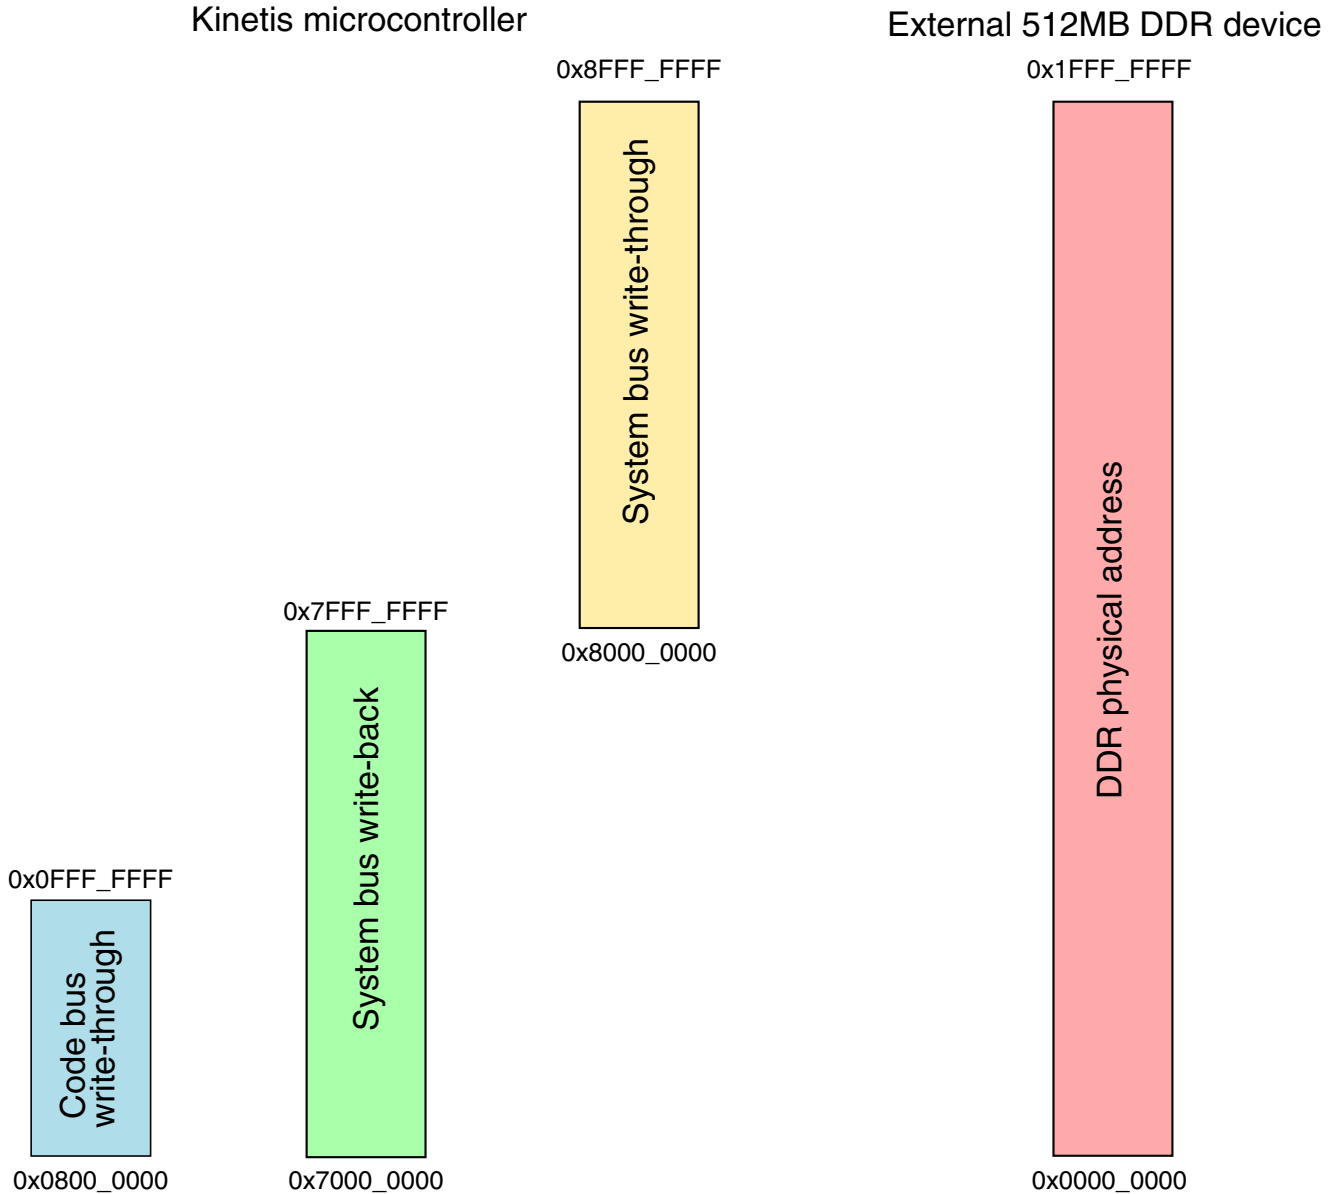

Figure 4-3. DDR aliased regions (MCM\_CR[DDRSIZE] = 10)

**NOTE**

In the preceding figure, both system bus write-through and write-back regions are 256 MB and are mapped to physical address. Code bus alias region is 128 MB and is mapped to lower 128 MB of DRAM physical address:  
0x0000\_0000-0x07FF\_FFFF.

**Figure 4-4. DDR aliased regions (MCM\_CR[DDRSIZE] = 11)**

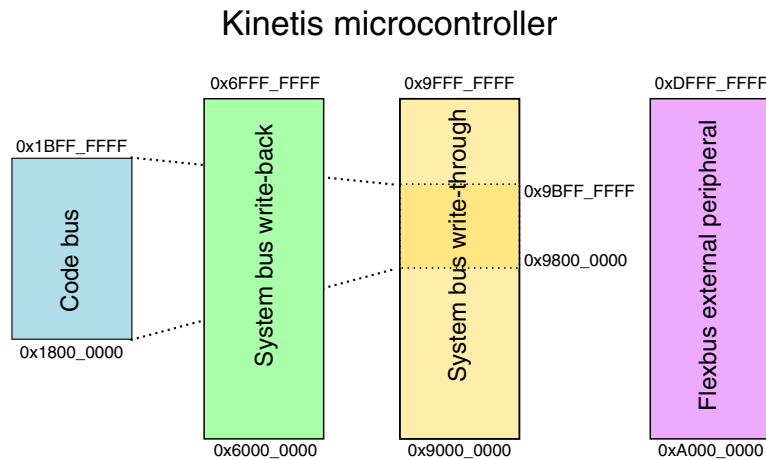

**NOTE**

In the preceding figure, system bus write-back region is 256 MB and mapped to lower part of DRAM physical address space. System bus write-through region is 256 MB and mapped

to higher part of DRAM physical address space. Code bus alias region is 128 MB and is mapped to lower part of physical address space.

### 4.2.2.2 FlexBus aliased areas

For the FlexBus write-through, write-back and non-executable regions are available. The mapping from the internal memory map area to the external memory device is determined by the Flexbus register settings and the physical address signal connections.

**Note:** The aliased region accessible by the system bus is directly remapped from the I/D bus write-through region.

**Figure 4-5. Flexbus aliased regions**

#### NOTE

- In the preceding figure, code bus alias region is mapped to system bus region:0x9800\_0000-0x9BFF\_FFFF.
- Set the FB\_CSARx to 0x1800\_0000 to use the address space from 0x9800\_0000.

## 4.3 Flash Memory Map

The various flash memories and the flash registers are located at different base addresses as shown in the following figure. The base address for each is specified in [System memory map](#).

**Figure 4-6. Flash memory map for devices containing only program flash**

**Figure 4-7. Flash memory map for devices containing FlexNVM**

### 4.3.1 Alternate Non-Volatile IRC User Trim Description

The following non-volatile locations (4 bytes) are reserved for custom IRC user trim supported by some development tools. An alternate IRC trim to the factory loaded trim can be stored at this location. To override the factory trim, user software must load new values into the MCG trim registers.

| Non-Volatile Byte Address | Alternate IRC Trim Value |
|---------------------------|--------------------------|
| 0x0000_03FC               | Reserved                 |
| 0x0000_03FD               | Reserved                 |
| 0x0000_03FE (bit 0)       | SCFTRIM                  |
| 0x0000_03FE (bit 4:1)     | FCTRIM                   |
| 0x0000_03FF               | SCTRIM                   |

## 4.4 SRAM memory map

The on-chip RAM is split in two regions: SRAM\_L and SRAM\_U. The RAM is implemented such that the SRAM\_L and SRAM\_U ranges form a contiguous block in the memory map. See [SRAM Configuration](#) for details.

Accesses to the SRAM\_L and SRAM\_U memory ranges outside the amount of RAM on the device causes the bus cycle to be terminated with an error followed by the appropriate response in the requesting bus master.

## 4.5 Peripheral bridge (AIPS-Lite0 and AIPS-Lite1) memory maps

The peripheral memory map is accessible via two slave ports on the crossbar switch in the 0x4000\_0000–0x400F\_FFFF region. The device implements two peripheral bridges (AIPS-Lite 0 and 1):

- AIPS-Lite0 covers 512 KB
- AIPS-Lite1 covers 508 KB with 4 KB assigned to the general purpose input/output module (GPIO)

AIPS-Lite0 is connected to crossbar switch slave port 2, and is accessible at locations 0x4000\_0000–0x4007\_FFFF.

AIPS-Lite1 and the general purpose input/output module share the connection to crossbar switch slave port 3. The AIPS-Lite1 is accessible at locations 0x4008\_0000–0x400F\_EFFF. The general purpose input/output module is accessible in a 4-kbyte region at 0x400F\_F000–0x400F\_FFFF. Its direct connection to the crossbar switch provides master access without incurring wait states associated with accesses via the AIPS-Lite controllers.

Modules that are disabled via their clock gate control bits in the SIM registers disable the associated AIPS slots. Access to any address within an unimplemented or disabled peripheral bridge slot results in a transfer error termination.

For programming model accesses via the peripheral bridges, there is generally only a small range within the 4 KB slots that is implemented. Accessing an address that is not implemented in the peripheral results in a transfer error termination.

## 4.5.1 Read-after-write sequence and required serialization of memory operations

In some situations, a write to a peripheral must be completed fully before a subsequent action can occur. Examples of such situations include:

- Exiting an interrupt service routine (ISR)
- Changing a mode
- Configuring a function

In these situations, the application software must perform a read-after-write sequence to guarantee the required serialization of the memory operations:

1. Write the peripheral register.
2. Read the written peripheral register to verify the write.
3. Continue with subsequent operations.

## 4.5.2 Peripheral Bridge 0 (AIPS-Lite 0) Memory Map

Table 4-2. Peripheral bridge 0 slot assignments

| System 32-bit base address | Slot number | Module                                      |
|----------------------------|-------------|---|
| 0x4000_0000                | 0           | Peripheral bridge 0 (AIPS-Lite 0)—          |

## 4.6 Private Peripheral Bus (PPB) memory map

The PPB is part of the defined ARM bus architecture and provides access to select processor-local modules. These resources are only accessible from the core; other system masters do not have access to them.

**Table 4-4. PPB memory map**

| System 32-bit Address Range | Resource  |
|-----------------------------|---|
| 0xE000_0000–0xE000_0FFF     | Instrumentation Trace Macrocell (ITM)                         |
| 0xE000_1000–0xE000_1FFF     | Data Watchpoint and Trace (DWT)                               |

# Chapter 5

## Clock Distribution

### 5.1 Introduction

The MCG module controls which clock source is used to derive the system clocks. The clock generation logic divides the selected clock source into a variety of clock domains, including the clocks for the system bus masters, system bus slaves, and flash memory . The clock generation logic also implements module-specific clock gating to allow granular shutoff of modules.

The primary clocks for the system are generated from the MCGOUTCLK clock. The clock generation circuitry provides several clock dividers that allow different portions of the device to be clocked at different frequencies. This allows for trade-offs between performance and power dissipation.

Various modules, such as the USB OTG Controller, have module-specific clocks that can be generated from the MCGPLL0CLK, MCGPLL1CLK, or MCGFLLCLK clock. In addition, there are various other module-specific clocks that have other alternate sources. Clock selection for most modules is controlled by the SOPT registers in the SIM module.

### 5.2 Programming model

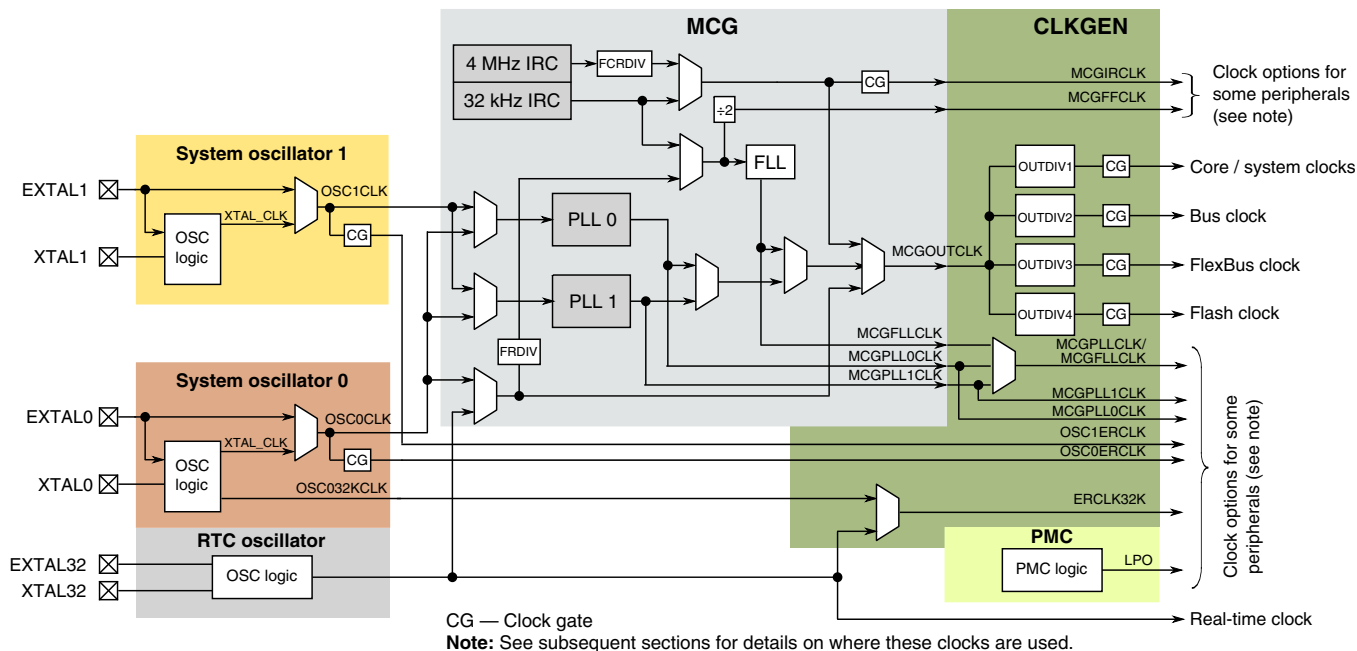

The selection and multiplexing of system clock sources is controlled and programmed via the MCG module. The setting of clock dividers and module clock gating for the system are programmed via the SIM module. Reference those sections for detailed register and bit descriptions.

### 5.3 High-level device clocking diagram

The following [system oscillator](#), [MCG](#), and [SIM](#) module registers control the multiplexers, dividers, and clock gates shown in the below figure:

## Clock definitions

|              | OSC    | MCG    | SIM                  |
|--------------|--------|--------|----------------------|
| Multiplexers | MCG_Cx | MCG_Cx | SIM_SOPT1, SIM_SOPT2 |
| Dividers     | —      | MCG_Cx | SIM_CLKDIVx          |
| Clock gates  | OSC_CR | MCG_C1 | SIM_SCGCx            |

**Figure 5-1. Clocking diagram**

## 5.4 Clock definitions

The following table describes the clocks in the previous block diagram.

| Clock name    | Description  |
|---------------|--|
| Core clock    | MCGOUTCLK divided by OUTDIV1 clocks the ARM Cortex-M4 core   |
| System clock  | MCGOUTCLK divided by OUTDIV1 clocks the crossbar switch and bus masters directly connected to the crossbar. In addition, this clock is used for UART0 and UART1. |
| Bus clock     | MCGOUTCLK divided by OUTDIV2 clocks the bus slaves and peripheral (excluding memories)   |
| FlexBus clock | MCGOUTCLK divided by OUTDIV3 clocks the external FlexBus interface   |
| Flash clock   | MCGOUTCLK divided by OUTDIV4 clocks the flash memory   |
| MCGIRCLK      | MCG output of the slow or fast internal reference clock  |
| MCGFFCLK      | MCG output of the slow internal reference clock or a divided MCG external reference clock.   |

Table continues on the next page...

| <b>Clock name</b>    | <b>Description</b>  |
|----------------------|---|
| MCGOUTCLK            | MCG output of either IRC, MCGFLLCLK MCGPLL0CLK, MCGPLL1CLK, or MCG's external reference clock that sources the core, system, bus, FlexBus, and flash clock. It is also an option for the debug trace clock. |
| MCGFLLCLK            | MCG output of the FLL. MCGFLLCLK may clock some modules.  |
| MCGPLL0CLK           | MCG output of the PLL0. MCGPLL0CLK may clock some modules.  |
| MCGPLL1CLK           | MCG output of the PLL1. MCGPLL1CLK may clock some modules.  |
| MCGPLLCLK/MCGFLLCLK  | Selectable clock source from the FLL, PLL0 or PLL1 controlled by the SIM.   |
| OSC0CLK, OSC1CLK     | System oscillator output of the internal oscillators or sourced directly from EXTAL   |
| OSC0ERCLK, OSC1ERCLK | System oscillator output sourced from OSC0CLK or OSC1CLK that may clock some on-chip modules  |
| OSC032KCLK           | System oscillator 0 32kHz output  |
| ERCLK32K             | Clock source for some modules that is chosen as OSC0_32KCLK or the RTC clock. It is VLPOSCCLK for TSI.  |
| RTC clock            | RTC oscillator output for the RTC module and the DryIce module  |
| LPO                  | PMC 1kHz output   |

## 5.4.1 Device clock summary

The following table provides more information regarding the on-chip clocks.

**Table 5-1. Clock Summary**

| <b>Clock name</b>         | <b>Run mode<br/>clock frequency</b> | <b>VLPR mode<br/>clock frequency</b>          | <b>Clock source</b>     | <b>Clock is disabled<br/>when...</b>  |
|---------------------------|-------------------------------------|---|-------------------------|---------------------------------------|
| MCGOUTCLK                 | Up to 150 MHz                       | Up to 8 MHz                                   | MCG                     | In all stop modes                     |
| Core clock                | Up to 150 MHz                       | Up to 4 MHz                                   | MCGOUTCLK clock divider | In all wait and stop modes            |
| System clock              | Up to 150 MHz                       | Up to 4 MHz                                   | MCGOUTCLK clock divider | In all stop modes                     |
| Bus clock                 | Up to 75 MHz                        | Up to 4 MHz                                   | MCGOUTCLK clock divider | In all stop modes                     |
| FlexBus clock<br>(FB_CLK) | Up to 50 MHz                        | Up to 4 MHz                                   | MCGOUTCLK clock divider | In all stop modes or FlexBus disabled |
| Flash clock               | Up to 25 MHz                        | Up to 1 MHz in BLPE,<br>Up to 800 kHz in BLPI | MCGOUTCLK clock divider | In all stop modes                     |

*Table continues on the next page...*

**Table 5-1. Clock Summary (continued)**

| Clock name                                | Run mode clock frequency                                      | VLPR mode clock frequency   | Clock source   | Clock is disabled when...  |
|---|---|---|--|--|
| Internal reference (MCGIRCLK)             | 30-40 kHz or 4 MHz  | 4 MHz only  | MCG  | MCG_C1[IRCLKEN] cleared,<br>Stop mode and MCG_C1[IREFSTEN] cleared, or<br>VLPS/LLS/VLLS mode |
| External reference (OSC0ERCLK, OSC1ERCLK) | Up to 50 MHz (bypass),<br>30-40 kHz, or<br>3-32 MHz (crystal) | Up to 8 MHz (bypass),<br>30-40 kHz (low-range crystal) or<br>Up to 4 MHz (high-range crystal) | System OSC   | System OSC's OSC_CR[ERCLKEN] cleared, or<br>Stop mode and OSC_CR[EREFSTEN] cleared           |
| External reference 32kHz (ERCLK32K)       | 30-40 kHz   | 30-40 kHz   | System OSC0 or RTC OSC depending on SIM_SOPT1[OSC32KSEL]   | System OSC's OSC_CR[ERCLKEN] cleared or<br>RTC's RTC_CR[OSCE] cleared                        |
| RTC_CLKOUT                                | 1 Hz or 32 kHz  | 1 Hz or 32 kHz  | RTC clock  | Clock is disabled in LLS and VLLSx modes   |
| LPO                                       | 1 kHz   | 1 kHz   | PMC  | Available in all power modes   |
| USB HS clock                              | 60 MHz  | N/A   | Bus clock, MCGPLL0CLK, MCGPLL1CLK, or OSC0ERCLK with fractional clock divider, or<br>ULPI_CLK      | USB HS OTG is disabled   |
| USB FS clock                              | 48 MHz  | N/A   | MCGPLL0CLK, MCGPLL1CLK, or MCGFLLCLK with fractional clock divider, or<br>USB_CLKIN                | USB FS OTG is disabled   |
| I2S master clock                          | Up to 25 MHz  | Up to 12.5 MHz  | System clock , MCGPLL0CLK , OSC0ERCLK, or OSC1ERCLK with fractional clock divider, or<br>I2S_CLKIN | I2S is disabled  |
| SDHC clock                                | Up to 50 MHz  | N/A   | System clock, MCGPLLCLK/ MCGFLLCLK, or<br>OSC0ERCLK  | SDHC is disabled   |
| Ethernet RMII clock                       | 50 MHz  | N/A   | OSC0ERCLK  | Ethernet is disabled   |

Table continues on the next page...

**Table 5-1. Clock Summary (continued)**

| Clock name               | Run mode clock frequency | VLPR mode clock frequency | Clock source  | Clock is disabled when... |
|--------------------------|--------------------------|---------------------------|---|---------------------------|
| Ethernet IEEE 1588 clock | Up to 100 MHz            | N/A                       | System clock, OSC0ERCLK, MCGPLLCLK/ MCGFLLCLK, or ENET_1588_CLKIN | Ethernet is disabled      |
| TRACE clock              | Up to 100 MHz            | Up to 4 MHz               | System clock or MCGOUTCLK   | Trace is disabled         |

## 5.5 Internal clocking requirements

Each system clock divider is programmed via the SIM module's CLKDIV registers. Each divider is programmable from a divide-by-1 through divide-by-16 setting. The following requirements must be met when configuring the system clocks for this device:

1. The core and system clock frequencies frequency must be 150 MHz or slower.
2. The bus clock frequency must be 75 MHz or slower and an integer divide of the core clock.
3. The flash clock frequency must be 25 MHz or slower and an integer divide of the bus clock.

The following are examples of valid clock configurations for this device:

Option 1:

| Clock       | Frequency |
|-------------|-----------|
| Core clock  | 150 MHz   |
| Bus clock   | 75 MHz    |
| Flash clock | 25 MHz    |

Option 2:

| Clock       | Frequency |
|-------------|-----------|
| Core clock  | 120 MHz   |
| Bus clock   | 60 MHz    |
| Flash clock | 20 MHz    |

### 5.5.1 Clock divider values after reset

Each clock divider is programmed via the SIM module's CLKDIV $n$  registers. The flash memory's FTF\_FOPT[LPBOOT] bit controls the reset value of the core clock, system clock, bus clock, and flash clock dividers as shown below:

| FTF_FOPT [LPBOOT] | Core/system clock | Bus clock         | FlexBus clock      | Flash clock        | Description     |
|-------------------|-------------------|-------------------|--------------------|--------------------|-----------------|
| 0                 | 0x7 (divide by 8) | 0x7 (divide by 8) | 0xF (divide by 16) | 0xF (divide by 16) | Low power boot  |
| 1                 | 0x0 (divide by 1) | 0x0 (divide by 1) | 0x1 (divide by 2)  | 0x1 (divide by 2)  | Fast clock boot |

This gives the user flexibility for a lower frequency, low-power boot option. The flash erased state defaults to fast clocking mode, since where the low power boot (FTF\_FOPT[LPBOOT]) bit resides in flash is logic 1 in the flash erased state.

To enable the low power boot option program FTF\_FOPT[LPBOOT] to zero. During the reset sequence, if LPBOOT is cleared, the system is in a slow clock configuration. Upon any system reset, the clock dividers return to this configurable reset state.

### 5.5.2 VLPR mode clocking

The clock dividers cannot be changed while in VLPR mode. They must be programmed prior to entering VLPR mode to guarantee:

- the core/system, FlexBus, and bus clocks are less than or equal to 4 MHz, and
- the flash memory clock is less than or equal to 1 MHz

**NOTE**

When the MCG is in BLPI and clocking is derived from the Fast IRC, the clock divider controls, MCG\_SC[FCRDIV] and SIM\_CLKDIV1[OUTDIV4], must be programmed such that the resulting flash clock nominal frequency is 800 kHz or less. In this case, one example of correct configuration is MCG\_SC[FCRDIV]=000b and SIM\_CLKDIV1[OUTDIV4]=0100b, resulting in a divide by 5 setting.

## 5.6 Clock Gating

The clock to each module can be individually gated on and off using the SIM module's SCGCx registers. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing a module, set the corresponding bit in SCGCx register to enable the clock. Before turning off the clock, make sure to disable the module.

Any bus access to a peripheral that has its clock disabled generates an error termination.

## 5.7 Module clocks

The following table summarizes the clocks associated with each module.

**Table 5-2. Module clocks**

| Module                | Bus interface clock | Internal clocks | I/O interface clocks |
|-----------------------|---------------------|-----------------|----------------------|
| <b>Core modules</b>   |                     |                 |                      |
| ARM Cortex-M4 core    | System clock        | Core clock      | —                    |
| NVIC                  | System clock        | —               | —                    |

### 5.7.1 PMC 1-kHz LPO clock

The Power Management Controller (PMC) generates a 1-kHz clock that is enabled in all modes of operation, including all low power modes. This 1-kHz source is commonly referred to as LPO clock or 1-kHz LPO clock.

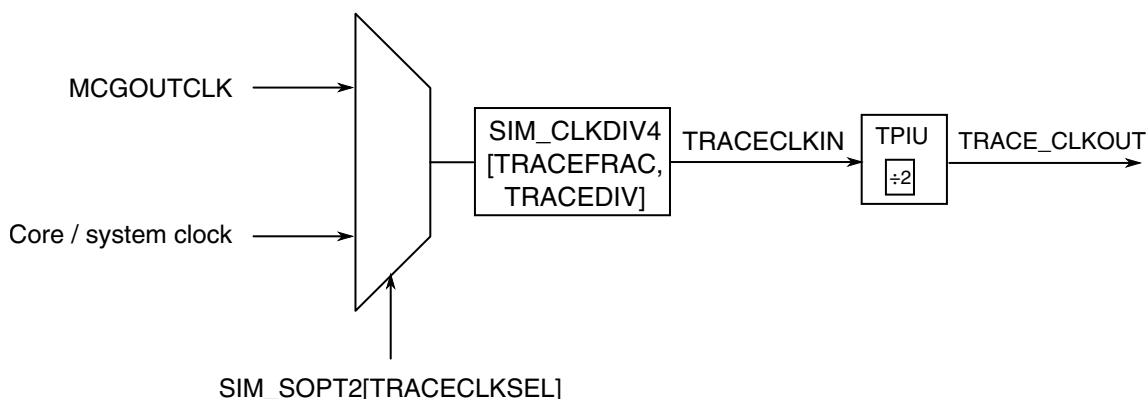

### 5.7.2 WDOG clocking

The WDOG may be clocked from two clock sources as shown in the following figure.

**Figure 5-2. WDOG clock generation**

### 5.7.3 Debug trace clock

The debug trace clock source can be clocked as shown in the following figure.

**Figure 5-3. Trace clock generation**

**NOTE**

The trace clock frequency observed at the TRACE\_CLKOUT pin will be half that of the selected clock source.

### 5.7.4 PORT digital filter clocking

The digital filters in each of the PORT<sub>x</sub> modules can be clocked as shown in the following figure.

**NOTE**

In stop mode, the digital input filters are bypassed unless they are configured to run from the 1 kHz LPO clock source.

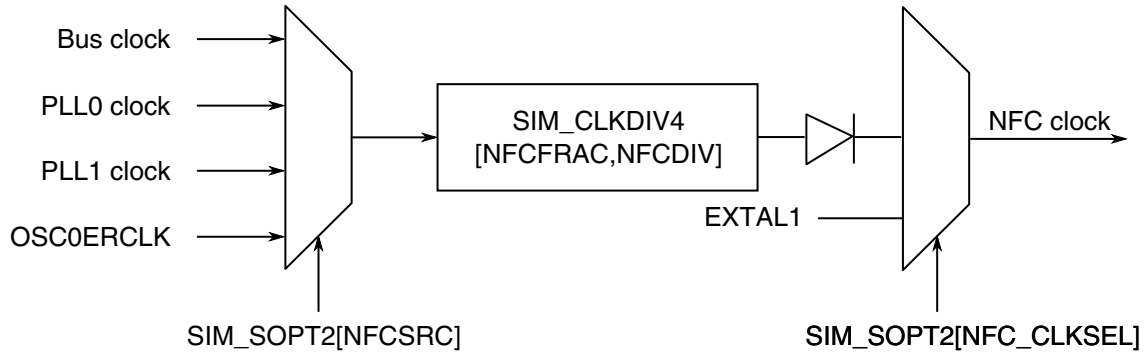

**Figure 5-4. PORT<sub>x</sub> digital input filter clock generation**

### 5.7.5 NAND Flash Controller (NFC) clocking

The NAND Flash Controller's clock source is determined by the SIM\_SOPT2[NFCSRC] bitfield and the SIM\_CLKDIV4[NFCFRAC, NFCDIV] bitfields as shown below.

### NOTE

The reciprocal of  $((\text{NFCFRAC}+1)/(\text{NFCDIV}+1))$  must be a multiple of 0.5. For example,  $\text{NFCFRAC} = 1$  and  $\text{NFCDIV} = 2$  is a valid setting, since the reciprocal is 1.5. However,  $\text{NFCFRAC} = 2$  and  $\text{NFCDIV}=7$  is not a valid setting, since the reciprocal is 2.6667.

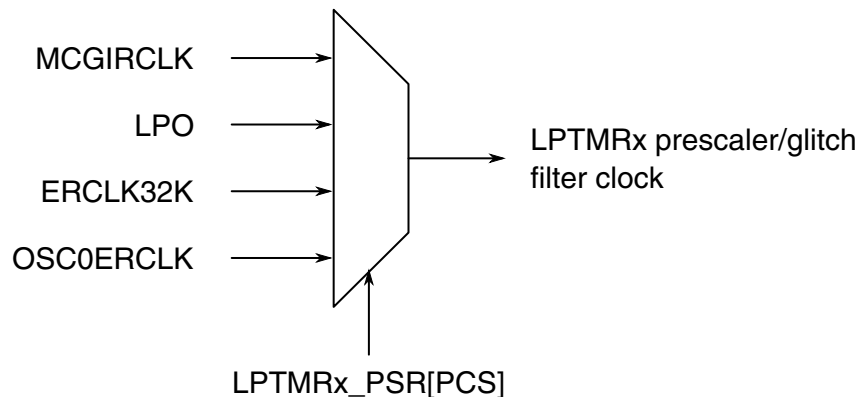

**Figure 5-5. NFC clock generation**

### 5.7.6 LPTMR clocking

The prescaler and glitch filters in each of the LPTMR<sub>x</sub> modules can be clocked as shown in the following figure.

### NOTE

The chosen clock must remain enabled if the LPTMR<sub>x</sub> is to continue operating in all required low-power modes.

**Figure 5-6. LPTMRx prescaler/glitch filter clock generation**

## 5.7.7 Ethernet Clocking

- The RMI clock source is fixed to OSC0ERCLK and must be 50 MHz
- The MII clocks are supplied from pins and must be 25 MHz
- The IEEE 1588 timestamp clock can run up to 100 MHz, if generated from internal clock sources. Its period must be an integer number of nanoseconds (eg: 10ns = 100 MHz, 15ns = 66.67 MHz, 20ns = 50 MHz). Its clock source is chosen as shown in the following figure.

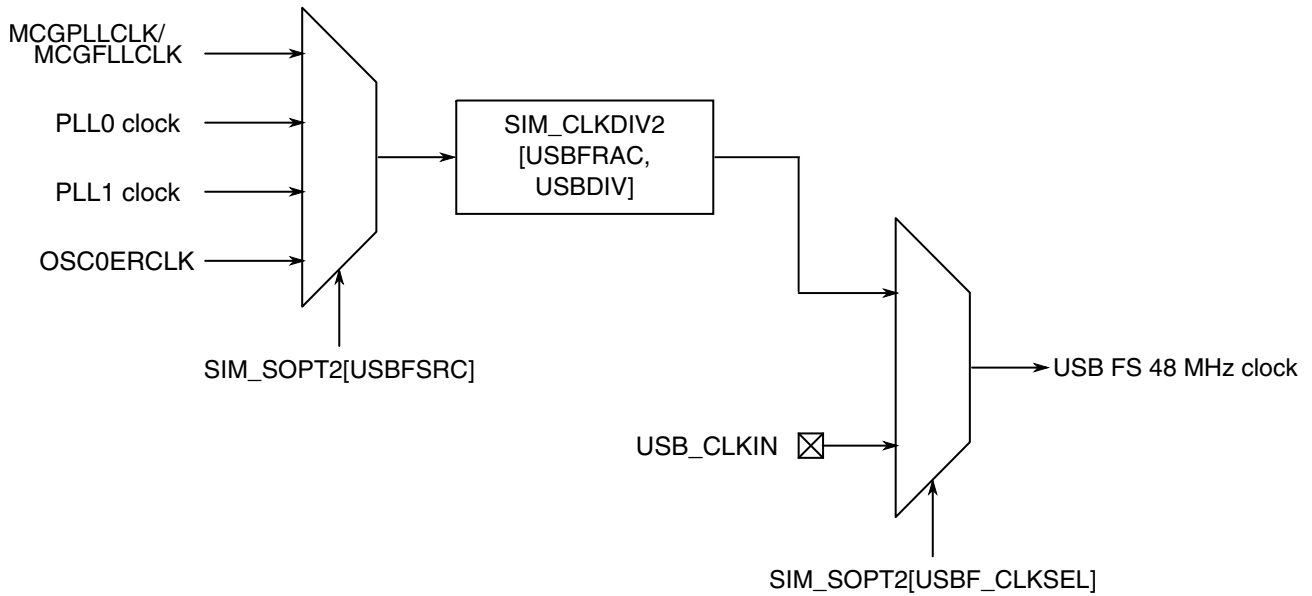

**Figure 5-7. Ethernet IEEE1588 timestamp clock generation**

## 5.7.8 USB FS OTG Controller clocking

The USB FS OTG controller clocking options are shown in the following figure.

### NOTE

For the USB FS OTG controller to operate, the minimum system clock frequency is 20 MHz.

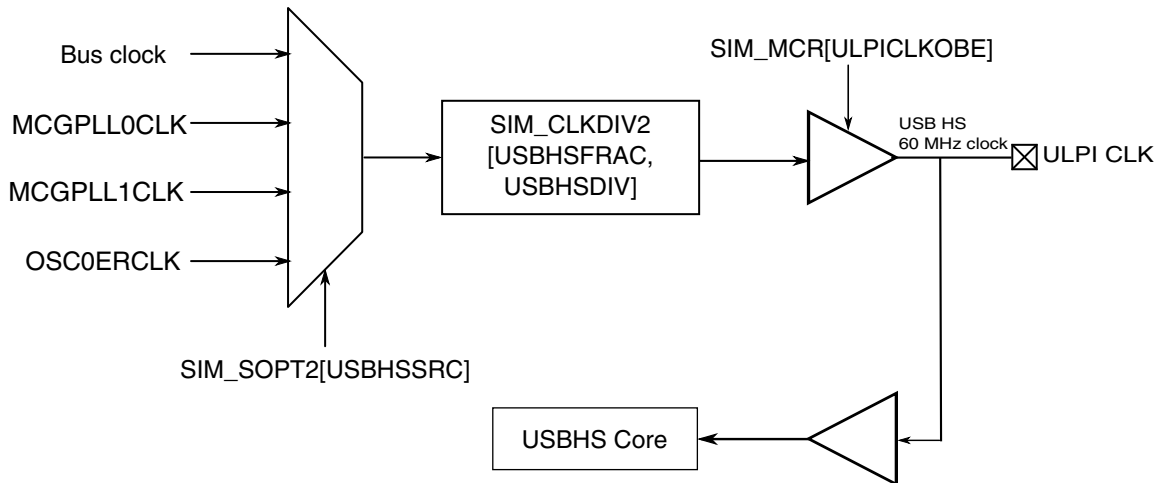

**Figure 5-8. USB FS clock generation**

**NOTE**

The MCGFLLCLK does not meet the USB jitter specifications for certification.

**5.7.9 USB HS OTG Controller clocking**

The USB HS OTG controller clocking options are shown in the following figure.

**Figure 5-9. USB HS clock generation**

### 5.7.10 FlexCAN clocking

The clock for the FlexCAN's protocol engine can be selected as shown in the following figure.

**Figure 5-10. FlexCAN clock generation**

### 5.7.11 UART clocking

UART0 and UART1 modules operate from the core/system clock, which provides higher performance level for these modules. All other UART modules operate from the bus clock.

### 5.7.12 SDHC clocking

The SDHC module has four possible clock sources for the external clock source, as shown in the following figure.

**Figure 5-11. SDHC clock generation**

### 5.7.13 I<sup>2</sup>S/SAI clocking

The audio master clock (MCLK) is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The audio master clock can also be output to or input from a pin. The transmitter and receiver have the same audio master clock inputs.

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock.

The I<sup>2</sup>S/SAI transmitter and receiver support asynchronous bit clocks (BCLKs) that can be generated internally from the audio master clock or supplied externally. The module also supports the option for synchronous operation between the receiver and transmitter product or between two separate I<sup>2</sup>S/SAI peripherals.

The transmitter and receiver can independently select between the bus clock and the audio master clocks to generate the bit clock.

The MCLK and BCLK source options appear in the following figure.

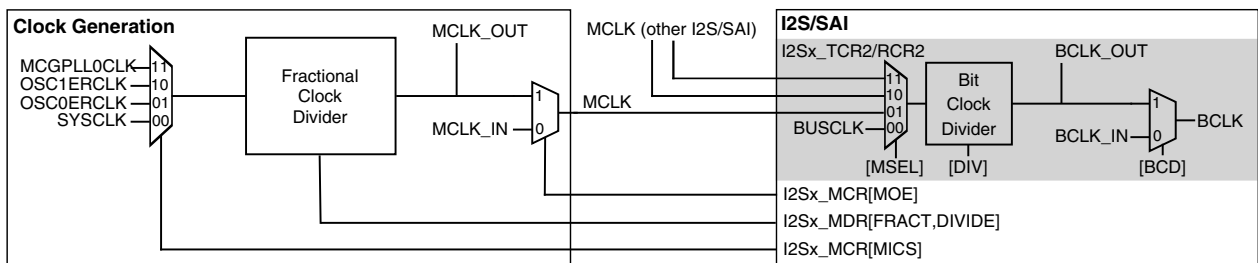

Figure 5-12. I<sup>2</sup>S/SAI clock generation

### 5.7.14 TSI clocking

In active mode, the TSI can be clocked as shown in the following figure.

**Figure 5-13. TSI clock generation**

In low-power mode, the TSI can be clocked as shown in the following figure.

**NOTE**

In the TSI chapter, these two clocks are referred to as LPOCLK and VLPOSCCLK.

**Figure 5-14. TSI low-power clock generation**

# Chapter 6

## Reset and Boot

### 6.1 Introduction

The following reset sources are supported in this MCU:

**Table 6-1. Reset sources**

| Reset sources | Description  |
|---------------|--|
| POR reset     | <ul style="list-style-type: none"> <li>• Power-on reset (POR)</li> </ul>   |
| System resets | <ul style="list-style-type: none"> <li>• External pin reset (PIN)</li> <li>• Low-voltage detect (LVD)</li> <li>• Computer operating properly (COP) watchdog reset</li> <li>• Low leakage wakeup (LLWU) reset</li> <li>• Multipurpose clock generator loss of clock (LOC) reset</li> <li>• Stop mode acknowledge error (SACKERR)</li> <li>• Software reset (SW)</li> <li>• Lockup reset (LOCKUP)</li> <li>• EzPort reset</li> <li>• MDM DAP system reset</li> </ul> |
| Debug reset   | <ul style="list-style-type: none"> <li>• JTAG reset</li> <li>• nTRST reset</li> </ul>  |

Each of the system reset sources has an associated bit in the system reset status (SRS) registers. See the [Reset Control Module](#) for register details.

The MCU exits reset in functional mode that is controlled by  $\overline{\text{EZP\_CS}}$  pin to select between the single chip (default) or serial flash programming (EzPort) modes. See [Boot options](#) for more details.

### 6.2 Reset

This section discusses basic reset mechanisms and sources. Some modules that cause resets can be configured to cause interrupts instead. Consult the individual peripheral chapters for more information.

## 6.2.1 Power-on reset (POR)

When power is initially applied to the MCU or when the supply voltage drops below the power-on reset re-arm voltage level ( $V_{POR}$ ), the POR circuit causes a POR reset condition.

As the supply voltage rises, the LVD circuit holds the MCU in reset until the supply has risen above the LVD low threshold ( $V_{LVDL}$ ). The POR and LVD bits in SRS0 register are set following a POR.

## 6.2.2 System reset sources

Resetting the MCU provides a way to start processing from a known set of initial conditions. System reset begins with the on-chip regulator in full regulation and system clocking generation from an internal reference. When the processor exits reset, it performs the following:

- Reads the start SP (SP\_main) from vector-table offset 0
- Reads the start PC from vector-table offset 4
- LR is set to 0xFFFF\_FFFF

The on-chip peripheral modules are disabled and the non-analog I/O pins are initially configured as disabled. The pins with analog functions assigned to them default to their analog function after reset.

During and following a reset, the JTAG pins have their associated input pins configured as:

- TDI in pull-up (PU)
- TCK in pull-down (PD)
- TMS in PU

and associated output pin configured as:

- TDO with no pull-down or pull-up

Note that the nTRST signal is initially configured as disabled, however once configured to its JTAG functionality its associated input pin is configured as:

- nTRST in PU

### 6.2.2.1 External pin reset (PIN)

On this device,  $\overline{\text{RESET}}$  is a dedicated pin. This pin is open drain and has an internal pullup device. Asserting  $\overline{\text{RESET}}$  wakes the device from any mode. During a pin reset, the RCM's SRS0[PIN] bit is set.

#### 6.2.2.1.1 Reset pin filter

The  $\overline{\text{RESET}}$  pin filter supports filtering from both the 1 kHz LPO clock and the bus clock. A separate filter is implemented for each clock source. In stop and VLPS mode operation, this logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected. In low leakage stop modes, a separate LPO filter in the LLWU can continue filtering the  $\overline{\text{RESET}}$  pin.

The RPF0[RSTFLTSS], RPF0[RSTFLTSRW], and RPF0[RSTFLTSEL] fields in the reset control (RCM) register set control this functionality; see the RCM chapter. The filters are asynchronously reset by Chip POR. The reset value for each filter assumes the  $\overline{\text{RESET}}$  pin is negated.

The two clock options for the  $\overline{\text{RESET}}$  pin filter when the chip is not in low leakage modes are the LPO (1 kHz) and bus clock. For low leakage modes VLLS3, VLLS2, VLLS1, the LLWU provides control (in the LLWU\_RST register) of an optional fixed digital filter running the LPO.

The LPO filter has a fixed filter value of 3. Due to a synchronizer on the input data, there is also some associated latency (2 cycles). As a result, 5 cycles are required to complete a transition from low to high or high to low.

The bus filter initializes to off (logic 1) when the bus filter is not enabled. The bus clock is used when the filter selects bus clock, and the number of counts is controlled by the RCM's RPF0[RSTFLTSEL] field.

### 6.2.2.2 Low-voltage detect (LVD)

The chip includes a system for managing low voltage conditions to protect memory contents and control MCU system states during supply voltage variations. The system consists of a power-on reset (POR) circuit and an LVD circuit with a user-selectable trip voltage. The LVD system is always enabled in normal run, wait, or stop mode. The LVD system is disabled when entering VLPx, LLS, or VLLSx modes.

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting the PMC's LVDSC1[LVDRE] bit to 1. The low voltage detection threshold is determined by the PMC's LVDSC1[LVDV] field. After an LVD reset has occurred, the

LVD system holds the MCU in reset until the supply voltage has risen above the low voltage detection threshold. The RCM's SRS0[LVD] bit is set following either an LVD reset or POR.

### 6.2.2.3 Computer operating properly (COP) watchdog timer

The computer operating properly (COP) watchdog timer (WDOG) monitors the operation of the system by expecting periodic communication from the software. This communication is generally known as servicing (or refreshing) the COP watchdog. If this periodic refreshing does not occur, the watchdog issues a system reset. The COP reset causes the RCM's SRS0[WDOG] bit to set.

### 6.2.2.4 Low leakage wakeup (LLWU)

The LLWU module provides the means for a number of external pins, the  $\overline{\text{RESET}}$  pin, and a number of internal peripherals to wake the MCU from low leakage power modes. The LLWU module is functional only in low leakage power modes.

- In LLS mode, only the  $\overline{\text{RESET}}$  pin via the LLWU can generate a system reset.
- In VLLSx modes, all enabled inputs to the LLWU can generate a system reset.

After a system reset, the LLWU retains the flags indicating the input source of the last wakeup until the user clears them.

#### NOTE

Some flags are cleared in the LLWU and some flags are required to be cleared in the peripheral module. Refer to the individual peripheral chapters for more information.

### 6.2.2.5 Multipurpose clock generator loss-of-clock (LOC)

The MCG module supports an external reference clock.

If the C6[CME] bit in the MCG module is set, the clock monitor is enabled. If the external reference falls below  $f_{\text{loc\_low}}$  or  $f_{\text{loc\_high}}$ , as controlled by the C2[RANGE] field in the MCG module, the MCU resets. The RCM's SRS0[LOC] bit is set to indicate this reset source.

**NOTE**

To prevent unexpected loss of clock reset events, all clock monitors should be disabled before entering any low power modes, including VLPR and VLPW.

**6.2.2.6 Stop mode acknowledge error (SACKERR)**

This reset is generated if the core attempts to enter stop mode, but not all modules acknowledge stop mode within 1025 cycles of the 1 kHz LPO clock.

A module might not acknowledge the entry to stop mode if an error condition occurs. The error can be caused by a failure of an external clock input to a module.

**6.2.2.7 Software reset (SW)**

The SYSRESETREQ bit in the NVIC application interrupt and reset control register can be set to force a software reset on the device. (See ARM's NVIC documentation for the full description of the register fields, especially the VECTKEY field requirements.)

Setting SYSRESETREQ generates a software reset request. This reset forces a system reset of all major components except for the debug module. A software reset causes the RCM's SRS1[SW] bit to set.

**6.2.2.8 Lockup reset (LOCKUP)**

The LOCKUP gives immediate indication of seriously errant kernel software. This is the result of the core being locked because of an unrecoverable exception following the activation of the processor's built in system state protection hardware.

The LOCKUP condition causes a system reset and also causes the RCM's SRS1[LOCKUP] bit to set.

**6.2.2.9 Tamper detect reset (TAMPER)**

A tamper detect condition can optionally cause a system reset and also causes the RCM's SRS1[TAMPER] bit to set.

### 6.2.2.10 EzPort reset

The EzPort supports a system reset request via EzPort signaling. The EzPort generates a system reset request following execution of a Reset Chip (RESET) command via the EzPort interface. This method of reset allows the chip to boot from flash memory after it has been programmed by an external source. The EzPort is enabled or disabled by the `EZP_CS` pin.

An EzPort reset causes the RCM's `SRS1[EZPT]` bit to set.

### 6.2.2.11 MDM-AP system reset request

Set the system reset request bit in the MDM-AP control register to initiate a system reset. This is the primary method for resets via the JTAG/SWD interface. The system reset is held until this bit is cleared.

Set the core hold reset bit in the MDM-AP control register to hold the core in reset as the rest of the chip comes out of system reset.

## 6.2.3 MCU Resets

A variety of resets are generated by the MCU to reset different modules.

### 6.2.3.1 VBAT POR

The VBAT POR asserts on a VBAT POR reset source. It affects only the modules within the VBAT power domain: RTC, DryIce, and VBAT Register File. These modules are not affected by the other reset types.

### 6.2.3.2 POR Only

The POR Only reset asserts on the POR reset source only. It resets the PMC and System Register File.

The POR Only reset also causes all other reset types (except VBAT POR) to occur.

### 6.2.3.3 Chip POR not VLLS

The Chip POR not VLLS reset asserts on POR and LVD reset sources. It resets parts of the SMC and SIM. It also resets the LPTMR.

The Chip POR not VLLS reset also causes these resets to occur: Chip POR, Chip Reset not VLLS, and Chip Reset (including Early Chip Reset).

### 6.2.3.4 Chip POR

The Chip POR asserts on POR, LVD, and VLLS Wakeup reset sources. It resets the Reset Pin Filter registers and parts of the SIM and MCG.

The Chip POR also causes the Chip Reset (including Early Chip Reset) to occur.

### 6.2.3.5 Chip Reset not VLLS

The Chip Reset not VLLS reset asserts on all reset sources except a VLLS Wakeup that does not occur via the  $\overline{\text{RESET}}$  pin. It resets parts of the SMC, LLWU, and other modules that remain powered during VLLS mode.

The Chip Reset not VLLS reset also causes the Chip Reset (including Early Chip Reset) to occur.

### 6.2.3.6 Early Chip Reset

The Early Chip Reset asserts on all reset sources. It resets only the flash memory module. It negates before flash memory initialization begins ("earlier" than when the Chip Reset negates).

### 6.2.3.7 Chip Reset

Chip Reset asserts on all reset sources and only negates after flash initialization has completed and the  $\overline{\text{RESET}}$  pin has also negated. It resets the remaining modules (the modules not reset by other reset types).

## 6.2.4 Reset Pin

For all reset sources except a VLLS Wakeup that does not occur via the  $\overline{\text{RESET}}$  pin, the  $\overline{\text{RESET}}$  pin is driven low by the MCU for at least 128 bus clock cycles and until flash initialization has completed.

After flash initialization has completed, the  $\overline{\text{RESET}}$  pin is released, and the internal Chip Reset negates after the  $\overline{\text{RESET}}$  pin is pulled high. Keeping the  $\overline{\text{RESET}}$  pin asserted externally delays the negation of the internal Chip Reset.

## 6.2.5 Debug resets

The following sections detail the debug resets available on the device.

### 6.2.5.1 JTAG reset

The JTAG module generate a system reset when certain IR codes are selected. This functional reset is asserted when EzPort, EXTEST, HIGHZ and CLAMP instructions are active. The reset source from the JTAG module is released when any other IR code is selected. A JTAG reset causes the RCM's SRS1[JTAG] bit to set.

### 6.2.5.2 nTRST reset

The nTRST pin causes a reset of the JTAG logic when asserted. Asserting the nTRST pin allows the debugger to gain control of the TAP controller state machine (after exiting LLS or VLLSx) without resetting the state of the debug modules.

The nTRST pin does not cause a system reset.

### 6.2.5.3 Resetting the Debug subsystem

Use the CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register to reset the debug modules. However, as explained below, using the CDBGRSTREQ bit does not reset all debug-related registers.

CDBGRSTREQ resets the debug-related registers within the following modules:

- SWJ-DP
- AHB-AP
- ETM

- ATB replicators
- ATB upsizers
- ATB funnels
- ETB
- TPIU
- MDM-AP (MDM control and status registers)
- MCM (ETB “Almost Full” logic)

CDBGRESTREQ does not reset the debug-related registers within the following modules:

- CM4 core (core debug registers: DHCSR, DCRSR, DCRDR, DEMCR)
- FPB
- DWT
- ITM
- NVIC
- Crossbar bus switch<sup>1</sup>
- AHB-AP<sup>1</sup>
- Private peripheral bus<sup>1</sup>

## 6.3 Boot

This section describes the boot sequence, including sources and options.

### 6.3.1 Boot sources

This device only supports booting from internal flash. Any secondary boot must go through an initialization sequence in flash.

### 6.3.2 Boot options

The device's functional mode is controlled by the state of the EzPort chip select ( $\overline{\text{EZP\_CS}}$ ) pin during reset.

---

1. CDBGRESTREQ does not affect AHB resources so that debug resources on the private peripheral bus are available during System Reset.

The device can be in single chip (default) or serial flash programming mode (EzPort). While in single chip mode the device can be in run or various low power modes mentioned in [Power mode transitions](#).

**Table 6-2. Mode select decoding**

| EzPort chip select (EzP_CS) | Description                            |
|-----------------------------|--|
| 0                           | Serial flash programming mode (EzPort) |
| 1                           | Single chip (default)                  |

### 6.3.3 FOPT boot options

The flash option register (FOPT) in the flash memory module allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's option byte in the flash configuration field. The user can reprogram the option byte in flash to change the FOPT values that are used for subsequent resets. For more details on programming the option byte, refer to the flash memory chapter.

The MCU uses the FOPT register bits to configure the device at reset as shown in the following table.

**Table 6-3. Flash Option Register Bit Definitions**

| Bit Num | Field      | Value | Definition  |
|---------|------------|-------|---|
| 7-2     | Reserved   |       | Reserved for future expansion.  |
| 1       | EZPORT_DIS |       | Enable/disable EzPort function.   |
|         |            | 0     | EzPort operation is disabled. The device always boots to normal CPU execution and the state of $\overline{\text{EZP\_CS}}$ signal during reset is ignored. This option avoids inadvertent resets into EzPort mode if the $\overline{\text{EZP\_CS}}$ /NMI pin is used for its NMI function. |
|         |            | 1     | EzPort operation is enabled. The state of $\overline{\text{EZP\_CS}}$ pin during reset determines if device enters EzPort mode.   |

*Table continues on the next page...*

**Table 6-3. Flash Option Register Bit Definitions (continued)**

| Bit Num | Field  | Value | Definition  |
|---------|--------|-------|---|
| 0       | LPBOOT |       | Control the reset value of OUTDIVx values in SIM_CLKDIV1 register. Larger divide value selections produce lower average power consumption during POR, VLLSx recoveries and reset sequencing and after reset exit.   |
|         |        | 0     | Low-power boot: OUTDIVx values in SIM_CLKDIV1 register are auto-configured at reset exit for higher divide values that produce lower power consumption at reset exit. <ul style="list-style-type: none"> <li>• Core and system clock divider (OUTDIV1) and bus clock divider (OUTDIV2) are 0x7 (divide by 8)</li> <li>• Flash clock divider (OUTDIV4) and FlexBus clock divider (OUTDIV3) are 0xF (divide by 16)</li> </ul>     |
|         |        | 1     | Normal boot: OUTDIVx values in SIM_CLKDIV1 register are auto-configured at reset exit for higher frequency values that produce faster operating frequencies at reset exit. <ul style="list-style-type: none"> <li>• Core and system clock divider (OUTDIV1) and bus clock divider (OUTDIV2) are 0x0 (divide by 1)</li> <li>• Flash clock divider (OUTDIV4) and FlexBus clock divider (OUTDIV3) are 0x1 (divide by 2)</li> </ul> |

### 6.3.4 Boot sequence

At power up, the on-chip regulator holds the system in a POR state until the input supply is above the POR threshold. The system continues to be held in this static state until the internally regulated supplies have reached a safe operating voltage as determined by the LVD. The Mode Controller reset logic then controls a sequence to exit reset.

1. A system reset is held on internal logic, the  $\overline{\text{RESET}}$  pin is driven out low, and the MCG is enabled in its default clocking mode.
2. Required clocks are enabled (Core Clock, System Clock, Flash Clock, and any Bus Clocks that do not have clock gate control).
3. The system reset on internal logic continues to be held, but the Flash Controller is released from reset and begins initialization operation while the Mode Control logic continues to drive the  $\overline{\text{RESET}}$  pin out low for a count of ~128 Bus Clock cycles.
4. The  $\overline{\text{RESET}}$  pin is released, but the system reset of internal logic continues to be held until the Flash Controller finishes initialization. EzPort mode is selected instead of the normal CPU execution if  $\overline{\text{EZP\_CS}}$  is low when the internal reset is deasserted. EzPort mode can be disabled by programming the FOPT[EZPORT\_DIS] field in the Flash Memory module.
5. When Flash Initialization completes, the  $\overline{\text{RESET}}$  pin is observed. If  $\overline{\text{RESET}}$  continues to be asserted (an indication of a slow rise time on the  $\overline{\text{RESET}}$  pin or external drive in low), the system continues to be held in reset. Once the  $\overline{\text{RESET}}$  pin is detected high, the system is released from reset.

6. At release of system reset, clocking is switched to a slow clock if the FOPT[LPBOOT] field in the Flash Memory module is configured for Low Power Boot
7. When the system exits reset, the processor sets up the stack, program counter (PC), and link register (LR). The processor reads the start SP (SP\_main) from vector-table offset 0. The core reads the start PC from vector-table offset 4. LR is set to 0xFFFF\_FFFF. What happens next depends on the NMI input and the FOPT[NMI\_DIS] field in the Flash Memory module:
  - If the NMI input is high or the NMI function is disabled in the NMI\_DIS field, the CPU begins execution at the PC location.
  - If the NMI input is low and the NMI function is enabled in the NMI\_DIS field, this results in an NMI interrupt. The processor executes an Exception Entry and reads the NMI interrupt handler address from vector-table offset 8. The CPU begins execution at the NMI interrupt handler.
8. If FlexNVM is enabled, the flash controller continues to restore the FlexNVM data. This data is not available immediately out of reset and the system should not access this data until the flash controller completes this initialization step as indicated by the EEERDY flag.

Subsequent system resets follow this reset flow beginning with the step where system clocks are enabled.

# Chapter 7

## Power Management

### 7.1 Introduction

This chapter describes the various chip power modes and functionality of the individual modules in these modes.

### 7.2 Power Modes Description

The power management controller (PMC) provides multiple power options to allow the user to optimize power consumption for the level of functionality needed.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. The following table compares the various power modes available.

For Run and VLPR mode there is a corresponding wait and stop mode. Wait modes are similar to ARM sleep modes. Stop modes (VLPS, STOP) are similar to ARM sleep deep mode. The very low power run (VLPR) operating mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The three primary modes of operation are run, wait and stop. The WFI instruction invokes both wait and stop modes for the chip. The primary modes are augmented in a number of ways to provide lower power based on application needs.

**Table 7-1. Chip power modes**

| Chip mode  | Description   | Core mode | Normal recovery method |
|------------|---|-----------|------------------------|
| Normal run | Allows maximum performance of chip. Default mode out of reset; on-chip voltage regulator is on. | Run       | -                      |

*Table continues on the next page...*

**Table 7-1. Chip power modes (continued)**

| Chip mode                           | Description   | Core mode  | Normal recovery method        |
|-------------------------------------|---|------------|-------------------------------|
| Normal Wait - via WFI               | Allows peripherals to function while the core is in sleep mode, reducing power. NVIC remains sensitive to interrupts; peripherals continue to be clocked.   | Sleep      | Interrupt                     |
| Normal Stop - via WFI               | Places chip in static state. Lowest power mode that retains all registers while maintaining LVD protection. NVIC is disabled; AWIC is used to wake up from interrupt; peripheral clocks are stopped.  | Sleep Deep | Interrupt                     |
| VLPR (Very Low Power Run)           | On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. Reduced frequency Flash access mode (1 MHz); LVD off; internal oscillator provides a low power 4 MHz source for the core, the bus and the peripheral clocks.   | Run        | Interrupt                     |
| VLPW (Very Low Power Wait) -via WFI | Same as VLPR but with the core in sleep mode to further reduce power; NVIC remains sensitive to interrupts (FCLK = ON). On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency.  | Sleep      | Interrupt                     |
| VLPS (Very Low Power Stop)-via WFI  | Places chip in static state with LVD operation off. Lowest power mode with ADC and pin interrupts functional. Peripheral clocks are stopped, but LPTimer, RTC, CMP, TSI, DAC can be used. NVIC is disabled (FCLK = OFF); AWIC is used to wake up from interrupt. On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. All SRAM is operating (content retained and I/O states held). | Sleep Deep | Interrupt                     |
| LLS (Low Leakage Stop)              | State retention power mode. Most peripherals are in state retention mode (with clocks stopped), but LLWU, LPTimer, RTC, CMP, TSI, DAC can be used. NVIC is disabled; LLWU is used to wake up.<br><br><b>NOTE:</b> The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit stop mode on an LLS recovery.<br>All SRAM is operating (content retained and I/O states held).             | Sleep Deep | Wakeup Interrupt <sup>1</sup> |
| VLLS3 (Very Low Leakage Stop3)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, RTC, CMP, TSI, DAC can be used. NVIC is disabled; LLWU is used to wake up.<br><br>SRAM_U and SRAM_L remain powered on (content retained and I/O states held).   | Sleep Deep | Wakeup Reset <sup>2</sup>     |
| VLLS2 (Very Low Leakage Stop2)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, RTC, CMP, TSI, DAC can be used. NVIC is disabled; LLWU is used to wake up.<br><br>SRAM_L is powered off. A portion of SRAM_U remains powered on (content retained and I/O states held).   | Sleep Deep | Wakeup Reset <sup>2</sup>     |
| VLLS1 (Very Low Leakage Stop1)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, RTC, CMP, TSI, DAC can be used. NVIC is disabled; LLWU is used to wake up.<br><br>All of SRAM_U and SRAM_L are powered off. The 32-byte system register file and the 32-byte VBAT register file remain powered for customer-critical data.  | Sleep Deep | Wakeup Reset <sup>2</sup>     |

Table continues on the next page...

**Table 7-1. Chip power modes (continued)**

| Chip mode                 | Description  | Core mode | Normal recovery method |
|---------------------------|--|-----------|------------------------|
| BAT (backup battery only) | The chip is powered down except for the VBAT supply. The RTC and the 32-byte VBAT register file for customer-critical data remain powered. | Off       | Power-up Sequence      |

1. Resumes normal run mode operation by executing the LLWU interrupt service routine.
2. Follows the reset flow with the LLWU interrupt flag set for the NVIC.

## 7.3 Entering and exiting power modes

The WFI instruction invokes wait and stop modes for the chip. The processor exits the low-power mode via an interrupt. The [Nested Vectored Interrupt Controller \(NVIC\)](#) describes interrupt operation and what peripherals can cause interrupts.

### NOTE

The WFE instruction can have the side effect of entering a low-power mode, but that is not its intended usage. See ARM documentation for more on the WFE instruction.

Recovery from VLLSx is through the wake-up Reset event. The chip wake-ups from VLLSx by means of reset, an enabled pin or enabled module. See the table "LLWU inputs" in the LLWU configuration section for a list of the sources.

The wake-up flow from VLLSx is through reset. The wakeup bit in the SRS registers in the RCM is set indicating that the chip is recovering from a low power mode. Code execution begins; however, the I/O pins are held in their pre low power mode entry states, and the system oscillator and MCG registers are reset (even if EREFSTEN had been set before entering VLLSx). Software must clear this hold by writing a 1 to the ACKISO bit in the Regulator Status and Control Register in the PMC module.

### NOTE

To avoid unwanted transitions on the pins, software must re-initialize the I/O pins to their pre-low-power mode entry states *before* releasing the hold.

If the oscillator was configured to continue running during VLLSx modes, it must be re-configured before the ACKISO bit is cleared. The oscillator configuration within the MCG is cleared after VLLSx recovery and the oscillator will stop when ACKISO is cleared unless the register is re-configured.

## 7.4 Power mode transitions

The following figure shows the power mode transitions. Any reset always brings the chip back to the normal run state. In run, wait, and stop modes active power regulation is enabled. The VLPx modes offer a lower power operating mode than normal modes. VLPR and VLPW are limited in frequency. The LLS and VLLSx modes are the lowest power stop modes based on amount of logic or memory that is required to be retained by the application.

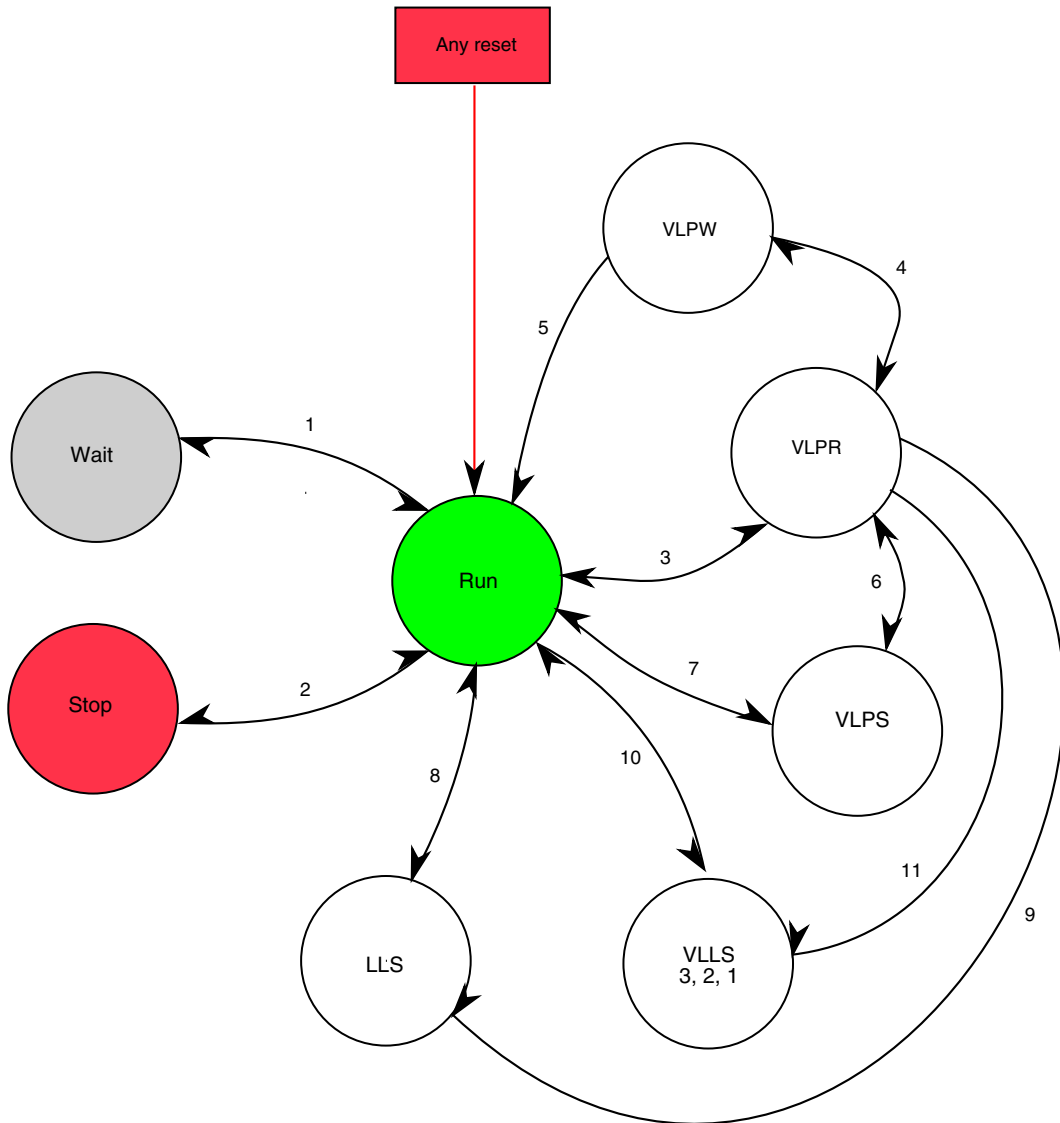

Figure 7-1. Power mode state transition diagram

## 7.5 Power modes shutdown sequencing

When entering stop or other low-power modes, the clocks are shut off in an orderly sequence to safely place the chip in the targeted low-power state. All low-power entry sequences are initiated by the core executing an WFI instruction. The ARM core's outputs, SLEEPDEEP and SLEEPING, trigger entry to the various low-power modes:

- System level wait and VLPW modes equate to: SLEEPING &  $\overline{\text{SLEEPDEEP}}$
- All other low power modes equate to: SLEEPING & SLEEPDEEP

When entering the non-wait modes, the chip performs the following sequence:

- Shuts off Core Clock and System Clock to the ARM Cortex-M4 core immediately.
- Polls stop acknowledge indications from the non-core crossbar masters (DMA, Ethernet), supporting peripherals (SPI, PIT, RNG) and the Flash Controller for indications that System Clocks, Bus Clock and/or Flash Clock need to be left enabled to complete a previously initiated operation, effectively stalling entry to the targeted low power mode. When all acknowledges are detected, System Clock, Bus Clock and Flash Clock are turned off at the same time.
- MCG and Mode Controller shut off clock sources and/or the internal supplies driven from the on-chip regulator as defined for the targeted low power mode.

In wait modes, most of the system clocks are not affected by the low power mode entry. The Core Clock to the ARM Cortex-M4 core is shut off. Some modules support stop-in-wait functionality and have their clocks disabled under these configurations.

The debugger modules support a transition from stop, wait, VLPS, and VLPW back to a halted state when the debugger is enabled. This transition is initiated by setting the Debug Request bit in MDM-AP control register. As part of this transition, system clocking is re-established and is equivalent to normal run/VLPR mode clocking configuration.

## 7.6 Module Operation in Low Power Modes

The following table illustrates the functionality of each module while the chip is in each of the low power modes. (Debug modules are discussed separately; see [Debug in Low Power Modes](#).) Number ratings (such as 2 MHz and 1 Mbit/s) represent the maximum frequencies or maximum data rates per mode. Also, these terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.

## Module Operation in Low Power Modes

- powered = Memory is powered to retain contents.
- low power = Flash has a low power state that retains configuration registers to support faster wakeup.
- OFF = Modules are powered off; module is in reset state upon wakeup.
- wakeup = Modules can serve as a wakeup source for the chip.

**Table 7-2. Module operation in low power modes**

| Modules                             | Stop  | VLPR                          | VLPW                          | VLPS                          | LLS                            | VLLSx                               |
|-------------------------------------|---|-------------------------------|-------------------------------|-------------------------------|--------------------------------|-------------------------------------|
| <b>Core modules</b>                 |   |                               |                               |                               |                                |                                     |
| NVIC                                | static  | FF                            | FF                            | static                        | static                         | OFF                                 |
| <b>System modules</b>               |   |                               |                               |                               |                                |                                     |
| Mode Controller                     | FF  | FF                            | FF                            | FF                            | FF                             | FF                                  |
| LLWU <sup>1</sup>                   | static  | static                        | static                        | static                        | FF                             | FF                                  |
| Regulator                           | ON  | low power                     | low power                     | low power                     | low power                      | low power                           |
| LVD                                 | ON  | disabled                      | disabled                      | disabled                      | disabled                       | disabled                            |
| Brown-out Detection                 | ON  | ON                            | ON                            | ON                            | ON                             | ON                                  |
| DMA                                 | static  | FF                            | FF                            | static                        | static                         | OFF                                 |

- Using the LLWU module, the external pins available for this chip do not require the associated peripheral function to be enabled. It only requires the function controlling the pin (GPIO or peripheral) to be configured as an input to allow a transition to occur to the LLWU.
- A 16 KB portion of SRAM\_U block is left powered on in low power mode VLLS2.
- FlexRAM enabled as EEPROM is not writable in VLPR and writes are ignored. Read accesses to FlexRAM as EEPROM while in VLPR are allowed. There are no access restrictions for FlexRAM configured as traditional RAM.
- These components remain powered in BAT power mode.
- Use an externally generated bit clock or an externally generated audio master clock (including EXTAL).
- RTC\_CLKOUT is not available.
- CMP in stop or VLPS supports high speed or low speed external pin to pin or external pin to DAC compares. CMP in LLS or VLLSx only supports low speed external pin to pin or external pin to DAC compares. Windowed, sampled & filtered modes of operation are not available while in stop, VLPS, LLS, or VLLSx modes.
- TSI wakeup from LLS and VLLSx modes is limited to a single selectable pin.

## 7.7 Clock Gating

To conserve power, the clocks to most modules can be turned off using the SCGCx registers in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module. Prior to initializing a module, set the corresponding bit in the SCGCx register to enable the clock. Before turning off the clock, make sure to disable the module. For more details, refer to the clock distribution and SIM chapters.

# Chapter 8

## Security

### 8.1 Introduction

This device implements security based on the mode selected from the flash module. The following sections provide an overview of flash security and details the effects of security on non-flash modules.

### 8.2 Flash Security

The flash module provides security information to the MCU based on the state held by the FSEC[SEC] bits. The MCU, in turn, confirms the security request and limits access to flash resources. During reset, the flash module initializes the FSEC register using data read from the security byte of the flash configuration field.

#### NOTE

The security features apply only to external accesses via debug and EzPort. CPU accesses to the flash are not affected by the status of FSEC.

In the unsecured state all flash commands are available to the programming interfaces (JTAG and EzPort), as well as user code execution of Flash Controller commands. When the flash is secured (FSEC[SEC] = 00, 01, or 11), programmer interfaces are only allowed to launch mass erase operations and have no access to memory locations.

Further information regarding the flash security options and enabling/disabling flash security is available in the [Flash Memory Module](#).

## 8.3 Security Interactions with other Modules

The flash security settings are used by the SoC to determine what resources are available. The following sections describe the interactions between modules and the flash security settings or the impact that the flash security has on non-flash modules.

### 8.3.1 Security interactions with FlexBus

When flash security is enabled, SIM\_SOPT2[FBSL] enables/disables off-chip accesses through the FlexBus interface. The FBSL bitfield also has an option to allow opcode and operand accesses or only operand accesses.

### 8.3.2 Security Interactions with EzPort

When flash security is active the MCU can still boot in EzPort mode. The EzPort holds the flash logic in NVM special mode and thus limits flash operation when flash security is active. While in EzPort mode and security is active, flash bulk erase (BE) can still be executed. The write FCCOB registers (WRFCCOB) command is limited to the mass erase (Erase All Blocks) and verify all 1s (Read 1s All Blocks) commands. Read accesses to internal memories via the EzPort are blocked when security is enabled.

The mass erase can be used to disable flash security, but all of the flash contents are lost in the process. A mass erase via the EzPort is allowed even when some memory locations are protected.

When mass erase has been disabled, mass erase via the EzPort is blocked and cannot be defeated.

### 8.3.3 Security Interactions with Debug

When flash security is active the JTAG port cannot access the memory resources of the MCU. Boundary scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read flash contents.

Although most debug functions are disabled, the debugger can write to the Flash Mass Erase in Progress bit in the MDM-AP Control register to trigger a mass erase (Erase All Blocks) command. A mass erase via the debugger is allowed even when some memory locations are protected.

When mass erase is disabled, mass erase via the debugger is blocked.

# Chapter 9

## Debug

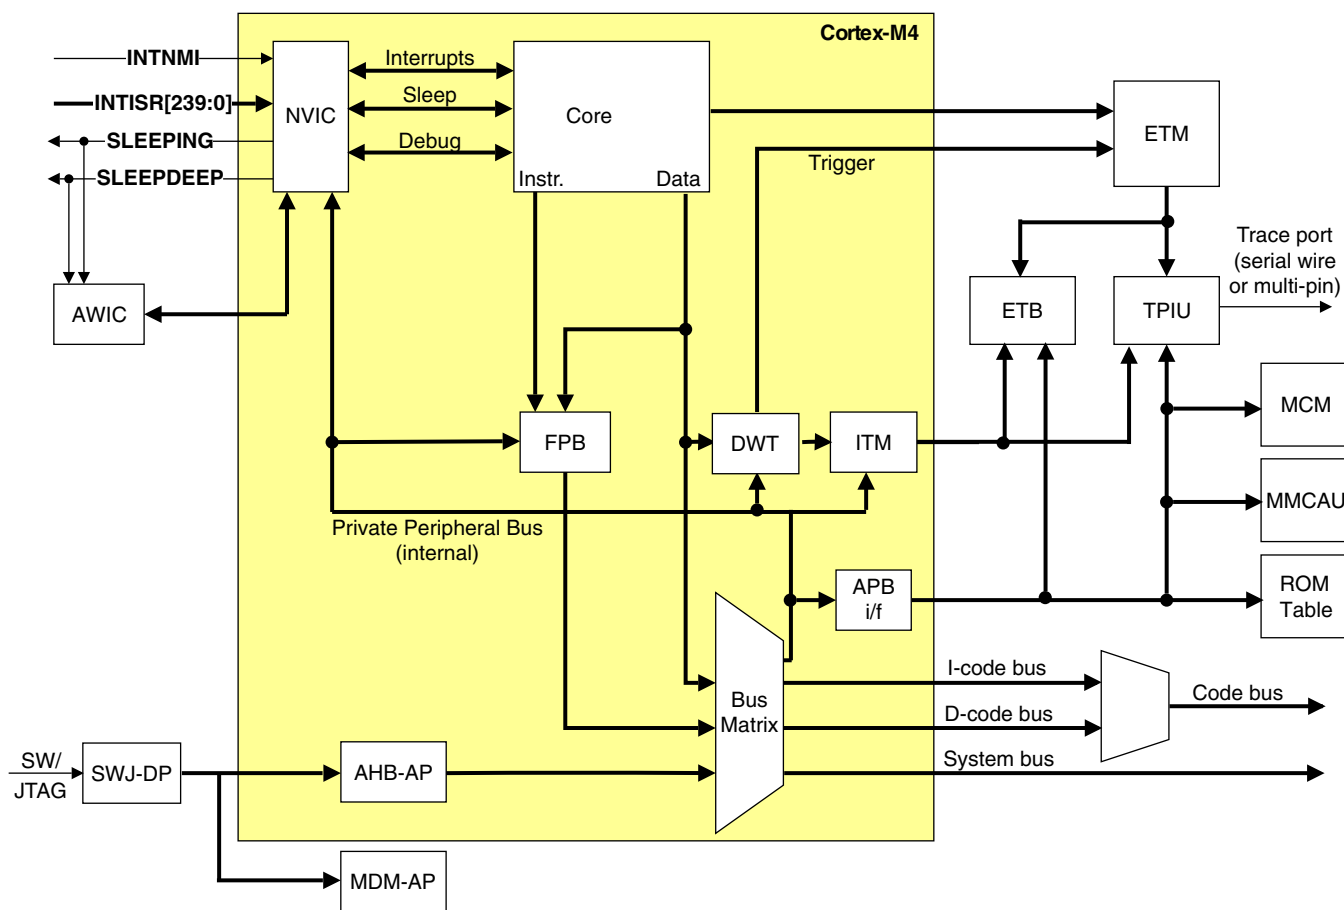

### 9.1 Introduction

This device's debug is based on the ARM coresight architecture and is configured in each device to provide the maximum flexibility as allowed by the restrictions of the pinout and other available resources.

Four debug interfaces are supported:

- IEEE 1149.1 JTAG
- IEEE 1149.7 JTAG (cJTAG)
- Serial Wire Debug (SWD)
- ARM Real-Time Trace Interface

The basic Cortex-M4 debug architecture is very flexible. The following diagram shows the topology of the core debug architecture and its components.

**Figure 9-1. Cortex-M4 Debug Topology**

The following table presents a brief description of each one of the debug components.

**Table 9-1. Debug Components Description**

| Module   | Description  |
|--|--|
| SWJ-DP+ cJTAG                                    | Modified Debug Port with support for SWD, JTAG, cJTAG  |
| AHB-AP   | AHB Master Interface from JTAG to debug module and SOC system memory maps  |
| MDM-AP   | Provides centralized control and status registers for an external debugger to control the device.                |
| ROM Table  | Identifies which debug IP is available.  |
| Core Debug                                       | Singlestep, Register Access, Run, Core Status  |
| CoreSight Trace Funnel (not shown in figure)     | The CSTF combines multiple trace streams onto a single ATB bus.  |
| CoreSight Trace Replicator (not shown in figure) | The ATB replicator enables two trace sinks to be wired together and operate from the same incoming trace stream. |
| ETM (Embedded Trace Macrocell)                   | ETMv3.5 Architecture   |
| CoreSight ETB (Embedded Trace Buffer)            | Memory mapped buffer used to store trace data.   |
| ITM  | S/W Instrumentation Messaging + Simple Data Trace Messaging + Watchpoint Messaging                               |

Table continues on the next page...

**Table 9-1. Debug Components Description (continued)**

| Module                             | Description  |
|------------------------------------|--|
| DWT (Data and Address Watchpoints) | 4 data and address watchpoints   |
| FPB (Flash Patch and Breakpoints)  | <p>The FPB implements hardware breakpoints and patches code and data from code space to system space.</p> <p>The FPB unit contains two literal comparators for matching against literal loads from Code space, and remapping to a corresponding area in System space.</p> <p>The FBP also contains six instruction comparators for matching against instruction fetches from Code space, and remapping to a corresponding area in System space. Alternatively, the six instruction comparators can individually configure the comparators to return a Breakpoint Instruction (BKPT) to the processor core on a match, so providing hardware breakpoint capability.</p> |
| TPIU (Trace Port Interface Unit)   | <p>Synchronous Mode (5-pin) = TRACE_D[3:0] + TRACE_CLKOUT</p> <p>Synchronous Mode (3-pin) = TRACE_D[1:0] + TRACE_CLKOUT</p> <p>Asynchronous Mode (1-pin) = TRACE_SWO (available on JTAG_TDO)</p>   |
| MCM (Miscellaneous Control Module) | The MCM provides miscellaneous control functions including control of the ETB and trace path switching.  |

## 9.2 The Debug Port

The configuration of the cJTAG module, JTAG controller, and debug port is illustrated in the following figure:

**Figure 9-2. Modified Debug Port**

The debug port comes out of reset in standard JTAG mode and is switched into either cJTAG or SWD mode by the following sequences. Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions.

### 9.2.1 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111\_1001\_1110\_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

#### NOTE

See the ARM documentation for the CoreSight DAP Lite for restrictions.

### 9.2.2 JTAG-to-cJTAG change sequence

1. Reset the debug port

2. Set the control level to 2 via zero-bit scans
3. Execute the Store Format (STFMT) command (00011) to set the scan format register to 1149.7 scan format

## 9.3 Debug Port Pin Descriptions

The debug port pins default after POR to their JTAG functionality with the exception of JTAG\_TRST\_b and can be later reassigned to their alternate functionalities. In cJTAG and SWD modes JTAG\_TDI and JTAG\_TRST\_b can be configured to alternate GPIO functions.

**Table 9-2. Debug port pins**

| Pin Name               | JTAG Debug Port |                          | cJTAG Debug Port |                                | SWD Debug Port |                                | Internal Pull-up\Down |
|------------------------|-----------------|--------------------------|------------------|--------------------------------|----------------|--------------------------------|-----------------------|

| JTAG_TMS/<br>SWD_DIO   | I/O             | JTAG Test Mode Selection | I/O              | cJTAG Data                     | I/O            | Serial Wire Data               | Pull-up               |
| JTAG_TCLK/<br>SWD_CLK  | I               | JTAG Test Clock          | I                | cJTAG Clock                    | I              | Serial Wire Clock              | Pull-down             |
| JTAG_TDI               | I               | JTAG Test Data Input     | -                | -                              | -              | -                              | Pull-up               |
| JTAG_TDO/<br>TRACE_SWO | O               | JTAG Test Data Output    | O                | Trace output over a single pin | O              | Trace output over a single pin | N/C                   |
| JTAG_TRST_b            | I               | JTAG Reset               | I                | cJTAG Reset                    | -              | -                              | Pull-up               |

## 9.4 System TAP connection

The system JTAG controller is connected in parallel to the ARM TAP controller. The system JTAG controller IR codes overlay the ARM JTAG controller IR codes without conflict. Refer to the IR codes table for a list of the available IR codes. The output of the TAPs (TDO) are muxed based on the IR code which is selected. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP. At power on reset, ARM's IDCODE (IR=4'b1110) is selected.

## 9.4.1 IR Codes

**Table 9-3. JTAG Instructions**

| Instruction            | Code[3:0]              | Instruction Summary   |
|------------------------|------------------------|---|
| IDCODE                 | 0000                   | Selects device identification register for shift  |
| SAMPLE/PRELOAD         | 0010                   | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                               |
| SAMPLE                 | 0011                   | Selects boundary scan register for shifting and sampling without disturbing functional operation  |
| EXTEST                 | 0100                   | Selects boundary scan register while applying preloaded values to output pins and asserting functional reset                                |
| HIGHZ                  | 1001                   | Selects bypass register while three-stating all output pins and asserting functional reset  |
| CLAMP                  | 1100                   | Selects bypass register while applying preloaded values to output pins and asserting functional reset                                       |
| EZPORT                 | 1101                   | Enables the EZPORT function for the SoC and asserts functional reset.   |
| ARM_IDCODE             | 1110                   | ARM JTAG-DP Instruction   |
| BYPASS                 | 1111                   | Selects bypass register for data operations   |
| Factory debug reserved | 0101, 0110, 0111       | Intended for factory debug only   |
| ARM JTAG-DP Reserved   | 1000, 1010, 1011, 1110 | These instructions will go the ARM JTAG-DP controller. Please look at ARM JTAG-DP documentation for more information on these instructions. |
| Reserved <sup>1</sup>  | All other opcodes      | Decoded to select bypass register   |

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

## 9.5 JTAG status and control registers

Through the ARM Debug Access Port (DAP), the debugger has access to the status and control elements, implemented as registers on the DAP bus as shown in the following figure. These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port (DAP) using JTAG, cJTAG, or SWD. The MDM-AP is accessible as Debug Access Port 1 with the available registers shown in the table below.

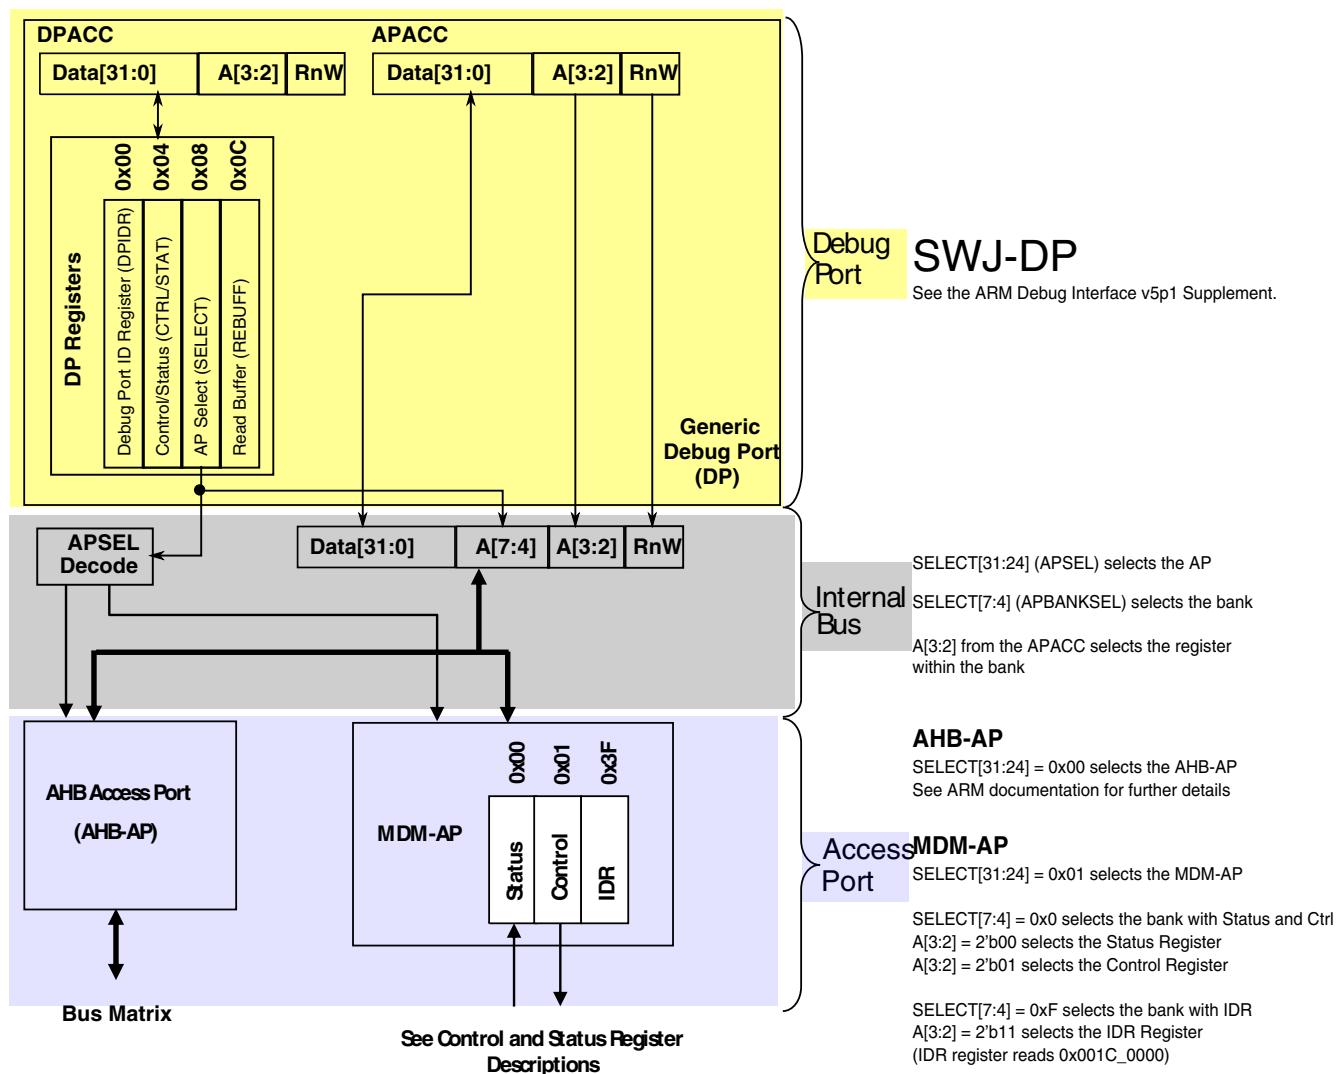

**Table 9-4. MDM-AP Register Summary**

| Address | Register | Description |
|---------|----------|-------------|
|---------|----------|-------------|

*Table continues on the next page...*

**Table 9-4. MDM-AP Register Summary (continued)**

|             |         |  |
|-------------|---------|--|
| 0x0100_0000 | Status  | See <a href="#">MDM-AP Status Register</a>                         |
| 0x0100_0004 | Control | See <a href="#">MDM-AP Control Register</a>                        |
| 0x0100_00FC | ID      | Read-only identification register that always reads as 0x001C_0000 |

**Figure 9-3. MDM AP Addressing**

## 9.5.1 MDM-AP Control Register

**Table 9-5. MDM-AP Control register assignments**

| Bit | Name                                | Secure <sup>1</sup> | Description   |
|-----|-------------------------------------|---------------------|---|
| 0   | Flash Mass Erase in Progress        | Y                   | <p>Set to cause mass erase. Cleared by hardware after mass erase operation completes.</p> <p>When mass erase is disabled (via MEEN and SEC settings), the erase request does not occur and the Flash Mass Erase in Progress bit continues to assert until the next system reset.</p>  |
| 1   | Debug Disable                       | N                   | <p>Set to disable debug. Clear to allow debug operation. When set it overrides the C_DEBUGEN bit within the DHCSR and force disables Debug logic.</p>   |
| 2   | Debug Request                       | N                   | <p>Set to force the Core to halt.</p> <p>If the Core is in a stop or wait mode, this bit can be used to wakeup the core and transition to a halted state.</p>   |
| 3   | System Reset Request                | N                   | <p>Set to force a system reset. The system remains held in reset until this bit is cleared.</p>   |
| 4   | Core Hold Reset                     | N                   | <p>Configuration bit to control Core operation at the end of system reset sequencing.</p> <p>0 Normal operation - release the Core from reset along with the rest of the system at the end of system reset sequencing.</p> <p>1 Suspend operation - hold the Core in reset at the end of reset sequencing. Once the system enters this suspended state, clearing this control bit immediately releases the Core from reset and CPU operation begins.</p>  |
| 5   | VLLSx Debug Request (VLLDBGREQ)     | N                   | <p>Set to configure the system to be held in reset after the next recovery from a VLLSx mode. This bit is ignored on a VLLS wakeup via the Reset pin. During a VLLS wakeup via the Reset pin, the system can be held in reset by holding the reset pin asserted allowing the debugger to re-initialize the debug modules.</p> <p>This bit holds the system in reset when VLLSx modes are exited to allow the debugger time to re-initialize debug IP before the debug session continues.</p> <p>The Mode Controller captures this bit logic on entry to VLLSx modes. Upon exit from VLLSx modes, the Mode Controller will hold the system in reset until VLLDBGACK is asserted.</p> <p>The VLLDBGREQ bit clears automatically due to the POR reset generated as part of the VLLSx recovery.</p> |
| 6   | VLLSx Debug Acknowledge (VLLDBGACK) | N                   | <p>Set to release a system being held in reset following a VLLSx recovery</p> <p>This bit is used by the debugger to release the system reset when it is being held on VLLSx mode exit. The debugger re-initializes all debug IP and then assert this control bit to allow the Mode Controller to release the system from reset and allow CPU operation to begin.</p> <p>The VLLDBGACK bit is cleared by the debugger or can be left set because it clears automatically due to the POR reset generated as part of the next VLLSx recovery.</p>   |

*Table continues on the next page...*

**Table 9-5. MDM-AP Control register assignments (continued)**

| Bit    | Name                          | Secure <sup>1</sup> | Description  |
|--------|-------------------------------|---------------------|--|
| 7      | LLS, VLLSx Status Acknowledge | N                   | Set this bit to acknowledge the DAP LLS and VLLS Status bits have been read. This acknowledge automatically clears the status bits.<br><br>This bit is used by the debugger to clear the sticky LLS and VLLSx mode entry status bits. This bit is asserted and cleared by the debugger.                            |
| 8      | Timestamp Disable             | N                   | Set this bit to disable the 48-bit global trace timestamp counter during debug halt mode when the core is halted.<br><br>0 The timestamp counter continues to count assuming trace is enabled and the ETM is enabled. (default)<br><br>1 The timestamp counter freezes when the core has halted (debug halt mode). |
| 9 – 31 | Reserved for future use       | N                   |  |

1. Command available in secure mode

## 9.5.2 MDM-AP Status Register

**Table 9-6. MDM-AP Status register assignments**

| Bit | Name                         | Description   |
|-----|------------------------------|---|
| 0   | Flash Mass Erase Acknowledge | The Flash Mass Erase Acknowledge bit is cleared after any system reset. The bit is also cleared at launch of a mass erase command due to write of Flash Mass Erase in Progress bit in MDM AP Control Register. The Flash Mass Erase Acknowledge is set after Flash control logic has started the mass erase operation.<br><br>When mass erase is disabled (via MEEN and SEC settings), an erase request due to setting of Flash Mass Erase in Progress bit is not acknowledged. |
| 1   | Flash Ready                  | Indicate Flash has been initialized and debugger can be configured even if system is continuing to be held in reset via the debugger.   |
| 2   | System Security              | Indicates the security state. When secure, the debugger does not have access to the system bus or any memory mapped peripherals. This bit indicates when the part is locked and no system bus access is possible.   |
| 3   | System Reset                 | Indicates the system reset state.<br><br>0 System is in reset<br><br>1 System is not in reset   |
| 4   | Reserved                     |   |
| 5   | Mass Erase Enable            | Indicates if the MCU can be mass erased or not<br><br>0 Mass erase is disabled<br><br>1 Mass erase is enabled   |

Table continues on the next page...

**Table 9-6. MDM-AP Status register assignments (continued)**

| Bit     | Name                       | Description   |
|---------|----------------------------|---|
| 6       | Backdoor Access Key Enable | Indicates if the MCU has the backdoor access key enabled.<br>0 Disabled<br>1 Enabled  |
| 7       | LP Enabled                 | Decode of LPLLSM control bits to indicate that VLPS, LLS, or VLLSx are the selected power mode the next time the ARM Core enters Deep Sleep.<br>0 Low Power Stop Mode is not enabled<br>1 Low Power Stop Mode is enabled<br><br>Usage intended for debug operation in which Run to VLPS is attempted. Per debug definition, the system actually enters the Stop state. A debugger should interpret deep sleep indication (with SLEEPDEEP and SLEEPING asserted), in conjunction with this bit asserted as the debugger-VLPS status indication.  |
| 8       | Very Low Power Mode        | Indicates current power mode is VLPx. This bit is not 'sticky' and should always represent whether VLPx is enabled or not.<br><br>This bit is used to throttle JTAG TCK frequency up/down.  |
| 9       | LLS Mode Exit              | This bit indicates an exit from LLS mode has occurred. The debugger will lose communication while the system is in LLS (including access to this register). Once communication is reestablished, this bit indicates that the system had been in LLS. Since the debug modules held their state during LLS, they do not need to be reconfigured.<br><br>This bit is set during the LLS recovery sequence. The LLS Mode Exit bit is held until the debugger has had a chance to recognize that LLS was exited and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register.                    |
| 10      | VLLSx Modes Exit           | This bit indicates an exit from VLLSx mode has occurred. The debugger will lose communication while the system is in VLLSx (including access to this register). Once communication is reestablished, this bit indicates that the system had been in VLLSx. Since the debug modules lose their state during VLLSx modes, they need to be reconfigured.<br><br>This bit is set during the VLLSx recovery sequence. The VLLSx Mode Exit bit is held until the debugger has had a chance to recognize that a VLLS mode was exited and is cleared by a write of 1 to the LLS, VLLSx Status Acknowledge bit in MDM AP Control register. |
| 11 – 15 | Reserved for future use    | Always read 0.  |
| 16      | Core Halted                | Indicates the Core has entered debug halt mode  |
| 17      | Core SLEEPDEEP             | Indicates the Core has entered a low power mode   |
| 18      | Core SLEEPING              | SLEEPING==1 and SLEEPDEEP==0 indicates wait or VLPW mode.<br>SLEEPING==1 and SLEEPDEEP==1 indicates stop or VLPS mode.  |
| 19 – 31 | Reserved for future use    | Always read 0.  |

## 9.6 Debug Resets

The debug system receives the following sources of reset:

- JTAG\_TRST\_b from an external signal. This signal is optional and may not be available in all packages.
- Debug reset (CDBG\_RSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to reset the debug logic.
- TRST asserted via the cJTAG escape command.
- System POR reset

Conversely the debug system is capable of generating system reset using the following mechanism:

- A system reset in the DAP control register which allows the debugger to hold the system in reset.
- SYSRESETREQ bit in the NVIC application interrupt and reset control register
- A system reset in the DAP control register which allows the debugger to hold the Core in reset.

## 9.7 AHB-AP

AHB-AP provides the debugger access to all memory and registers in the system, including processor registers through the NVIC. System access is independent of the processor status. AHB-AP does not do back-to-back transactions on the bus, so all transactions are non-sequential. AHB-AP can perform unaligned and bit-band transactions. AHB-AP transactions bypass the FPB, so the FPB cannot remap AHB-AP transactions. SWJ/SW-DP-initiated transaction aborts drive an AHB-AP-supported sideband signal called HAbort. This signal is driven into the Bus Matrix, which resets the Bus Matrix state, so that AHB-AP can access the Private Peripheral Bus for last ditch debugging such as read/stop/reset the core. AHB-AP transactions are little endian.

The MPU includes default settings and protections for the Region Descriptor 0 (RGD0) such that the Debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

For a short period at the start of a system reset event the system security status is being determined and debugger access to all AHB-AP transactions is blocked. The MDM-AP Status register is accessible and can be monitored to determine when this initial period is completed. After this initial period, if system reset is held via assertion of the RESET pin, the debugger has access via the bus matrix to the private peripheral bus to configure the debug IP even while system reset is asserted. While in system reset, access to other memory and register resources, accessed over the Crossbar Switch, is blocked.

## 9.8 ITM

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them.
3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.
4. Global system timestamping. Timestamps can optionally be generated using a system-wide 48-bit count value. The same count value can be used to insert timestamps in the ETM trace stream, allowing coarse-grain correlation.

## 9.9 Core Trace Connectivity

Figure 9-4. Core Trace Connectivity

The ETM and ITM can route its data to the ETB or the TPIU. (See the [MCM \(Miscellaneous Control Module\)](#) for controlling the routing to the TPIU.) This configuration enables the use of trace with low cost tools while maintaining the compatibility with trace probes. The arbitration between the ETM and ITM is performed inside the TPIU.

The ETB can not be configured with an interface smaller than 32 bits, making it necessary to add an ATB upsizer to make it compatible with the ETM operating with an 8-bit interface. The speed of the ETB 32 bit interface and its associated RAM is expected to be one quarter of the ETB clock.

The following combinations paths are supported:

1. ETM -> ETB
2. ETM -> TPIU(4 pin or 2 pin parallel)
3. ITM->ETB
4. ITM->TPIU(1 pin SWO, 2 pin or 4 pin parallel)
5. ETM & ITM -> ETB
6. ETM & ITM -> TPIU
7. ETM -> ETB & ITM -> TPIU

The following combination paths are NOT supported

1. ETM -> TPIU & ETB
2. ITM -> TPIU & ETB

## 9.10 Embedded Trace Macrocell v3.5 (ETM)

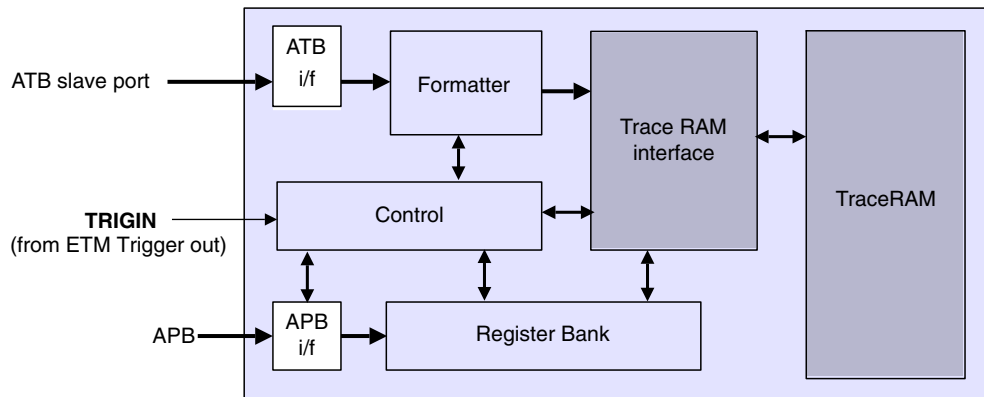

The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it either with the Cortex-M4 Trace Port Interface Unit (M4-TPIU), or with the CoreSight ETB.

The main features of an ETM are:

- tracing of 16-bit and 32-bit Thumb instructions
- four EmbeddedICE watchpoint inputs
- a Trace Start/Stop block with EmbeddedICE inputs
- one reduced function counter
- two external inputs
- a 24-byte FIFO queue
- global timestamping

## 9.11 Coresight Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from any CoreSight-compliant component trace source with an ATB master port, such as a trace source or a trace funnel. It is included in this device to remove dependencies from the trace pin pad speed, and enable low cost trace solutions. The TraceRAM size is 2 KB.

**Figure 9-5. ETB Block Diagram**

The ETB contains the following blocks:

- **Formatter** -- Inserts source ID signals into the data packet stream so that trace data can be re-associated with its trace source after the data is read back out of the ETB.
- **Control** -- Control registers for trace capture and flushing.
- **APB interface** -- Read, write, and data pointers provide access to ETB registers. In addition, the APB interface supports wait states through the use of a PREADYDBG signal output by the ETB. The APB interface is synchronous to the ATB domain.
- **Register bank** -- Contains the management, control, and status registers for triggers, flushing behavior, and external control.
- **Trace RAM interface** -- Controls reads and writes to the Trace RAM.

### 9.11.1 Performance Profiling with the ETB

To create a performance profile (e.g. gprof) for the target application, a means to collect trace over a long period of time is needed. The ETB buffer is too small to capture a meaningful profile in just one take. What is needed is to collect and concatenate data from the ETB buffer for multiple sequential runs. Using the ETB packet counter (described in [Miscellaneous Control Module \(MCM\)](#)), the trace analysis tool can capture

multiple sequential runs by executing code until the ETB is almost full, and halting or executing an interrupt handler to allow the buffer to be emptied, and then continuing executing code. The target halts or executes an interrupt handler when the buffer is almost full to empty the data and then the debugger runs the target again.

### 9.11.2 ETB Counter Control

The ETB packet counter is controlled by the ETB counter control register, ETB reload register, and ETB counter value register implemented in the [Miscellaneous Control Module \(MCM\)](#) accessible via the Private Peripheral Bus. Via the ETB counter control register the ETB control logic can be configured to cause an MCM Alert Interrupt, an NMI Interrupt, or cause a Debug halt when the down counter reaches 0. Other features of the ETB control logic include:

- Down counter to count as many as 512 x 32-bit packets.
- Reload request transfers reload value to counter.
- ATB valid and ready signals used to form counter decrement.
- The counter disarms itself when the count reaches 0.

## 9.12 TPIU

The TPIU acts as a bridge between the on-chip trace data from the Embedded Trace Macrocell (ETM) and the Instrumentation Trace Macrocell (ITM), with separate IDs, to a data stream, encapsulating IDs where required, that is then captured by a Trace Port Analyzer (TPA). The TPIU is specially designed for low-cost debug.

## 9.13 DWT

The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, an ETM trigger, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT\_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT\_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
  - Clock cycles (CYCCNT)
  - Folded instructions
  - Load store unit (LSU) operations

- Sleep cycles
- CPI (all instruction cycles except for the first cycle)
- Interrupt overhead

### NOTE

An event is emitted each time a counter overflows.

- The DWT can be configured to emit PC samples at defined intervals, and to emit interrupt event information.

## 9.14 Debug in Low Power Modes

In low power modes in which the debug modules are kept static or powered off, the debugger cannot gather any debug data for the duration of the low power mode. In the case that the debugger is held static, the debug port returns to full functionality as soon as the low power mode exits and the system returns to a state with active debug. In the case that the debugger logic is powered off, the debugger is reset on recovery and must be reconfigured once the low power mode is exited.

Power mode entry logic monitors Debug Power Up and System Power Up signals from the debug port as indications that a debugger is active. These signals can be changed in RUN, VLPR, WAIT and VLPW. If the debug signal is active and the system attempts to enter stop or VLPS, FCLK continues to run to support core register access. In these modes in which FCLK is left active the debug modules have access to core registers but not to system memory resources accessed via the crossbar.

With debug enabled, transitions from Run directly to VLPS are not allowed and result in the system entering Stop mode instead. Status bits within the MDM-AP Status register can be evaluated to determine this pseudo-VLPS state. Note with the debug enabled, transitions from Run--> VLPR --> VLPS are still possible but also result in the system entering Stop mode instead.

In VLLS mode all debug modules are powered off and reset at wakeup. In LLS mode, the debug modules retain their state but no debug activity is possible.

### NOTE

When using cJTAG and entering LLS mode, the cJTAG controller must be reset on exit from LLS mode.

Going into a VLLSx mode causes all the debug controls and settings to be reset. To give time to the debugger to sync up with the HW, the MDM-AP Control register can be configured hold the system in reset on recovery so that the debugger can regain control and reconfigure debug logic prior to the system exiting reset and resuming operation.

### 9.14.1 Debug Module State in Low Power Modes

The following table shows the state of the debug modules in low power modes. These terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.
- OFF = Modules are powered off; module is in reset state upon wakeup.

**Table 9-7. Debug Module State in Low Power Modes**

| Module     | STOP | VLPR | VLPW | VLPS | LLS    | VLLSx |
|------------|------|------|------|------|--------|-------|
| Debug Port | FF   | FF   | FF   | OFF  | static | OFF   |
| AHB-AP     | FF   | FF   | FF   | OFF  | static | OFF   |
| ITM        | FF   | FF   | FF   | OFF  | static | OFF   |
| ETM        | FF   | FF   | FF   | OFF  | static | OFF   |
| ETB        | FF   | FF   | FF   | OFF  | static | OFF   |
| TPIU       | FF   | FF   | FF   | OFF  | static | OFF   |
| DWT        | FF   | FF   | FF   | OFF  | static | OFF   |

## 9.15 Debug & Security

When security is enabled (FSEC[SEC] != 10), the debug port capabilities are limited in order to prevent exploitation of secure data. In the secure state the debugger still has access to the MDM-AP Status Register and can determine the current security state of the device. In the case of a secure device, the debugger also has the capability of performing a mass erase operation via writes to the MDM-AP Control Register. In the case of a secure device that has mass erase disabled (FSEC[MEEN] = 10), attempts to mass erase via the debug interface are blocked.

# Chapter 10

## Signal Multiplexing and Signal Descriptions

### 10.1 Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The [Port Control](#) block controls which signal is present on the external pin. Reference that chapter to find which register controls the operation of a specific pin.

### 10.2 Signal Multiplexing Integration

This section summarizes how the module is integrated into the device. For a comprehensive description of the module itself, see the module's dedicated chapter.

**Figure 10-1. Signal multiplexing integration**

**Table 10-1. Reference links to related information**

| Topic             | Related module | Reference                         |
|-------------------|----------------|-----------------------------------|
| Full description  | Port control   | <a href="#">Port control</a>      |
| System memory map |                | <a href="#">System memory map</a> |

*Table continues on the next page...*

| Register access | Peripheral bus controller | <a href="#">Peripheral bridge</a>  |

### 10.2.1 Port control and interrupt module features

- Six 32-pin ports

**NOTE**

Not all pins are available on the device. See the following section for details.

- Each 32-pin port is assigned one interrupt.
- The digital filter option has two clock source options: bus clock and 1-kHz LPO. The 1-kHz LPO option gives users this feature in low power modes.
- The digital filter is configurable from 1 to 32 clock cycles when enabled.

### 10.2.2 PCRn reset values for port A

PCRn bit reset values for port A are 1 for the following bits:

- For PCR0: bits 1, 6, 8, 9, and 10.
- For PCR1 to PCR4: bits 0, 1, 6, 8, 9, and 10.
- For PCR5 : bits 0, 1, and 6.

All other PCRn bit reset values for port A are 0.

### 10.2.3 Clock gating

The clock to the port control module can be gated on and off using the SCGC5[PORTx] bits in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing the corresponding module, set SCGC5[PORTx] in the SIM module to enable the clock. Before turning off the clock, make sure to disable the module. For more details, refer to the clock distribution chapter.

## 10.2.4 Signal multiplexing constraints

1. A given peripheral function must be assigned to a maximum of one package pin. Do not program the same function to more than one pin.
2. To ensure the best signal timing for a given peripheral's interface, choose the pins in closest proximity to each other.

## 10.3 Pinout

### 10.3.1 K61 Signal Multiplexing and Pin Assignments

The following table shows the signals available on each pin and the locations of these pins on the devices supported by this document. The Port Control Module is responsible for selecting which ALT functionality is available on each pin.

| 144 MAP BGA | 143 WLC SP | Pin Name         | Default   | ALT0      | ALT1             | ALT2      | ALT3            | ALT4             | ALT5 | ALT6     | ALT7            | EzPort |
|-------------|------------|------------------|-----------|-----------|------------------|-----------|-----------------|------------------|------|----------|-----------------|--------|
| D3          | A11        | PTE0             | ADC1_SE4a | ADC1_SE4a | PTE0             | SPI1_PCS1 | UART1_TX        | SDHC0_D1         |      | I2C1_SDA | RTC_CLKOUT      |        |
| D2          | C10        | PTE1/<br>LLWU_P0 | ADC1_SE5a | ADC1_SE5a | PTE1/<br>LLWU_P0 | SPI1_SOUT | UART1_RX        | SDHC0_D0         |      | I2C1_SCL | SPI1_SIN        |        |
| D1          | B11        | PTE2/<br>LLWU_P1 | ADC1_SE6a | ADC1_SE6a | PTE2/<br>LLWU_P1 | SPI1_SCK  | UART1_CTS_<br>b | SDHC0_DCLK       |      |          |                 |        |
| E4          | D10        | PTE3             | ADC1_SE7a | ADC1_SE7a | PTE3             | SPI1_SIN  | UART1_RTS_<br>b | SDHC0_CMD        |      |          | SPI1_SOUT       |        |
| E5          | E7         | VDD              | VDD       | VDD       |                  |           |                 |                  |      |          |                 |        |
| F6          | E8         | VSS              | VSS       | VSS       |                  |           |                 |                  |      |          |                 |        |
| E3          | C11        | PTE4/<br>LLWU_P2 | DISABLED  |           | PTE4/<br>LLWU_P2 | SPI1_PCS0 | UART3_TX        | SDHC0_D3         |      |          |                 |        |
| E2          | D11        | PTE5             | DISABLED  |           | PTE5             | SPI1_PCS2 | UART3_RX        | SDHC0_D2         |      | FTM3_CH0 |                 |        |
| E1          | E9         | PTE6             | DISABLED  |           | PTE6             | SPI1_PCS3 | UART3_CTS_<br>b | I2S0_MCLK        |      | FTM3_CH1 | USB_SOF_<br>OUT |        |
| F4          | E10        | PTE7             | DISABLED  |           | PTE7             |           | UART3_RTS_<br>b | I2S0_RXD0        |      | FTM3_CH2 |                 |        |

### 10.3.2 K61 Pinouts

The below figure shows the pinout diagram for the devices supported by this document. Many signals may be multiplexed onto a single pin. To determine what signals can be used on which pin, see the previous section.

|   | 1  | 2  | 3  | 4  | 5                            | 6       | 7                  | 8                 | 9                 | 10               | 11               | 12      |   |

## 10.4 Module Signal Description Tables

The following sections correlate the chip-level signal name with the signal name used in the module's chapter. They also briefly describe the signal function and direction.

## 10.4.1 Core Modules

**Table 10-2. JTAG Signal Descriptions**

| Chip signal name | Module signal name     | Description              | I/O |
|------------------|------------------------|--------------------------|-----|
| JTAG_TMS         | JTAG_TMS/<br>SWD_DIO   | JTAG Test Mode Selection | I/O |
| JTAG_TCLK        | JTAG_TCLK/<br>SWD_CLK  | JTAG Test Clock          | I   |
| JTAG_TDI         | JTAG_TDI               | JTAG Test Data Input     | I   |
| JTAG_TDO         | JTAG_TDO/<br>TRACE_SWO | JTAG Test Data Output    | O   |
| JTAG_TRST        | JTAG_TRST_b            | JTAG Reset               | I   |

**Table 10-3. SWD Signal Descriptions**

| Chip signal name | Module signal name    | Description       | I/O |
|------------------|-----------------------|-------------------|-----|
| SWD_DIO          | JTAG_TMS/<br>SWD_DIO  | Serial Wire Data  | I/O |
| SWD_CLK          | JTAG_TCLK/<br>SWD_CLK | Serial Wire Clock | I   |

**Table 10-4. TPIU Signal Descriptions**

| Chip signal name | Module signal name     | Description   | I/O |
|------------------|------------------------|---|-----|
| TRACE_CLKOUT     | TRACECLK               | Trace clock output from the ARM CoreSight debug block   | O   |
| TRACE_D[3:2]     | TRACEDATA              | Trace output data from the ARM CoreSight debug block used for 5-pin interface                 | O   |
| TRACE_D[1:0]     | TRACEDATA              | Trace output data from the ARM CoreSight debug block used for both 5-pin and 3-pin interfaces | O   |
| TRACE_SWO        | JTAG_TDO/<br>TRACE_SWO | Trace output data from the ARM CoreSight debug block over a single pin                        | O   |

## 10.4.2 System Modules

**Table 10-5. System Signal Descriptions**

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| NMI              | —                  | Non-maskable interrupt<br><br><b>NOTE:</b> Driving the $\overline{\text{NMI}}$ signal low forces a non-maskable interrupt, if the $\overline{\text{NMI}}$ function is selected on the corresponding pin. | I   |
| RESET            | —                  | Reset input signal   | I   |
| VDD              | —                  | MCU power  | I   |
| VDDINT           | —                  | Core power supply  | I   |
| VSS              | —                  | MCU ground   | I   |

**Table 10-6. EWM Signal Descriptions**

| Chip signal name | Module signal name           | Description  | I/O |
|------------------|------------------------------|--|-----|
| EWM_IN           | EWM_in                       | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low. | I   |
| EWM_OUT          | $\overline{\text{EWM\_out}}$ | EWM reset out signal   | O   |

## 10.4.3 Clock Modules

**Table 10-7. OSC Signal Descriptions**

| Chip signal name | Module signal name | Description                     | I/O |
|------------------|--------------------|---------------------------------|-----|
| EXTAL0           | EXTAL              | External clock/Oscillator input | I   |
| XTAL0            | XTAL               | Oscillator output               | O   |

**Table 10-8. RTC OSC Signal Descriptions**

| Chip signal name | Module signal name | Description                  | I/O |
|------------------|--------------------|------------------------------|-----|
| EXTAL32          | EXTAL32            | 32.768 kHz oscillator input  | I   |
| XTAL32           | XTAL32             | 32.768 kHz oscillator output | O   |

## 10.4.4 Memories and Memory Interfaces

**Table 10-9. EzPort Signal Descriptions**

| Chip signal name | Module signal name | Description            | I/O    |
|------------------|--------------------|------------------------|--------|
| EZP_CLK          | EZP_CK             | EzPort Clock           | Input  |
| EZP_CS           | EZP_CS             | EzPort Chip Select     | Input  |
| EZP_DI           | EZP_D              | EzPort Serial Data In  | Input  |
| EZP_DO           | EZP_Q              | EzPort Serial Data Out | Output |

**Table 10-10. FlexBus Signal Descriptions**

| Chip signal name  | Module signal name                                    | Description   | I/O |
|---|---|---|-----|
| FB_CLKOUT   | FB_CLK  | FlexBus Clock Output  | O   |
| FB_A[29:16]   | FB_A[29:16]   | Address Bus<br>When FlexBus is used in a nonmultiplexed configuration, this is the address bus. When FlexBus is used in a multiplexed configuration, this bus is not used.  | O   |
| FB_AD[31:0]   | FB_D31–FB_D0  | Data Bus—During the first cycle, this bus drives the upper address byte, addr[31:24].<br>When FlexBus is used in a nonmultiplexed configuration, this is the data bus, FB_D. When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD.<br>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.<br>When FlexBus is used in a multiplexed configuration, the full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0. | I/O |
| FB_CS[5:0]  | FB_CS5–FB_CS0   | General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].  | O   |
| FB_BE31_24_BLS7_0,<br>FB_BE23_16_BLS15_8,<br>FB_BE15_8_BLS23_16,<br>FB_BE7_0_BLS31_24 | FB_BE_31_24<br>FB_BE_23_16<br>FB_BE_15_8<br>FB_BE_7_0 | Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.<br>For external SRAM or flash devices, the FB_BE outputs should be connected to individual byte strobe signals.   | O   |
| FB_OE   | FB_OE   | Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.   | O   |

Table continues on the next page...

**Table 10-10. FlexBus Signal Descriptions  
(continued)**

| Chip signal name       | Module signal name | Description  | I/O |
|------------------------|--------------------|--|-----|
| FB_R $\bar{W}$         | FB_R/ $\bar{W}$    | Read/Write—Indicates whether the current bus operation is a read operation (FB_R/ $\bar{W}$ high) or a write operation (FB_R/ $\bar{W}$ low).  | O   |
| FB $\bar{TS}$ / FB_ALE | FB $\bar{TS}$      | <p>Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid.</p> <p>An inverted FB<math>\bar{TS}</math> is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.</p> <p>FB<math>\bar{TS}</math>/FB_ALE is asserted for one bus clock cycle.</p> <p>The chip can extend this signal until the first positive clock edge after FB<math>\bar{CS}</math> asserts. See CSCR[EXTS] and <a href="#">Extended Transfer Start/Address Latch Enable</a>.</p>   | O   |
| FB_TSIZ[1:0]           | FB_TSIZ1–FB_TSIZ0  | <p>Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports.</p> <ul style="list-style-type: none"> <li>• 00b = 4 bytes</li> <li>• 01b = 1 byte</li> <li>• 10b = 2 bytes</li> <li>• 11b = 16 bytes (line)</li> </ul> <p>For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b).</p> <p>For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows:</p> <ul style="list-style-type: none"> <li>• If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size.</li> <li>• If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size.</li> </ul> <p>For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each FB<math>\bar{TS}</math> assertion to reflect the next transfer size.</p> <p>For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.</p> | O   |

Table continues on the next page...

**Table 10-10. FlexBus Signal Descriptions  
(continued)**

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| FB_TA            | FB_TA              | <p>Transfer Acknowledge—Indicates that the external data transfer is complete. When <math>\overline{\text{FB\_TA}}</math> is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When <math>\overline{\text{FB\_TA}}</math> is asserted during a write transfer, the transfer is terminated.</p> <p>If auto-acknowledge is disabled (<math>\text{CSCR}[\text{AA}] = 0</math>), the external memory or peripheral drives <math>\overline{\text{FB\_TA}}</math> to terminate the transfer. If auto-acknowledge is enabled (<math>\text{CSCR}[\text{AA}] = 1</math>), <math>\overline{\text{FB\_TA}}</math> is generated internally after a specified number of wait states, or the external memory or peripheral may assert external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown to terminate the transfer early. The chip deasserts <math>\overline{\text{FB\_CS}}</math> one cycle after the last <math>\overline{\text{FB\_TA}}</math> is asserted. During read transfers, the external memory or peripheral must continue to drive data until <math>\overline{\text{FB\_TA}}</math> is recognized. For write transfers, the chip continues driving data one clock cycle after <math>\overline{\text{FB\_CS}}</math> is deasserted.</p> <p>The number of wait states is determined by CSCR or the external <math>\overline{\text{FB\_TA}}</math> input. If the external <math>\overline{\text{FB\_TA}}</math> is used, the external memory or peripheral has complete control of the number of wait states.</p> <p><b>Note:</b> External memory or peripherals should assert <math>\overline{\text{FB\_TA}}</math> only while the <math>\overline{\text{FB\_CS}}</math> signal to the external memory or peripheral is asserted.</p> <p>The CSPMCR register controls muxing of <math>\overline{\text{FB\_TA}}</math> with other signals. If auto-acknowledge is not used and CSPMCR does not allow <math>\overline{\text{FB\_TA}}</math> control, FlexBus may hang.</p> | I   |
| FB_TBST          | FB_TBST            | <p>Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on <math>\text{FB\_TSIZ1}</math>–<math>\text{FB\_TSIZ0}</math> and the port size.</p> <p><b>Note:</b> When a burst transfer is in progress (<math>\text{FB\_TBST} = 0\text{b}</math>), the transfer size is 16 bytes (<math>\text{FB\_TSIZ1}</math>–<math>\text{FB\_TSIZ0} = 11\text{b}</math>), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.</p>   | O   |

## 10.4.5 Security Modules

**Table 10-11. Tamper Detect Signal Descriptions**

| Chip signal name | Module signal name | Description                                   | I/O |
|------------------|--------------------|---|-----|
| TAMPER[5:0]      | TAMPER[7:0]        | External tamper input or active tamper output | I/O |

## 10.4.6 Analog

**Table 10-12. ADC 0 Signal Descriptions**

| Chip signal name                      | Module signal name | Description                        | I/O |
|---------------------------------------|--------------------|------------------------------------|-----|
| ADC0_DP3,<br>PGA0_DP,<br>ADC0_DP[1:0] | DADP3–DADP0        | Differential Analog Channel Inputs | I   |
| ADC0_DM3,<br>PGA0_DM,<br>ADC0_DM[1:0] | DADM3–DADM0        | Differential Analog Channel Inputs | I   |
| ADC0_SE[18:4]                         | AD $n$             | Single-Ended Analog Channel Inputs | I   |
| VREFH                                 | V <sub>REFSH</sub> | Voltage Reference Select High      | I   |
| VREFL                                 | V <sub>REFSL</sub> | Voltage Reference Select Low       | I   |
| VDDA                                  | V <sub>DDA</sub>   | Analog Power Supply                | I   |
| VSSA                                  | V <sub>SSA</sub>   | Analog Ground                      | I   |

**Table 10-13. CMP 0 Signal Descriptions**

| Chip signal name | Module signal name | Description           | I/O |
|------------------|--------------------|-----------------------|-----|
| CMP0_IN[5:0]     | IN[5:0]            | Analog voltage inputs | I   |
| CMP0_OUT         | CMPO               | Comparator output     | O   |

**Table 10-14. DAC 0 Signal Descriptions**

| Chip signal name | Module signal name | Description | I/O |
|------------------|--------------------|-------------|-----|

| CMT_IRO          | CMT_IRO            | Infrared Output | O   |

**Table 10-22. PDB 0 Signal Descriptions**

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| PDB0_EXTRG       | EXTRG              | External Trigger Input Source<br>If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter. | I   |

**Table 10-23. LPTMR 0 Signal Descriptions**

| Chip signal name | Module signal name | Description             | I/O |
|------------------|--------------------|-------------------------|-----|
| LPTMR0_ALT[2:1]  | LPTMR_ALT $n$      | Pulse Counter Input pin | I   |

**Table 10-24. RTC Signal Descriptions**

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| VBAT             | —                  | Backup battery supply for RTC and VBAT register file | I   |
| RTC_CLKOUT       | RTC_CLKOUT         | 1 Hz square-wave output or OSCERCLK                  | O   |
| RTC_WAKEUP       | RTC_WAKEUP         | Wakeup for external device                           | I/O |

## Module Signal Description Tables

| Chip signal name    | Module signal name | Description   | I/O |
|---------------------|--------------------|---|-----|
| ENET0_1588_TMR[3:0] | 1588_TMR $n$       | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<math>n</math> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<math>n</math> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<math>n</math>.</p> <p>An interrupt can be triggered if ENET_TCSR<math>n</math>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<math>n</math>[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN     | 1588_TMR $n$       | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<math>n</math> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<math>n</math> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<math>n</math>.</p> <p>An interrupt can be triggered if ENET_TCSR<math>n</math>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<math>n</math>[TDRE] is set.</p> | I/O |

## 10.4.8 Communication Interfaces

### Ethernet MII Signal Descriptions

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| MII0_COL         | MII_COL            | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.   | I   |
| MII0_CRD         | MII_CRD            | Carrier sense. When asserted, indicates transmit or receive medium is not idle.<br><br>In RMI mode, this signal is present on the RMII_CRD_DV pin.   | I   |
| MII0_MDC         | MII_MDC            | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.   | O   |
| MII0_MDIO        | MII_MDIO           | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.   | I/O |
| MII0_RXCLK       | MII_RXCLK          | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.   | I   |
| MII0_RXDV        | MII_RXDV           | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMI mode, this pin also generates the CRD signal. | I   |
| MII0_RXD[3:0]    | MII_RXD[3:0]       | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.  | I   |
| MII0_RXER        | MII_RXER           | When asserted with RXDV, indicates the PHY detects an error in the current frame.  | I   |
| MII0_TXCLK       | MII_TXCLK          | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.   | I   |
| MII0_TXD[3:0]    | MII_TXD[3:0]       | Serial output Ethernet data. Only valid during TXEN assertion.   | O   |

*Table continues on the next page...*

## Module Signal Description Tables

| Chip signal name | Module signal name | Description  | I/O |
|------------------|--------------------|--|-----|
| MII0_TXEN        | MII_TXEN           | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame. | O   |
| MII0_TXER        | MII_TXER           | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.   | O   |

## Ethernet RMII Signal Descriptions

| Chip signal name | Module signal name | Description   | I/O |
|------------------|--------------------|---|-----|
| RMII0_MDC        | RMII_MDC           | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.  | O   |
| RMII0_MDIO       | RMII_MDIO          | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.  | I/O |
| RMII0_CRSDV      | RMII_CRSDV         | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| RMII0_RXD[1:0]   | RMII_RXD[1:0]      | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.   | I   |
| RMII0_RXER       | RMII_RXER          | When asserted with RXDV, indicates the PHY detects an error in the current frame.   | I   |
| RMII0_TXD[1:0]   | RMII_TXD[1:0]      | Serial output Ethernet data. Only valid during TXEN assertion.  | O   |

*Table continues on the next page...*

| Chip signal name                     | Module signal name | Description  | I/O |
|--------------------------------------|--------------------|--|-----|
| RMII0_TXEN                           | RMII_TXEN          | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame. | O   |
| Internal OSCERCLK clock <sup>1</sup> | RMII_REF_CLK       | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.   | I   |

**Table 10-25. USB HS OTG Signal Descriptions**

| Chip signal name | Module signal name | Description                                  | I/O |
|------------------|--------------------|--|-----|
| ULPI_DATA[7:0]   | ULPI_DATA[7:0]     | Data bit <i>n</i>                            | I/O |
| ULPI_CLK         | ULPI_CLK           | 60 MHz clock input from the ULPI transceiver | I   |
| ULPI_DIR         | ULPI_DIR           | Controls data bus direction                  | I   |
| ULPI_NXT         | ULPI_NXT           | Next data                                    | I   |
| ULPI_STP         | ULPI_STP           | Indicates the end of a transfer on the bus   | O   |

**Table 10-26. USB FS OTG Signal Descriptions**

| Chip signal name | Module signal name | Description   | I/O |
|------------------|--------------------|---|-----|
| USB0_DM          | usb_dm             | USB D- analog data signal on the USB bus.   | I/O |
| USB0_DP          | usb_dp             | USB D+ analog data signal on the USB bus.   | I/O |
| USB_CLKIN        | —                  | Alternate USB clock input   | I   |
| USB_SOF_OUT      | —                  | USB start of frame signal. Can be used to make the USB start of frame available for external synchronization. | O   |

**Table 10-27. USB VREG Signal Descriptions**

| Chip signal name | Module signal name | Description              | I/O |
|------------------|--------------------|--------------------------|-----|
| VOUT33           | reg33_out          | Regulator output voltage | O   |
| VREGIN           | reg33_in           | Unregulated power supply | I   |

| PTB[31:0] <sup>1</sup> | PORTB31–PORTB0     | General-purpose input/output | I/O |
| PTC[31:0] <sup>1</sup> | PORTC31–PORTC0     | General-purpose input/output | I/O |
| PTD[31:0] <sup>1</sup> | PORTD31–PORTD0     | General-purpose input/output | I/O |
| PTE[31:0] <sup>1</sup> | PORTE31–PORTE0     | General-purpose input/output | I/O |
| PTF[31:0] <sup>1</sup> | PORTF31–PORTF0     | General-purpose input/output | I/O |

1. The available GPIO pins depends on the specific package. See the signal multiplexing section for which exact GPIO signals are available.

# Chapter 11

## Port Control and Interrupts (PORT)

### 11.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

### 11.2 Overview

The Port Control and Interrupt (PORT) module provides support for port control, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

#### 11.2.1 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin
  - Asynchronous wake-up in low-power modes
  - Pin interrupt is functional in all digital pin muxing modes
- Port control

- Individual pull control fields with pullup, pulldown, and pull-disable support on selected pins
- Individual drive strength field supporting high and low drive strength on selected pins
- Individual slew rate field supporting fast and slow slew rates on selected pins
- Individual input passive filter field supporting enable and disable of the individual input passive filter on selected pins
- Individual open drain field supporting enable and disable of the individual open drain output on selected pins
- Individual mux control field supporting analog or pin disabled, GPIO, and up to six chip-specific digital functions
- Pad configuration fields are functional in all digital pin muxing modes.

## 11.2.2 Modes of operation

### 11.2.2.1 Run mode

In Run mode, the PORT operates normally.

### 11.2.2.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

### 11.2.2.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

### 11.2.2.4 Debug mode

In Debug mode, PORT operates normally.

## 11.3 External signal description

The table found here describes the PORT external signal.

**Table 11-1. Signal properties**

| Name        | Function           | I/O | Reset | Pull |
|-------------|--------------------|-----|-------|------|
| PORTx[31:0] | External interrupt | I/O | 0     | -    |

### NOTE

Not all pins within each port are implemented on each device.

## 11.4 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

**Table 11-2. PORT interface—detailed signal description**

| Signal      | I/O | Description         |   |
|-------------|-----|---------------------|---|
| PORTx[31:0] | I/O | External interrupt. |   |
|             |     | State meaning       | Asserted—pin is logic 1.<br>Negated—pin is logic 0.   |
|             |     | Timing              | Assertion—may occur at any time and can assert asynchronously to the system clock.<br>Negation—may occur at any time and can assert asynchronously to the system clock. |

## 11.5 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

### PORT memory map

| Absolute address (hex) | Register name                       | Width (in bits) | Access | Reset value                 | Section/page               |
|------------------------|-------------------------------------|-----------------|--------|-----------------------------|----------------------------|
| 4004_9000              | Pin Control Register n (PORTA_PCR0) | 32              | R/W    | <a href="#">See section</a> | <a href="#">11.5.1/298</a> |
| 4004_9004              | Pin Control Register n (PORTA_PCR1) | 32              | R/W    | <a href="#">See section</a> | <a href="#">11.5.1/298</a> |

## 11.5.1 Pin Control Register n (PORTx\_PCRn)

### NOTE

See the Signal Multiplexing and Pin Assignment chapter for the reset value of this device.

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 0h offset + (4d × i), where i=0d to 31d

\* Notes:

- MUX field: Varies by port. See Signal Multiplexing and Signal Descriptions chapter for reset values per port.
- DSE field: Varies by port. See the Signal Multiplexing and Signal Descriptions chapter for reset values per port.
- PFE field: Varies by port. See Signal Multiplexing and Signal Descriptions chapter for reset values per port.
- SRE field: Varies by port. See Signal Multiplexing and Signal Descriptions chapter for reset values per port.
- PE field: Varies by port. See Signal Multiplexing and Signal Descriptions chapter for reset values per port.
- PS field: Varies by port. See Signal Multiplexing and Signal Descriptions chapter for reset values per port.

### PORTx\_PCRn field descriptions

| Field             | Description  |
|-------------------|--|
| 31–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.            |
| 24<br>ISF         | Interrupt Status Flag<br>The pin interrupt configuration is valid in all digital pin muxing modes. |

*Table continues on the next page...*

**PORTx\_PCRn field descriptions (continued)**

| Field             | Description  |
|-------------------|--|
|                   | 0 Configured interrupt is not detected.<br>1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.   |
| 23–20<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 19–16<br>IRQC     | Interrupt Configuration<br><br>The pin interrupt configuration is valid in all digital pin muxing modes. The corresponding pin is configured to generate interrupt/DMA request as follows:<br><br>0000 Flag is disabled.<br>0001 Flag and DMA request on rising edge.<br>0010 Flag and DMA request on falling edge.<br>0011 Flag and DMA request on either edge.<br>0100 Reserved.<br>0101 Reserved.<br>0110 Reserved.<br>0111 Reserved.<br>1000 Flag and Interrupt when logic 0.<br>1001 Flag and Interrupt on rising-edge.<br>1010 Flag and Interrupt on falling-edge.<br>1011 Flag and Interrupt on either edge.<br>1100 Flag and Interrupt when logic 1.<br>1101 Reserved.<br>1110 Reserved.<br>1111 Reserved. |
| 15<br>LK          | Lock Register<br><br>0 Pin Control Register fields [15:0] are not locked.<br>1 Pin Control Register fields [15:0] are locked and cannot be updated until the next system reset.  |
| 14–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 10–8<br>MUX       | Pin Mux Control<br><br>Not all pins support all pin muxing slots. Unimplemented pin muxing slots are reserved and may result in configuring the pin for a different pin muxing slot.<br><br>The corresponding pin is configured in the following pin muxing slot as follows:<br><br>000 Pin disabled (analog).<br>001 Alternative 1 (GPIO).<br>010 Alternative 2 (chip-specific).<br>011 Alternative 3 (chip-specific).<br>100 Alternative 4 (chip-specific).<br>101 Alternative 5 (chip-specific).<br>110 Alternative 6 (chip-specific).<br>111 Alternative 7 (chip-specific).  |

*Table continues on the next page...*

**PORTx\_PCRn field descriptions (continued)**

| Field         | Description  |
|---------------|--|
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 6<br>DSE      | Drive Strength Enable<br><br>This field is read-only for pins that do not support a configurable drive strength.<br>Drive strength configuration is valid in all digital pin muxing modes.<br><br>0 Low drive strength is configured on the corresponding pin, if pin is configured as a digital output.<br>1 High drive strength is configured on the corresponding pin, if pin is configured as a digital output.  |
| 5<br>ODE      | Open Drain Enable<br><br>This field is read-only for pins that do not support a configurable open drain output.<br>Open drain configuration is valid in all digital pin muxing modes.<br><br>0 Open drain output is disabled on the corresponding pin.<br>1 Open drain output is enabled on the corresponding pin, if the pin is configured as a digital output.   |
| 4<br>PFE      | Passive Filter Enable<br><br>This field is read-only for pins that do not support a configurable passive input filter.<br>Passive filter configuration is valid in all digital pin muxing modes.<br><br>0 Passive input filter is disabled on the corresponding pin.<br>1 Passive input filter is enabled on the corresponding pin, if the pin is configured as a digital input. Refer to the device data sheet for filter characteristics.  |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 2<br>SRE      | Slew Rate Enable<br><br>This field is read-only for pins that do not support a configurable slew rate.<br>Slew rate configuration is valid in all digital pin muxing modes.<br><br>0 Fast slew rate is configured on the corresponding pin, if the pin is configured as a digital output.<br>1 Slow slew rate is configured on the corresponding pin, if the pin is configured as a digital output.  |
| 1<br>PE       | Pull Enable<br><br>This field is read-only for pins that do not support a configurable pull resistor. Refer to the Chapter of Signal Multiplexing and Signal Descriptions for the pins that support a configurable pull resistor.<br>Pull configuration is valid in all digital pin muxing modes.<br><br>0 Internal pullup or pulldown resistor is not enabled on the corresponding pin.<br>1 Internal pullup or pulldown resistor is enabled on the corresponding pin, if the pin is configured as a digital input. |
| 0<br>PS       | Pull Select<br><br>This bit is read only for pins that do not support a configurable pull resistor direction.<br>Pull configuration is valid in all digital pin muxing modes.<br><br>0 Internal pulldown resistor is enabled on the corresponding pin, if the corresponding PE field is set.<br>1 Internal pullup resistor is enabled on the corresponding pin, if the corresponding PE field is set.  |

## 11.5.2 Global Pin Control Low Register (PORTx\_GPCLR)

Only 32-bit writes are supported to this register.

Address: Base address + 80h offset

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

## 11.5.4 Interrupt Status Flag Register (PORTx\_ISFR)

The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Pin Control Register, and each flag can be cleared in either location.

Address: Base address + A0h offset

**PORTx\_ISFR field descriptions**

| Field       | Description  |
|-------------|--|
| 31–0<br>ISF | <p>Interrupt Status Flag</p> <p>Each bit in the field indicates the detection of the configured interrupt of the same number as the field.</p> <p>0 Configured interrupt is not detected.</p> <p>1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.</p> |

## 11.6 Functional description

### 11.6.1 Pin control

Each port pin has a corresponding Pin Control register, PORT\_PCRn, associated with it.

The upper half of the Pin Control register configures the pin's capability to either interrupt the CPU or request a DMA transfer, on a rising/falling edge or both edges as well as a logic level occurring on the port pin. It also includes a flag to indicate that an interrupt has occurred.

The lower half of the Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup or pulldown enable on selected pins
- Drive strength and slew rate configuration on selected pins

- Open drain enable on selected pins
- Passive input filter enable on selected pins
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an I<sup>2</sup>C function is enabled on a pin, that does not override the pullup or open drain configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

A lock field also exists that allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that pin control register are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO\_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

## 11.6.2 Global pin control

The two global pin control registers allow a single register write to update the lower half of the pin control register on up to 16 pins, all with the same value. Registers that are locked cannot be written using the global pin control registers.

The global pin control registers are designed to enable software to quickly configure multiple pins within the one port for the same peripheral function. However, the interrupt functions cannot be configured using the global pin control registers.

The global pin control registers are write-only registers, that always read as 0.

### 11.6.3 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin . When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT\_ISFR or PORT\_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

# Chapter 12

## System integration module (SIM)

### 12.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The system integration module (SIM) provides system control and chip configuration registers.

#### 12.1.1 Features

- Configuration for system clocking
  - Clock source selection for ESDHC, I<sup>2</sup>S, Ethernet timestamp, NFC, USB, and PLL/FLL source
  - System clock divide values
  - NFC, I<sup>2</sup>S, and USB clock divide values
- Architectural clock gating control
- Flash configuration
- USB regulator configuration
- RAM repair control
- Flextimer external clock and fault source selection
- UART0 and UART1 receive/transmit source selection/configuration

#### 12.1.2 Modes of operation

- Run mode
- Sleep mode
- Deep sleep mode
- VLLS mode

## 12.2 Memory Map and Registers

### NOTE

The SIM\_SOPT1 and SIM\_SOPT1CFG register sare located at a different base address than the other SIM registers.

### SIM memory map

| Absolute address (hex) | Register name                                       | Width (in bits) | Access | Reset value                 | Section/ page               |

\* Notes:

- x = Undefined at reset.

### SIM\_SOPT5 field descriptions

| Field             | Description  |
|-------------------|--|
| 31–8<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7–6<br>UART1RXSRC | UART1 receive data source select<br>Selects the source for the UART1 receive data.<br><br>00 UART1_RX pin<br>01 CMP0<br>10 CMP1<br>11 Reserved   |
| 5–4<br>UART1TXSRC | UART1 transmit data source select<br>Selects the source for the UART1 transmit data.<br><br>00 UART1_TX pin<br>01 UART1_TX pin modulated with FTM1 channel 0 Output<br>10 UART1_TX pin modulated with FTM2 channel 0 Output<br>11 Reserved |
| 3–2<br>UART0RXSRC | UART0 receive data source select<br>Selects the source for the UART0 receive data.<br><br>00 UART0_RX pin<br>01 CMP0   |

Table continues on the next page...

### SIM\_SOPT5 field descriptions (continued)

| Field             | Description  |
|-------------------|--|
|                   | 10 CMP1<br>11 Reserved   |
| 1–0<br>UART0TXSRC | UART0 transmit data source select<br><br>Selects the source for the UART0 transmit data.<br><br>00 UART0_TX pin<br>01 UART0_TX pin modulated with FTM1 channel 0 output<br>10 UART0_TX pin modulated with FTM2 channel 0 output<br>11 Reserved |

### 12.2.6 System Options Register 6 (SIM\_SOPT6)

Address: 4004\_7000h base + 1014h offset = 4004\_8014h

### SIM\_SOPT6 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–20<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 19–16<br>PCR      | PCR<br><br>FlexBus hold cycles before FlexBus can release bus to NFC or to IDLE.        |
| 15–0<br>MCC       | MCC<br><br>NFC hold cycle in case FlexBus request while NFC is granted.                 |

## 12.2.7 System Options Register 7 (SIM\_SOPT7)

Address: 4004\_7000h base + 1018h offset = 4004\_8018h

### SIM\_SOPT7 field descriptions

| Field               | Description   |
|---------------------|---|
| 31<br>ADC3ALTTTRGEN | ADC3 alternate trigger enable<br>Enable alternative conversion triggers for ADC3.<br><br>0 PDB trigger selected for ADC3.<br>1 Alternate trigger selected for ADC3.   |
| 30–29<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 28<br>ADC3PRETRGSEL | ADC3 pre-trigger select<br>Selects the ADC3 pre-trigger source when alternative triggers are enabled through ADC3ALTTTRGEN.<br><br>0 Pre-trigger A selected for ADC3.<br>1 Pre-trigger B selected for ADC3.   |
| 27–24<br>ADC3TRGSEL | ADC3 trigger select<br>Selects the ADC3 trigger source when alternative triggers are enabled through ADC3ALTTTRGEN.<br><br>0000 External trigger<br>0001 High speed comparator 0 asynchronous interrupt<br>0010 High speed comparator 1 asynchronous interrupt<br>0011 High speed comparator 2 asynchronous interrupt<br>0100 PIT trigger 0<br>0101 PIT trigger 1<br>0110 PIT trigger 2<br>0111 PIT trigger 3 |

Table continues on the next page...

**SIM\_SOPT7 field descriptions (continued)**

| Field               | Description  |
|---------------------|--|
|                     | 1000 FTM0 trigger<br>1001 FTM1 trigger<br>1010 FTM2 trigger<br>1011 FTM3 trigger<br>1100 RTC alarm<br>1101 RTC seconds<br>1110 Low-power timer trigger<br>1111 High speed comparator 3 asynchronous interrupt  |
| 23<br>ADC2ALTTTRGEN | ADC2 alternate trigger enable<br>Enable alternative conversion triggers for ADC2.<br>0 PDB trigger selected for ADC2.<br>1 Alternate trigger selected for ADC2.  |
| 22–21<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 20<br>ADC2PRETRGSEL | ADC2 pre-trigger select<br>Selects the ADC2 pre-trigger source when alternative triggers are enabled through ADC2ALTTTRGEN.<br>0 Pre-trigger A selected for ADC2.<br>1 Pre-trigger B selected for ADC2.  |
| 19–16<br>ADC2TRGSEL | ADC2 trigger select<br>Selects the ADC2 trigger source when alternative triggers are enabled through ADC2ALTTTRGEN.<br>0000 External trigger<br>0001 High speed comparator 0 asynchronous interrupt<br>0010 High speed comparator 1 asynchronous interrupt<br>0011 High speed comparator 2 asynchronous interrupt<br>0100 PIT trigger 0<br>0101 PIT trigger 1<br>0110 PIT trigger 2<br>0111 PIT trigger 3<br>1000 FTM0 trigger<br>1001 FTM1 trigger<br>1010 FTM2 trigger<br>1011 FTM3 trigger<br>1100 RTC alarm<br>1101 RTC seconds<br>1110 Low-power timer trigger<br>1111 High speed comparator 3 asynchronous interrupt |
| 15<br>ADC1ALTTTRGEN | ADC1 alternate trigger enable<br>Enable alternative conversion triggers for ADC1.<br>0 PDB trigger selected for ADC1.<br>1 Alternate trigger selected for ADC1.  |

*Table continues on the next page...*

**SIM\_SOPT7 field descriptions (continued)**

| Field               | Description  |
|---------------------|--|
| 14–13<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 12<br>ADC1PRETRGSEL | ADC1 pre-trigger select<br>Selects the ADC1 pre-trigger source when alternative triggers are enabled through ADC1ALTTTRGEN.<br><br>0 Pre-trigger A selected for ADC1.<br>1 Pre-trigger B selected for ADC1.  |
| 11–8<br>ADC1TRGSEL  | ADC1 trigger select<br>Selects the ADC1 trigger source when alternative triggers are enabled through ADC1ALTTTRGEN.<br><br>0000 External trigger<br>0001 High speed comparator 0 asynchronous interrupt<br>0010 High speed comparator 1 asynchronous interrupt<br>0011 High speed comparator 2 asynchronous interrupt<br>0100 PIT trigger 0<br>0101 PIT trigger 1<br>0110 PIT trigger 2<br>0111 PIT trigger 3<br>1000 FTM0 trigger<br>1001 FTM1 trigger<br>1010 FTM2 trigger<br>1011 FTM3 trigger<br>1100 RTC alarm<br>1101 RTC seconds<br>1110 Low-power timer trigger<br>1111 High speed comparator 3 asynchronous interrupt |
| 7<br>ADC0ALTTTRGEN  | ADC0 alternate trigger enable<br>Enable alternative conversion triggers for ADC0.<br><br>0 PDB trigger selected for ADC0.<br>1 Alternate trigger selected for ADC0.  |
| 6–5<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4<br>ADC0PRETRGSEL  | ADC0 pre-trigger select<br>Selects the ADC0 pre-trigger source when alternative triggers are enabled through ADC0ALTTTRGEN.<br><br>0 Pre-trigger A selected for ADC0.<br>1 Pre-trigger B selected for ADC0.  |
| 3–0<br>ADC0TRGSEL   | ADC0 trigger select<br>Selects the ADC0 trigger source when alternative triggers are enabled through ADC0ALTTTRGEN.<br><br>0000 External trigger<br>0001 High speed comparator 0 asynchronous interrupt<br>0010 High speed comparator 1 asynchronous interrupt<br>0011 High speed comparator 2 asynchronous interrupt  |

*Table continues on the next page...*

### SIM\_SOPT7 field descriptions (continued)

| Field | Description                                    |
|-------|--|
| 0100  | PIT trigger 0                                  |
| 0101  | PIT trigger 1                                  |
| 0110  | PIT trigger 2                                  |
| 0111  | PIT trigger 3                                  |
| 1000  | FTM0 trigger                                   |
| 1001  | FTM1 trigger                                   |
| 1010  | FTM2 trigger                                   |
| 1011  | FTM3 trigger                                   |
| 1100  | RTC alarm                                      |
| 1101  | RTC seconds                                    |
| 1110  | Low-power timer trigger                        |
| 1111  | High speed comparator 3 asynchronous interrupt |

### 12.2.8 System Device Identification Register (SIM\_SDID)

Address: 4004\_7000h base + 1024h offset = 4004\_8024h

|       |          |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
|-------|----------|----|----|----|----|----|----|----|-------|----|----|----|-------|----|----|----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23    | 22 | 21 | 20 | 19    | 18 | 17 | 16 |
| R     | 0        |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0     | 0  | 0  | 0  |

| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1     | x* | x* | x* | x*    | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### SIM\_SDID field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–12<br>REVID    | Device revision number<br>Specifies the silicon implementation number for the device.   |
| 11–10<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 9<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 8<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 1. |

Table continues on the next page...

### SIM\_SDID field descriptions (continued)

| Field         | Description   |
|---------------|---|
| 7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 1.   |
| 6–4<br>FAMID  | Kinetis family identification<br><br>Specifies the Kinetis family of the device.<br><br>000 K10<br>001 K20<br>010 K61<br>011 Reserved<br>100 K60<br>101 K70<br>110 Reserved<br>111 Reserved   |
| 3–0<br>PINID  | Pincount identification<br><br>Specifies the pincount of the device.<br><br>0000 Reserved<br>0001 Reserved<br>0010 Reserved<br>0011 Reserved<br>0100 Reserved<br>0101 Reserved<br>0110 Reserved<br>0111 Reserved<br>1000 Reserved<br>1001 Reserved<br>1010 144-pin<br>1011 Reserved<br>1100 196-pin<br>1101 Reserved<br>1110 256-pin<br>1111 Reserved |

## 12.2.9 System Clock Gating Control Register 1 (SIM\_SCGC1)

Address: 4004\_7000h base + 1028h offset = 4004\_8028h

**SIM\_SCGC1 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–12<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 11<br>UART5       | UART5 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 10<br>UART4       | UART4 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 9–6<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 5<br>OSC1         | OSC1 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                  |
| 4–0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

## 12.2.10 System Clock Gating Control Register 2 (SIM\_SCGC2)

Address: 4004\_7000h base + 102Ch offset = 4004\_802Ch

**SIM\_SCGC2 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 13<br>DAC1        | 12BDAC1 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.               |
| 12<br>DAC0        | 12BDAC0 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.               |
| 11–1<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 0<br>ENET         | ENET clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                  |

## 12.2.11 System Clock Gating Control Register 3 (SIM\_SCGC3)

Address: 4004\_7000h base + 1030h offset = 4004\_8030h

|       |      |    |    |       |      |    |      |      |    |    |    |          |    |       |      |    |
|-------|------|----|----|-------|------|----|------|------|----|----|----|----------|----|-------|------|----|

| R     | 0  |    | UART3 | UART2 | UART1 | UART0 | 0  |    | IIC1 | IIC0 | 1    | 1   | 0     | CMT | EWM | 0  |
| W     | █  |    | █     | █     | █     | █     | █  |    | █    | █    | █    | █   | █     | █   | █   | █  |
| Reset | 0  | 0  | 0     | 0     | 0     | 0     | 0  | 0  | 0    | 0    | 1    | 1   | 0     | 0   | 0   | 0  |

### SIM\_SCGC4 field descriptions

| Field             | Description  |
|-------------------|--|
| 31<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 1.  |
| 30<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 1.  |
| 29<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 1.  |
| 28<br>LLWU        | LLWU Clock Gate Control<br><br>This bit controls the clock gate to the LLWU module.<br><br>0 Clock is disabled.<br>1 Clock is enabled. |
| 27–21<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 20<br>VREF        | VREF clock gate control<br><br>0 Clock is disabled.<br>1 Clock is enabled.   |
| 19<br>CMP         | Comparator clock gate control<br><br>0 Clock is disabled.<br>1 Clock is enabled.   |
| 18<br>USBFS       | USB FS clock gate control<br><br>0 Clock is disabled.<br>1 Clock is enabled.   |
| 17–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

Table continues on the next page...

### SIM\_SCGC4 field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 13<br>UART3     | UART3 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 12<br>UART2     | UART2 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 11<br>UART1     | UART1 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 10<br>UART0     | UART0 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 9–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 7<br>IIC1       | IIC1 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                  |
| 6<br>IIC0       | IIC0 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                  |
| 5<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 4<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 3<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 2<br>CMT        | CMT clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                   |
| 1<br>EWM        | EWM clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                   |
| 0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 12.2.13 System Clock Gating Control Register 5 (SIM\_SCGC5)

Address: 4004\_7000h base + 1038h offset = 4004\_8038h

**SIM\_SCGC5 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 18<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 17–15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 14<br>PORTF       | PORTF clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 13<br>PORTE       | PORTE clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 12<br>PORTD       | PORTD clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 11<br>PORTC       | PORTC clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 10<br>PORTB       | PORTB clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |

Table continues on the next page...

### SIM\_SCGC5 field descriptions (continued)

| Field                 | Description   |
|-----------------------|---|
| 9<br>PORTA            | PORTA clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |
| 8<br>Reserved         | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 7<br>Reserved         | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 6<br>Reserved         | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 5<br>TSI              | TSI clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                   |
| 4<br>Reserved         | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 3<br>DRYICESECRE<br>G | Dryice secure storage clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled. |
| 2<br>DRYICE           | Dryice clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                |
| 1<br>Reserved         | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 0<br>LPTIMER          | LPTMR clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                 |

### 12.2.14 System Clock Gating Control Register 6 (SIM\_SCGC6)

Address: 4004\_7000h base + 103Ch offset = 4004\_803Ch

|       |      |    |       |       |      |    |      |      |     |     |        |          |    |         |         |    |
|-------|------|----|-------|-------|------|----|------|------|-----|-----|--------|----------|----|---------|---------|----|
| Bit   | 31   | 30 | 29    | 28    | 27   | 26 | 25   | 24   | 23  | 22  | 21     | 20       | 19 | 18      | 17      | 16 |
| R     | 0    | 1  |       |       |      | 0  |      |      |     |     |        |          | 0  |         |         | 0  |
| W     |      |    | RTC   | ADC2  | ADC0 |    | FTM1 | FTM0 | PIT | PDB | USBDCD | USBHS    |    | CRC     |         |    |
| Reset | 0    | 1  | 0     | 0     | 0    | 0  | 0    | 0    | 0   | 0   | 0      | 0        | 0  | 0       | 0       | 0  |
| Bit   | 15   | 14 | 13    | 12    | 11   | 10 | 9    | 8    | 7   | 6   | 5      | 4        | 3  | 2       | 1       | 0  |

| 3<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 2<br>DMAMUX1      | DMAMUX1 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.               |

*Table continues on the next page...*

**SIM\_SCGC6 field descriptions (continued)**

| Field         | Description   |
|---------------|---|
| 1<br>DMAMUX0  | DMAMUX0 clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.               |
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 1. |

**12.2.15 System Clock Gating Control Register 7 (SIM\_SCGC7)**

Address: 4004\_7000h base + 1040h offset = 4004\_8040h

**SIM\_SCGC7 field descriptions**

| Field            | Description   |
|------------------|---|
| 31–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 3<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 2<br>MPU         | MPU clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.                   |
| 1<br>DMA         | DMA controller clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.        |
| 0<br>FLEXBUS     | FlexBus controller clock gate control<br>0 Clock is disabled.<br>1 Clock is enabled.    |

## 12.2.16 System Clock Divider Register 1 (SIM\_CLKDIV1)

### NOTE

The CLKDIV1 register cannot be written to when the device is in VLPR mode. The OUTDIV[1:4] bitfields reset only for power-on reset and are unaffected by other reset types.

Address: 4004\_7000h base + 1044h offset = 4004\_8044h

|       |         |    |    |    |         |    |    |    |         |    |    |    |         |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|---------|----|----|----|---------|----|----|----|---------|----|----|----|---------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31      | 30 | 29 | 28 | 27      | 26 | 25 | 24 | 23      | 22 | 21 | 20 | 19      | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | OUTDIV1 |    |    |    | OUTDIV2 |    |    |    | OUTDIV3 |    |    |    | OUTDIV4 |    |    |    | 0  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     | x*      |    |    |    | x*      |    |    |    | x*      |    |    |    | x*      |    |    |    | 0  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | x*      | x* | x* | x* | x*      | x* | x* | x* | x*      | x* | x* | x* | x*      | x* | x* | x* | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

\* Notes:

- x = Undefined at reset.

### SIM\_CLKDIV1 field descriptions

| Field            | Description  |
|------------------|--|
| 31–28<br>OUTDIV1 | <p>Clock 1 output divider value</p> <p>This field sets the divide value for the core/system clock. At the end of reset, it is loaded with either 0000 or 0111 depending on FTFE_FOPT[LPBOOT].</p> <p>0000 Divide-by-1.<br/>           0001 Divide-by-2.<br/>           0010 Divide-by-3.<br/>           0011 Divide-by-4.<br/>           0100 Divide-by-5.<br/>           0101 Divide-by-6.<br/>           0110 Divide-by-7.<br/>           0111 Divide-by-8.<br/>           1000 Divide-by-9.<br/>           1001 Divide-by-10.<br/>           1010 Divide-by-11.<br/>           1011 Divide-by-12.<br/>           1100 Divide-by-13.<br/>           1101 Divide-by-14.<br/>           1110 Divide-by-15.<br/>           1111 Divide-by-16.</p> |
| 27–24<br>OUTDIV2 | <p>Clock 2 output divider value</p> <p>This field sets the divide value for the peripheral clock. At the end of reset, it is loaded with either 0000 or 0111 depending on FTFE_FOPT[LPBOOT].</p> <p>0000 Divide-by-1.<br/>           0001 Divide-by-2.</p>   |

### 12.2.20 Unique Identification Register High (SIM\_UIDH)

Address: 4004\_7000h base + 1054h offset = 4004\_8054h

\* Notes:

- x = Undefined at reset.

### SIM\_UIDH field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>UID | Unique Identification<br><br>Unique identification for the device. |

## 12.2.21 Unique Identification Register Mid-High (SIM\_UIDMH)

Address: 4004\_7000h base + 1058h offset = 4004\_8058h

\* Notes:

- x = Undefined at reset.

### SIM\_UIDMH field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>UID | Unique Identification<br>Unique identification for the device. |

## 12.2.22 Unique Identification Register Mid Low (SIM\_UIDML)

Address: 4004\_7000h base + 105Ch offset = 4004\_805Ch

\* Notes:

- x = Undefined at reset.

### SIM\_UIDML field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>UID | Unique Identification<br>Unique identification for the device. |

### 12.2.23 Unique Identification Register Low (SIM\_UIDL)

Address: 4004\_7000h base + 1060h offset = 4004\_8060h

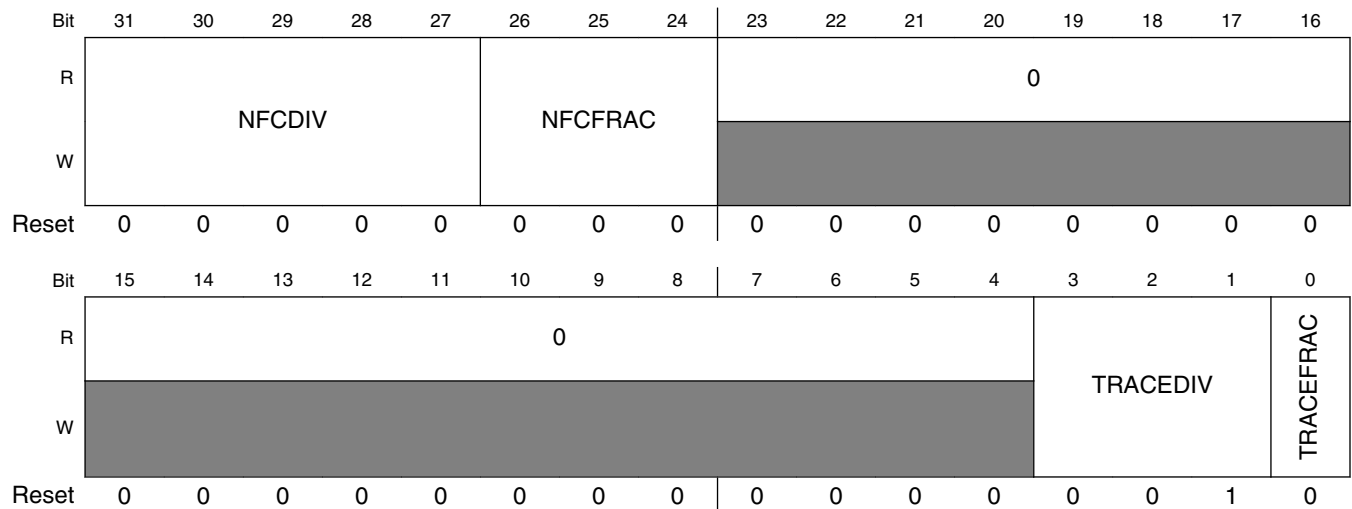

- \* Notes:
- x = Undefined at reset.

#### SIM\_UIDL field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>UID | Unique Identification<br>Unique identification for the device. |

### 12.2.24 System Clock Divider Register 4 (SIM\_CLKDIV4)

Address: 4004\_7000h base + 1068h offset = 4004\_8068h

#### SIM\_CLKDIV4 field descriptions

| Field           | Description   |
|-----------------|---|
| 31–27<br>NFCDIV | NFC clock divider divisor<br>This field sets the divide value for the fractional clock divider used as a source for NFC flash clock. The source clock for the fractional clock divider is set by the SOPT2[NFCSRC] bitfield.<br>Divider output clock = Divider input clock x ((NFCFRAC+1)/(NFCDIV+1)) |

Table continues on the next page...

### SIM\_CLKDIV4 field descriptions (continued)

| Field            | Description   |
|------------------|---|
|                  | <b>NOTE:</b> The reciprocal of $((\text{NFCFRAC}+1)/(\text{NFCDIV}+1))$ must be a multiple of 0.5. For example, $\text{NFCFRAC} = 1$ and $\text{NFCDIV} = 2$ is a valid setting, since the reciprocal is 1.5. However, $\text{NFCFRAC} = 2$ and $\text{NFCDIV}=7$ is not a valid setting, since the reciprocal is 2.6667.   |
| 26–24<br>NFCFRAC | NFC clock divider fraction<br><br>This field sets the fraction multiply value for the fractional clock divider used as a source for NFC flash clock. The source clock for the fractional clock divider is set by the $\text{SOPT2}[\text{NFCSRC}]$ bitfield.<br><br>Divider output clock = Divider input clock $\times ((\text{NFCFRAC}+1)/(\text{NFCDIV}+1))$<br><br><b>NOTE:</b> The reciprocal of $((\text{NFCFRAC}+1)/(\text{NFCDIV}+1))$ must be a multiple of 0.5. For example, $\text{NFCFRAC} = 1$ and $\text{NFCDIV} = 2$ is a valid setting, since the reciprocal is 1.5. However, $\text{NFCFRAC} = 2$ and $\text{NFCDIV}=7$ is not a valid setting, since the reciprocal is 2.6667. |

| 3–0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

# Chapter 13

## Reset Control Module (RCM)

### 13.1 Introduction

Information found here describes the registers of the Reset Control Module (RCM). The RCM implements many of the reset functions for the chip. See the chip's reset chapter for more information.

See [AN4503: Power Management for Kinetis and ColdFire+ MCUs](#) for further details on using the RCM.

### 13.2 Reset memory map and register descriptions

The RCM Memory Map/Register Definition can be found here.

The Reset Control Module (RCM) registers provide reset status information and reset filter control.

#### NOTE

The RCM registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

**RCM memory map**

| Absolute address (hex) | Register name                                | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|--|-----------------|--------|-------------|----------------------------|
| 4007_F000              | System Reset Status Register 0 (RCM_SRS0)    | 8               | R      | 82h         | <a href="#">13.2.1/348</a> |
| 4007_F001              | System Reset Status Register 1 (RCM_SRS1)    | 8               | R      | 00h         | <a href="#">13.2.2/349</a> |
| 4007_F004              | Reset Pin Filter Control register (RCM_RPFC) | 8               | R/W    | 00h         | <a href="#">13.2.3/351</a> |
| 4007_F005              | Reset Pin Filter Width register (RCM_RPFW)   | 8               | R/W    | 00h         | <a href="#">13.2.4/352</a> |
| 4007_F007              | Mode Register (RCM_MR)                       | 8               | R      | 00h         | <a href="#">13.2.5/353</a> |

### 13.2.1 System Reset Status Register 0 (RCM\_SRS0)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

**NOTE**

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x82
- LVD (without POR) — 0x02
- VLLS mode wakeup due to  $\overline{\text{RESET}}$  pin assertion — 0x41
- VLLS mode wakeup due to other wakeup sources — 0x01
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 4007\_F000h base + 0h offset = 4007\_F000h

**13.2.2 System Reset Status Register 1 (RCM\_SRS1)**

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

**NOTE**

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x00
- LVD (without POR) — 0x00
- VLLS mode wakeup — 0x00
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 4007\_F000h base + 1h offset = 4007\_F001h

# Chapter 14

## System Mode Controller (SMC)

### 14.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The System Mode Controller (SMC) is responsible for sequencing the system into and out of all low-power Stop and Run modes.

Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the system to achieve the power consumption and functionality of that mode.

This chapter describes all the available low-power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The SMC is able to function during even the deepest low power modes.

See [AN4503: Power Management for Kinetis and ColdFire+ MCUs](#) for further details on using the SMC.

### 14.2 Modes of operation

The ARM CPU has three primary modes of operation:

- Run
- Sleep
- Deep Sleep

The WFI or WFE instruction is used to invoke Sleep and Deep Sleep modes. Run, Wait, and Stop are the common terms used for the primary operating modes of Freescale microcontrollers.

The following table shows the translation between the ARM CPU modes and the Freescale MCU power modes.

| ARM CPU mode | MCU mode |
|--------------|----------|
| Sleep        | Wait     |
| Deep Sleep   | Stop     |

Accordingly, the ARM CPU documentation refers to sleep and deep sleep, while the Freescale MCU documentation normally uses wait and stop.

In addition, Freescale MCUs also augment Stop, Wait, and Run modes in a number of ways. The power management controller (PMC) contains a run and a stop mode regulator. Run regulation is used in normal run, wait and stop modes. Stop mode regulation is used during all very low power and low leakage modes. During stop mode regulation, the bus frequencies are limited in the very low power modes.

The SMC provides the user with multiple power options. The Very Low Power Run (VLPR) mode can drastically reduce run time power when maximum bus frequency is not required to handle the application needs. From Normal Run mode, the Run Mode (RUNM) field can be modified to change the MCU into VLPR mode when limited frequency is sufficient for the application. From VLPR mode, a corresponding wait (VLPW) and stop (VLPS) mode can be entered.

Depending on the needs of the user application, a variety of stop modes are available that allow the state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. Several registers are used to configure the various modes of operation for the device.

The following table describes the power modes available for the device.

**Table 14-1. Power modes**

| Mode | Description  |
|------|--|
| RUN  | The MCU can be run at full speed and the internal supply is fully regulated, that is, in run regulation. This mode is also referred to as Normal Run mode.   |
| WAIT | The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate. Run regulation is maintained.   |
| STOP | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.   |
| VLPR | The core, system, bus, and flash clock maximum frequencies are restricted in this mode. See the Power Management chapter for details about the maximum allowable frequencies.  |
| VLPW | The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted. See the Power Management chapter for details on the maximum allowable frequencies. |
| VLPS | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.   |

*Table continues on the next page...*

**Table 14-1. Power modes (continued)**

| Mode  | Description  |
|-------|--|
| LLS   | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by reducing the voltage to internal logic. All system RAM contents, internal logic and I/O states are retained.   |
| VLLS3 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic. All system RAM contents are retained and I/O states are held. Internal logic states are not retained.  |
| VLLS2 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and the system RAM2 partition. The system RAM1 partition contents are retained in this mode. Internal logic states are not retained. <sup>1</sup> |
| VLLS1 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained.  |

1. See the devices' chip configuration details for the size and location of the system RAM partitions.

## 14.3 Memory map and register descriptions

Information about the registers related to the system mode controller can be found here.

Different SMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

### NOTE

The SMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

### NOTE

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

## SMC memory map

| Absolute address (hex) | Register name                               | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|---|-----------------|--------|-------------|----------------------------|

### 14.3.1 Power Mode Protection register (SMC\_PMPROT)

This register provides protection for entry into any low-power run or stop mode. The enabling of the low-power run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

The PMPROT register can be written only once after any system reset.

If the MCU is configured for a disallowed or reserved power mode, the MCU remains in its current power mode. For example, if the MCU is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the MCU is still in Normal Run mode.

#### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the Reset section details for more information.

Address: 4007\_E000h base + 0h offset = 4007\_E000h

Writes to this field are blocked if the protection level has not been enabled using the PMPROT register. After any system reset, this field is cleared by hardware on any successful write to the PMPROT register.</p> <p><b>NOTE:</b> When set to VLLSx, the VLLSM field in the VLLSCTRL register is used to further select the particular VLLS submode which will be entered.</p> <p><b>NOTE:</b></p> <p>000 Normal Stop (STOP)<br/>001 Reserved<br/>010 Very-Low-Power Stop (VLPS)<br/>011 Low-Leakage Stop (LLS)<br/>100 Very-Low-Leakage Stop (VLLSx)<br/>101 Reserved<br/>110 Reseved<br/>111 Reserved</p> |

### 14.3.3 VLLS Control Register (SMC\_VLLSCTRL)

The VLLSCTRL register provides various control bits allowing the user to fine tune power consumption during the stop mode selected by the STOPM field.

#### NOTE

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

### 14.3.4 Power Mode Status register (SMC\_PMSTAT)

PMSTAT is a read-only, one-hot register which indicates the current power mode of the system.

**NOTE**

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

Address: 4007\_E000h base + 3h offset = 4007\_E003h

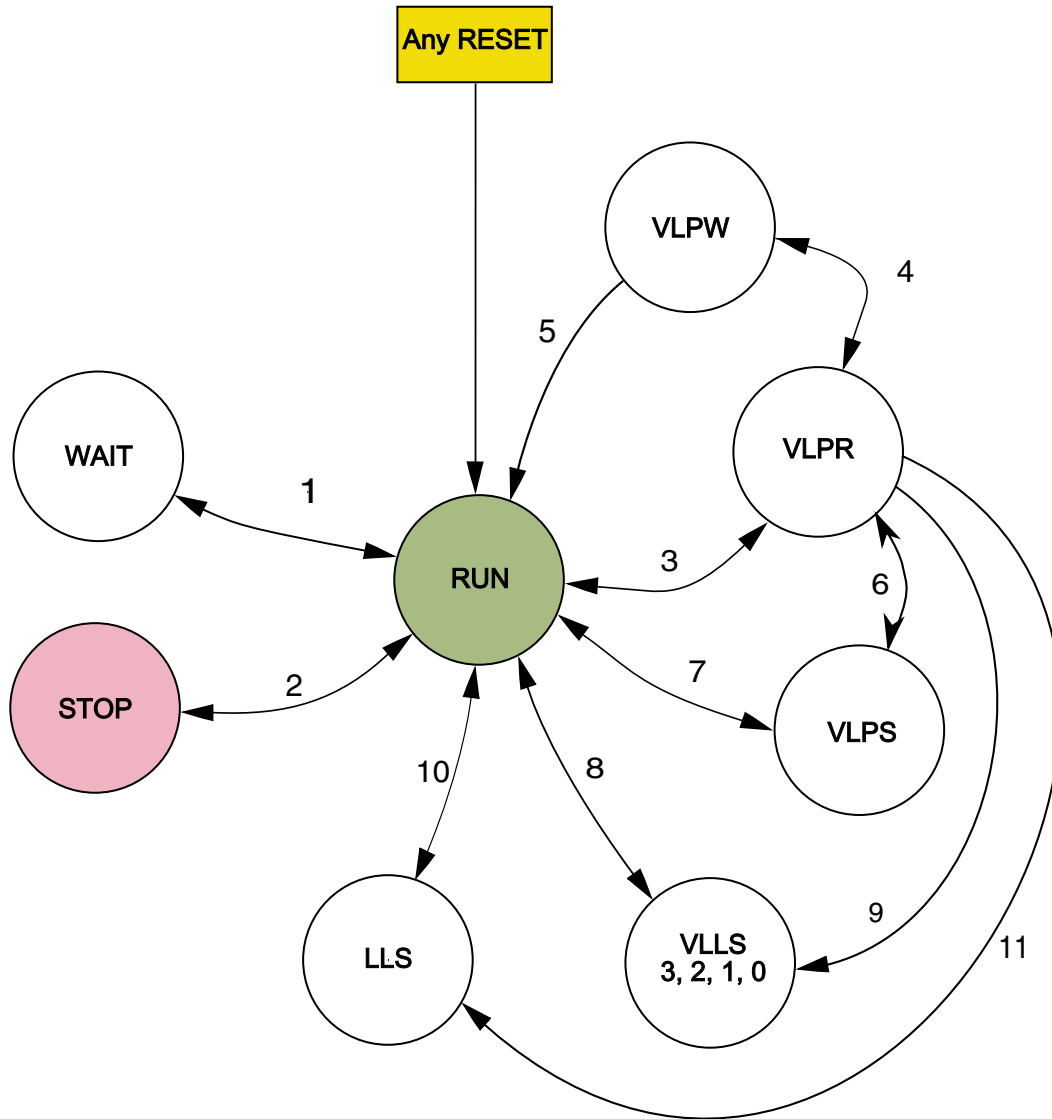

**SMC\_PMSTAT field descriptions**

| Field         | Description   |
|---------------|---|
| 7-0<br>PMSTAT | <p>Power Mode Status</p> <p><b>NOTE:</b> When debug is enabled, the PMSTAT will not update to STOP or VLPS</p> <p>0000_0001 Current power mode is RUN.<br/>                     0000_0010 Current power mode is STOP.<br/>                     0000_0100 Current power mode is VLPR.<br/>                     0000_1000 Current power mode is VLPW.<br/>                     0001_0000 Current power mode is VLPS.<br/>                     0010_0000 Current power mode is LLS.<br/>                     0100_0000 Current power mode is VLLS.<br/>                     1000_0000 Reserved</p> |

## 14.4 Functional description

### 14.4.1 Power mode transitions

The following figure shows the power mode state transitions available on the chip. Any reset always brings the MCU back to the normal RUN state.

**Figure 14-5. Power mode state diagram**

The following table defines triggers for the various state transitions shown in the previous figure.

**Table 14-7. Power mode transition triggers**

| Transition # | From | To   | Trigger conditions  |
|--------------|------|------|---|
| 1            | RUN  | WAIT | Sleep-now or sleep-on-exit modes entered with SLEEPDEEP clear, controlled in System Control Register in ARM core.<br>See note. <sup>1</sup> |
|              | WAIT | RUN  | Interrupt or Reset  |

*Table continues on the next page...*

**Table 14-7. Power mode transition triggers (continued)**

| Transition # | From | To   | Trigger conditions   |
|--------------|------|------|--|
| 2            | RUN  | STOP | PMCTRL[RUNM]=00, PMCTRL[STOPM]=000<br>Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.<br>See note. <sup>1</sup>   |
|              | STOP | RUN  | Interrupt or Reset   |
| 3            | RUN  | VLPR | The core, system, bus and flash clock frequencies and MCG clocking mode are restricted in this mode. See the Power Management chapter for the maximum allowable frequencies and MCG modes supported.<br>Set PMPROT[AVLP]=1, PMCTRL[RUNM]=10. |

|              | LLS   | RUN   | Wakeup from enabled LLWU input source or RESET pin.   |
| 11           | VLPR  | LLS   | PMPROT[ALLS]=1, PMCTRL[STOPM]=011, Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.                             |

1. If debug is enabled, the core clock remains to support debug.

## 14.4.2 Power mode entry/exit sequencing

When entering or exiting low-power modes, the system must conform to an orderly sequence to manage transitions safely.

The SMC manages the system's entry into and exit from all power modes. This diagram illustrates the connections of the SMC with other system components in the chip that are necessary to sequence the system through all power modes.

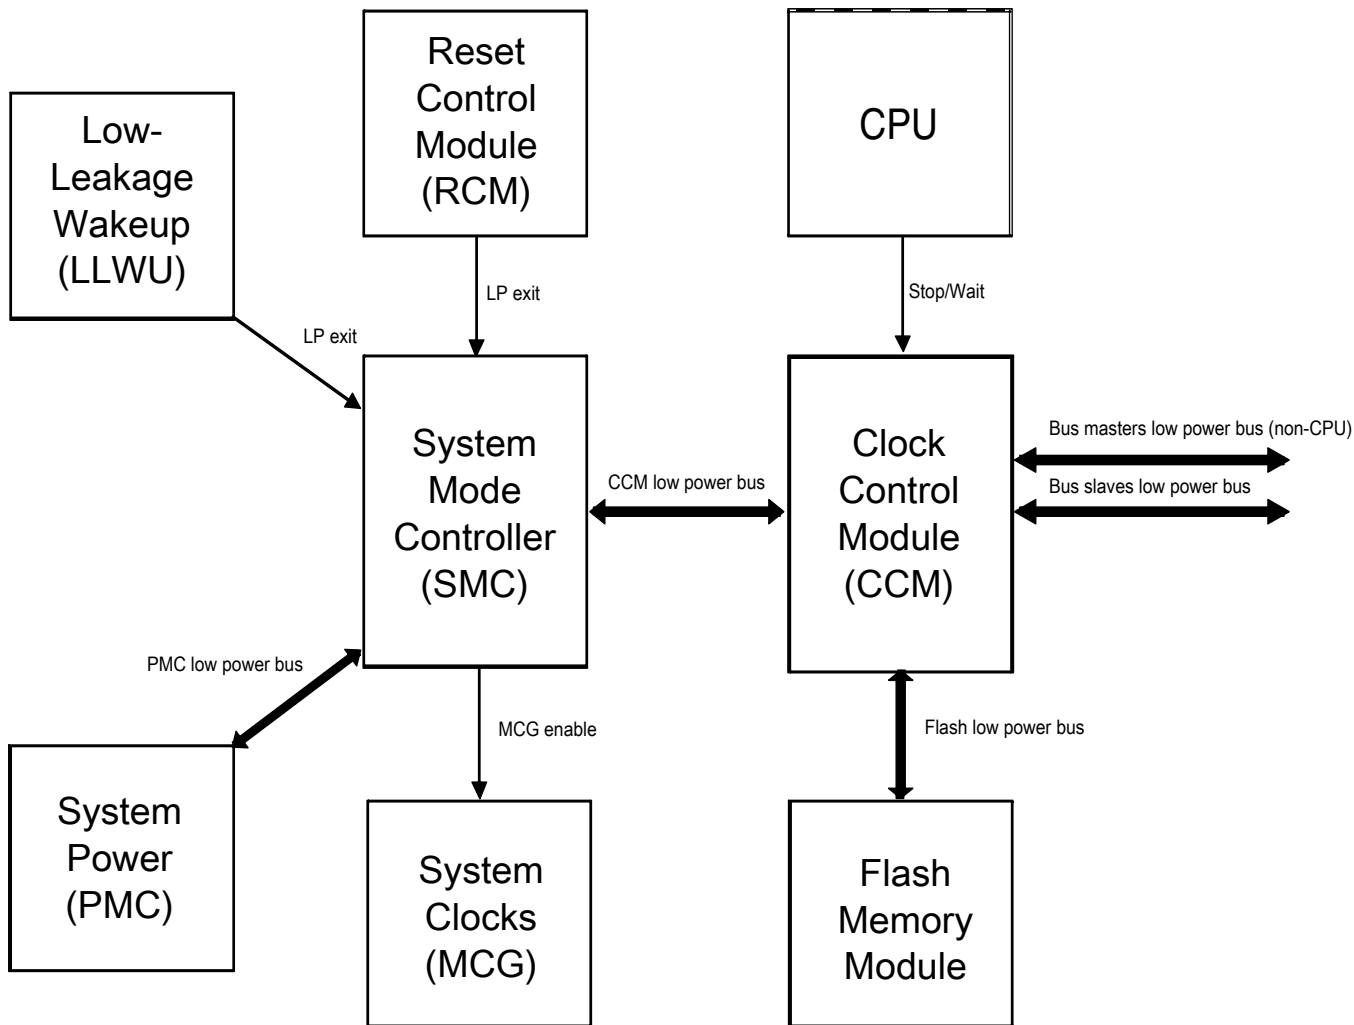

Figure 14-6. Low-power system components and connections

### 14.4.2.1 Stop mode entry sequence

Entry into a low-power stop mode (Stop, VLPS, LLS, VLLSx) is initiated by CPU execution of the WFI instruction. After the instruction is executed, the following sequence occurs:

1. The CPU clock is gated off immediately.

2. Requests are made to all non-CPU bus masters to enter Stop mode.
3. After all masters have acknowledged they are ready to enter Stop mode, requests are made to all bus slaves to enter Stop mode.
4. After all slaves have acknowledged they are ready to enter Stop mode, all system and bus clocks are gated off.
5. Clock generators are disabled in the MCG.
6. The on-chip regulator in the PMC and internal power switches are configured to meet the power consumption goals for the targeted low-power mode.

#### 14.4.2.2 Stop mode exit sequence

Exit from a low-power stop mode is initiated either by a reset or an interrupt event. The following sequence then executes to restore the system to a run mode (RUN or VLPR):

1. The on-chip regulator in the PMC and internal power switches are restored.
2. Clock generators are enabled in the MCG.
3. System and bus clocks are enabled to all masters and slaves.
4. The CPU clock is enabled and the CPU begins servicing the reset or interrupt that initiated the exit from the low-power stop mode.

#### 14.4.2.3 Aborted stop mode entry

If an interrupt or a reset occurs during a stop entry sequence, the SMC can abort the transition early and return to RUN mode without completely entering the stop mode. An aborted entry is possible only if the reset or interrupt occurs before the PMC begins the transition to stop mode regulation. After this point, the interrupt or reset is ignored until the PMC has completed its transition to stop mode regulation. When an aborted stop mode entry sequence occurs, SMC\_PMCTRL[STOPA] is set to 1.

#### 14.4.2.4 Transition to wait modes

For wait modes (WAIT and VLPW), the CPU clock is gated off while all other clocking continues, as in RUN and VLPR mode operation. Some modules that support stop-in-wait functionality have their clocks disabled in these configurations.

### 14.4.2.5 Transition from stop modes to Debug mode

The debugger module supports a transition from STOP, WAIT, VLPS, and VLPW back to a Halted state when the debugger has been enabled. As part of this transition, system clocking is re-established and is equivalent to the normal RUN and VLPR mode clocking configuration.

### 14.4.3 Run modes

The run modes supported by this device can be found here.

- Run (RUN)
- Very Low-Power Run (VLPR)

#### 14.4.3.1 RUN mode

This is the normal operating mode for the device.

This mode is selected after any reset. When the ARM processor exits reset, it sets up the stack, program counter (PC), and link register (LR):

- The processor reads the start SP (SP\_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF\_FFFF.

To reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

#### 14.4.3.2 Very-Low Power Run (VLPR) mode

In VLPR mode, the on-chip voltage regulator is put into a stop mode regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

Before entering this mode, the following conditions must be met:

- The MCG must be configured in a mode which is supported during VLPR. See the Power Management details for information about these MCG modes.
- All clock monitors in the MCG must be disabled.
- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.

- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] is set to 10b to enter VLPR.
- Flash programming/erasing is not allowed.

### NOTE

Do not increase the clock frequency while in VLPR mode, because the regulator is slow in responding and cannot manage fast load transitions. In addition, do not modify the clock source in the MCG module or any clock divider registers. Module clock enables in the SIM can be set, but not cleared.

To reenter Normal Run mode, clear PMCTRL[RUNM]. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system is in run regulation and the MCU can run at full speed in any clock mode. If a higher execution frequency is desired, poll PMSTAT until it is set to RUN when returning from VLPR mode.

VLPR mode also provides the option to return to run regulation if any interrupt occurs. Implement this option by setting Low-Power Wakeup On Interrupt (LPWUI) in the PMCTRL register. Any reset always causes an exit from VLPR and returns the device to RUN mode after the MCU exits its reset flow. The RUNM bits are cleared by hardware on any interrupt when LPWUI is set or on any reset.

## 14.4.4 Wait modes

This device contains two different wait modes which are listed here.

- Wait
- Very-Low Power Wait (VLPW)

### 14.4.4.1 WAIT mode

WAIT mode is entered when the ARM core enters the Sleep-Now or Sleep-On-Exit modes while SLEEDEEP is cleared. The ARM CPU enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled. Clock gating to the peripheral is enabled via the SIM module.

When an interrupt request occurs, the CPU exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from WAIT mode, returning the device to normal RUN mode.

#### 14.4.4.2 Very-Low-Power Wait (VLPW) mode

VLPW is entered by the entering the Sleep-Now or Sleep-On-Exit mode while SLEEPDEEP is cleared and the MCU is in VLPR mode.

In VLPW, the on-chip voltage regulator remains in its stop regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules by clearing the peripherals' corresponding clock gating control bits in the SIM.

VLPR mode restrictions also apply to VLPW.

VLPW mode provides the option to return to fully-regulated normal RUN mode if any enabled interrupt occurs. This is done by setting PMCTRL[LPWUI]. Wait for the PMSTAT register to set to RUN before increasing the frequency.

If the LPWUI bit is clear, when an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

A system reset will cause an exit from VLPW mode, returning the device to normal RUN mode.

#### 14.4.5 Stop modes

This device contains a variety of stop modes to meet your application needs.

The stop modes range from:

- a stopped CPU, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down CPU, with only I/O and a small register file retained, very few asynchronous mode peripherals operating, while the remainder of the MCU is powered down.

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs and recovery time may be traded off.

**NOTE**

All clock monitors must be disabled before entering these low-power modes: Stop, VLPS, VLPR, VLPW, LLS, and VLLSx.

The various stop modes are selected by setting the appropriate fields in PMPROT and PMCTRL. The selected stop mode is entered during the sleep-now or sleep-on-exit entry with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The available stop modes are:

- Normal Stop (STOP)
- Very-Low Power Stop (VLPS)
- Low-Leakage Stop (LLS)
- Very-Low-Leakage Stop (VLLSx)

**14.4.5.1 STOP mode**

STOP mode is entered via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The MCG module can be configured to leave the reference clocks running.

A module capable of providing an asynchronous interrupt to the device takes the device out of STOP mode and returns the device to normal RUN mode. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode. When an interrupt request occurs, the CPU exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from STOP mode, returning the device to normal RUN mode via an MCU reset.

**14.4.5.2 Very-Low-Power Stop (VLPS) mode**

The two ways in which VLPS mode can be entered are listed here.

- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in VLPR mode and  $\text{PMCTRL}[\text{STOPM}] = 010$  or  $000$ .
- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in normal RUN mode and  $\text{PMCTRL}[\text{STOPM}] = 010$ . When VLPS is entered directly from RUN mode, exit to VLPR is disabled by hardware and the system will always exit back to RUN.

In VLPS, the on-chip voltage regulator remains in its stop regulation state as in VLPR.

A module capable of providing an asynchronous interrupt to the device takes the device out of VLPS and returns the device to VLPR mode, provided LPWUI is clear.

If LPWUI is set, the device returns to normal RUN mode upon an interrupt request. PMSTAT must be set to RUN before allowing the system to return to a frequency higher than that allowed in VLPR mode.

A system reset will also cause a VLPS exit, returning the device to normal RUN mode.

### 14.4.5.3 Low-Leakage Stop (LLS) mode

Low-Leakage Stop (LLS) mode can be entered from normal RUN or VLPR modes.

The MCU enters LLS mode if:

- In Sleep-Now or Sleep-On-Exit mode, SLEEPDEEP is set in the System Control Register in the ARM core, and
- The device is configured as shown in [Table 14-7](#).

In LLS, the on-chip voltage regulator is in stop regulation. Most of the peripherals are put in a state-retention mode that does not allow them to operate while in LLS.

Before entering LLS mode, the user should configure the Low-Leakage Wake-up (LLWU) module to enable the desired wake-up sources. The available wake-up sources in LLS are detailed in the chip configuration details for this device.

After wakeup from LLS, the device returns to normal RUN mode with a pending LLWU module interrupt. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wake-up flags to determine the source of the wakeup.

#### NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit Stop mode on an LLS recovery.

An asserted  $\overline{\text{RESET}}$  pin will cause an exit from LLS mode, returning the device to normal RUN mode. When LLS is exiting via the  $\overline{\text{RESET}}$  pin, RCM\_SRS0[PIN] and RCM\_SRS0[WAKEUP] are set.

### 14.4.5.4 Very-Low-Leakage Stop (VLLSx) modes

This device contains these very low leakage modes:

- VLLS3
- VLLS2
- VLLS1

VLLS<sub>x</sub> is often used in this document to refer to all of these modes.

All VLLS<sub>x</sub> modes can be entered from normal RUN or VLPR modes.

The MCU enters the configured VLLS mode if:

- In Sleep-Now or Sleep-On-Exit mode, the SLEEPDEEP bit is set in the System Control Register in the ARM core, and
- The device is configured as shown in [Table 14-7](#).

In VLLS, the on-chip voltage regulator is in its stop-regulation state while most digital logic is powered off.

Before entering VLLS mode, the user should configure the Low-Leakage Wake-up (LLWU) module to enable the desired wakeup sources. The available wake-up sources in VLLS are detailed in the chip configuration details for this device.

After wakeup from VLLS, the device returns to normal RUN mode with a pending LLWU interrupt. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wake-up flags to determine the source of the wake-up.

When entering VLLS, each I/O pin is latched as configured before executing VLLS. Because all digital logic in the MCU is powered off, all port and peripheral data is lost during VLLS. This information must be restored before PMC\_REGSC[ACKISO] is set.

An asserted  $\overline{\text{RESET}}$  pin will cause an exit from any VLLS mode, returning the device to normal RUN mode. When exiting VLLS via the  $\overline{\text{RESET}}$  pin, RCM\_SRS0[PIN] and RCM\_SRS0[WAKEUP] are set.

### 14.4.6 Debug in low power modes

When the MCU is secure, the device disables/limits debugger operation. When the MCU is unsecure, the ARM debugger can assert two power-up request signals:

- System power up, via SYSPWR in the Debug Port Control/Stat register
- Debug power up, via CDBGPWRUPREQ in the Debug Port Control/Stat register

When asserted while in RUN, WAIT, VLPR, or VLPW, the mode controller drives a corresponding acknowledge for each signal, that is, both CDBGPWRUPACK and CSYSPWRUPACK. When both requests are asserted, the mode controller handles attempts to enter STOP and VLPS by entering an emulated stop state. In this emulated stop state:

**functional description**

- the regulator is in run regulation,
- the MCG-generated clock source is enabled,
- all system clocks, except the core clock, are disabled,
- the debug module has access to core registers, and
- access to the on-chip peripherals is blocked.

No debug is available while the MCU is in LLS or VLLS modes. LLS is a state-retention mode and all debug operation can continue after waking from LLS, even in cases where system wakeup is due to a system reset event.

Entering into a VLLS mode causes all of the debug controls and settings to be powered off. To give time to the debugger to sync with the MCU, the MDM AP Control Register includes a Very-Low-Leakage Debug Request (VLLDBGREQ) bit that is set to configure the Reset Controller logic to hold the system in reset after the next recovery from a VLLS mode. This bit allows the debugger time to reinitialize the debug module before the debug session continues.

The MDM AP Control Register also includes a Very Low Leakage Debug Acknowledge (VLLDBGACK) bit that is set to release the ARM core being held in reset following a VLLS recovery. The debugger reinitializes all debug IP, and then asserts the VLLDBGACK control bit to allow the RCM to release the ARM core from reset and allow CPU operation to begin.

The VLLDBGACK bit is cleared by the debugger (or can be left set as is) or clears automatically due to the reset generated as part of the next VLLS recovery.

# Chapter 15

## Power Management Controller (PMC)

### 15.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The power management controller (PMC) contains the internal voltage regulator, power on reset (POR), low voltage detect system (LVD), and high voltage detect system (HVD).

See [AN4503: Power Management for Kinetis and ColdFire+ MCUs](#) for further details on using the PMC.

### 15.2 Features

A list of included PMC features can be found [here](#).

- Internal voltage regulator
- Active POR providing brown-out detect
- Low-voltage detect supporting two low-voltage trip points with four warning levels per trip point

### 15.3 Low-voltage detect (LVD) system

This device includes a system to guard against low-voltage conditions. This protects memory contents and controls MCU system states during supply voltage variations.

The system is comprised of a power-on reset (POR) circuit and a LVD circuit with a user-selectable trip voltage: high ( $V_{LVDH}$ ) or low ( $V_{LVDL}$ ). The trip voltage is selected by `LVDS1[LVVDV]`. The LVD is disabled upon entering `VLPx`, `LLS`, and `VLLSx` modes.

Two flags are available to indicate the status of the low-voltage detect system:

- The Low Voltage Detect Flag in the Low Voltage Status and Control 1 Register (LVDSC1[LVDF]) operates in a level sensitive manner. LVDSC1[LVDF] is set when the supply voltage falls below the selected trip point (VLVD). LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC1[LVDF] remains set.
- The Low Voltage Warning Flag (LVWF) in the Low Voltage Status and Control 2 Register (LVDSC2[LVWF]) operates in a level sensitive manner. LVDSC2[LVWF] is set when the supply voltage falls below the selected monitor trip point (VLVW). LVDSC2[LVWF] is cleared by writing one to LVDSC2[LWACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC2[LVWF] remains set.

### 15.3.1 LVD reset operation

By setting LVDSC1[LVDRE], the LVD generates a reset upon detection of a low-voltage condition. The low-voltage detection threshold is determined by LVDSC1[LVDV]. After an LVD reset occurs, the LVD system holds the MCU in reset until the supply voltage rises above this threshold. The LVD field in the SRS register of the RCM module (RCM\_SRS[LVD]) is set following an LVD or power-on reset.

### 15.3.2 LVD interrupt operation

By configuring the LVD circuit for interrupt operation (LVDSC1[LVDIE] set and LVDSC1[LVDRE] clear), LVDSC1[LVDF] is set and an LVD interrupt request occurs upon detection of a low voltage condition. LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK].

### 15.3.3 Low-voltage warning (LVW) interrupt operation

The LVD system contains a Low-Voltage Warning Flag (LVWF) in the Low Voltage Detect Status and Control 2 Register to indicate that the supply voltage is approaching, but is above, the LVD voltage. The LVW also has an interrupt, which is enabled by setting LVDSC2[LVWIE]. If enabled, an LVW interrupt request occurs when LVDSC2[LVWF] is set. LVDSC2[LVWF] is cleared by writing 1 to LVDSC2[LWACK].

LVVSC2[LVVW] selects one of the four trip voltages:

- Highest:  $V_{LVW4}$
- Two mid-levels:  $V_{LVW3}$  and  $V_{LVW2}$
- Lowest:  $V_{LVW1}$

## 15.4 I/O retention

When in LLS mode, the I/O pins are held in their input or output state.

Upon wakeup, the PMC is re-enabled, goes through a power up sequence to full regulation, and releases the logic from state retention mode. The I/O are released immediately after a wake-up or reset event. In the case of LLS exit via a RESET pin, the I/O default to their reset state.

When in VLLS modes, the I/O states are held on a wake-up event (with the exception of wake-up by reset event) until the wake-up has been acknowledged via a write to REGSC[ACKISO]. In the case of VLLS exit via a RESET pin, the I/O are released and default to their reset state. In this case, no write to REGSC[ACKISO] is needed.

## 15.5 Memory map and register descriptions

Details about the PMC registers can be found here.

### NOTE

Different portions of PMC registers are reset only by particular reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

The PMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

### PMC memory map

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value | Section/page               |

| 4007_D001              | Low Voltage Detect Status And Control 2 register (PMC_LVDSC2) | 8               | R/W    | 00h         | <a href="#">15.5.2/379</a> |
| 4007_D002              | Regulator Status And Control register (PMC_REGSC)             | 8               | R/W    | 04h         | <a href="#">15.5.3/380</a> |

## 15.5.1 Low Voltage Detect Status And Control 1 register (PMC\_LVDSC1)

This register contains status and control bits to support the low voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC1 settings. To protect systems that must have LVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC\_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact LVD trip voltages.

### NOTE

The LVDV bits are reset solely on a POR Only event. The register's other bits are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

Address: 4007\_D000h base + 0h offset = 4007\_D000h

| Bit   | 7    | 6      | 5     | 4     | 3 | 2 | 1    | 0 |
|-------|------|--------|-------|-------|---|---|------|---|

### 15.5.2 Low Voltage Detect Status And Control 2 register (PMC\_LVDSC2)

This register contains status and control bits to support the low voltage warning function.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC2 settings.

See the device's data sheet for the exact LVD trip voltages.

#### NOTE

The LVW trip voltages depend on LVWV and LVDV.

#### NOTE

LVWV is reset solely on a POR Only event. The other fields of the register are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

### 15.5.3 Regulator Status And Control register (PMC\_REGSC)

The PMC contains an internal voltage regulator. The voltage regulator design uses a bandgap reference that is also available through a buffer as input to certain internal peripherals, such as the CMP and ADC. The internal regulator provides a status bit (REGONS) indicating the regulator is in run regulation.

### NOTE

This register is reset on Chip Reset Not VLLS and by reset types that trigger Chip Reset not VLLS. See the Reset section details for more information.

Address: 4007\_D000h base + 2h offset = 4007\_D002h

|       |   |   |          |   |        |        |          |      |

# Chapter 16

## Low-Leakage Wakeup Unit (LLWU)

### 16.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The LLWU module allows the user to select up to 16 external pins and up to 8 internal modules as interrupt wake-up sources from low-leakage power modes.

The input sources are described in the device's chip configuration details. Each of the available wake-up sources can be individually enabled.

The  $\overline{\text{RESET}}$  pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit both LLS and VLLS through a reset flow.

The LLWU\_RST[LLRSTE] bit must be set to allow an exit from low-leakage modes via the  $\overline{\text{RESET}}$  pin. On a device where the  $\overline{\text{RESET}}$  pin is shared with other functions, the explicit port mux control register must be set for the  $\overline{\text{RESET}}$  pin before the  $\overline{\text{RESET}}$  pin can be used as a low-leakage reset source.

The LLWU module also includes optional digital pin filters: two for the external wakeup pins and one for the  $\overline{\text{RESET}}$  pin.

#### 16.1.1 Features

The LLWU module features include:

- Support for up to 16 external input pins and up to 8 internal modules with individual enable bits for MCU interrupt from low leakage modes
- Input sources may be external pins or from internal peripherals capable of running in LLS or VLLS. See the chip configuration information for wakeup input sources for this device.

- External pin wake-up inputs, each of which is programmable as falling-edge, rising-edge, or any change
- Wake-up inputs that are activated after MCU enters a low-leakage power mode
- Optional digital filters provided to qualify an external pin detect and  $\overline{\text{RESET}}$  pin detect.

## 16.1.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from LLS, the LLWU is immediately disabled. After recovery from VLLS, the LLWU continues to detect wake-up events until the user has acknowledged the wake-up via a write to PMC\_REGSC[ACKISO].

### 16.1.2.1 LLS mode

Wake-up events due to external pin inputs (LLWU\_Px) and internal module interrupt inputs (LLWU\_MxIF) result in an interrupt flow when exiting LLS. A reset event due to  $\overline{\text{RESET}}$  pin assertion results in a reset flow when exiting LLS.

#### NOTE

The LLWU interrupt must not be masked by the interrupt controller to avoid a scenario where the system does not fully exit Stop mode on an LLS recovery.

### 16.1.2.2 VLLS modes

All wakeup and reset events result in VLLS exit via a reset flow.

### 16.1.2.3 Non-low leakage modes

The LLWU is not active in all non-low leakage modes where detection and control logic are in a static state. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When the  $\overline{\text{RESET}}$  pin filter or wake-up pin filters are enabled, filter operation begins immediately. If a low leakage mode is entered within five LPO clock cycles of an active edge, the edge event will be detected by the LLWU. For  $\overline{\text{RESET}}$  pin filtering, this means that there is no restart to the minimum LPO cycle duration as the filtering transitions from a non-low leakage filter, which is implemented in the RCM, to the LLWU filter.

### 16.1.2.4 Debug mode

When the chip is in Debug mode and then enters LLS or a VLLSx mode, no debug logic works in the fully-functional low-leakage mode. Upon an exit from the LLS or VLLSx mode, the LLWU becomes inactive.

### 16.1.3 Block diagram

The following figure is the block diagram for the LLWU module.

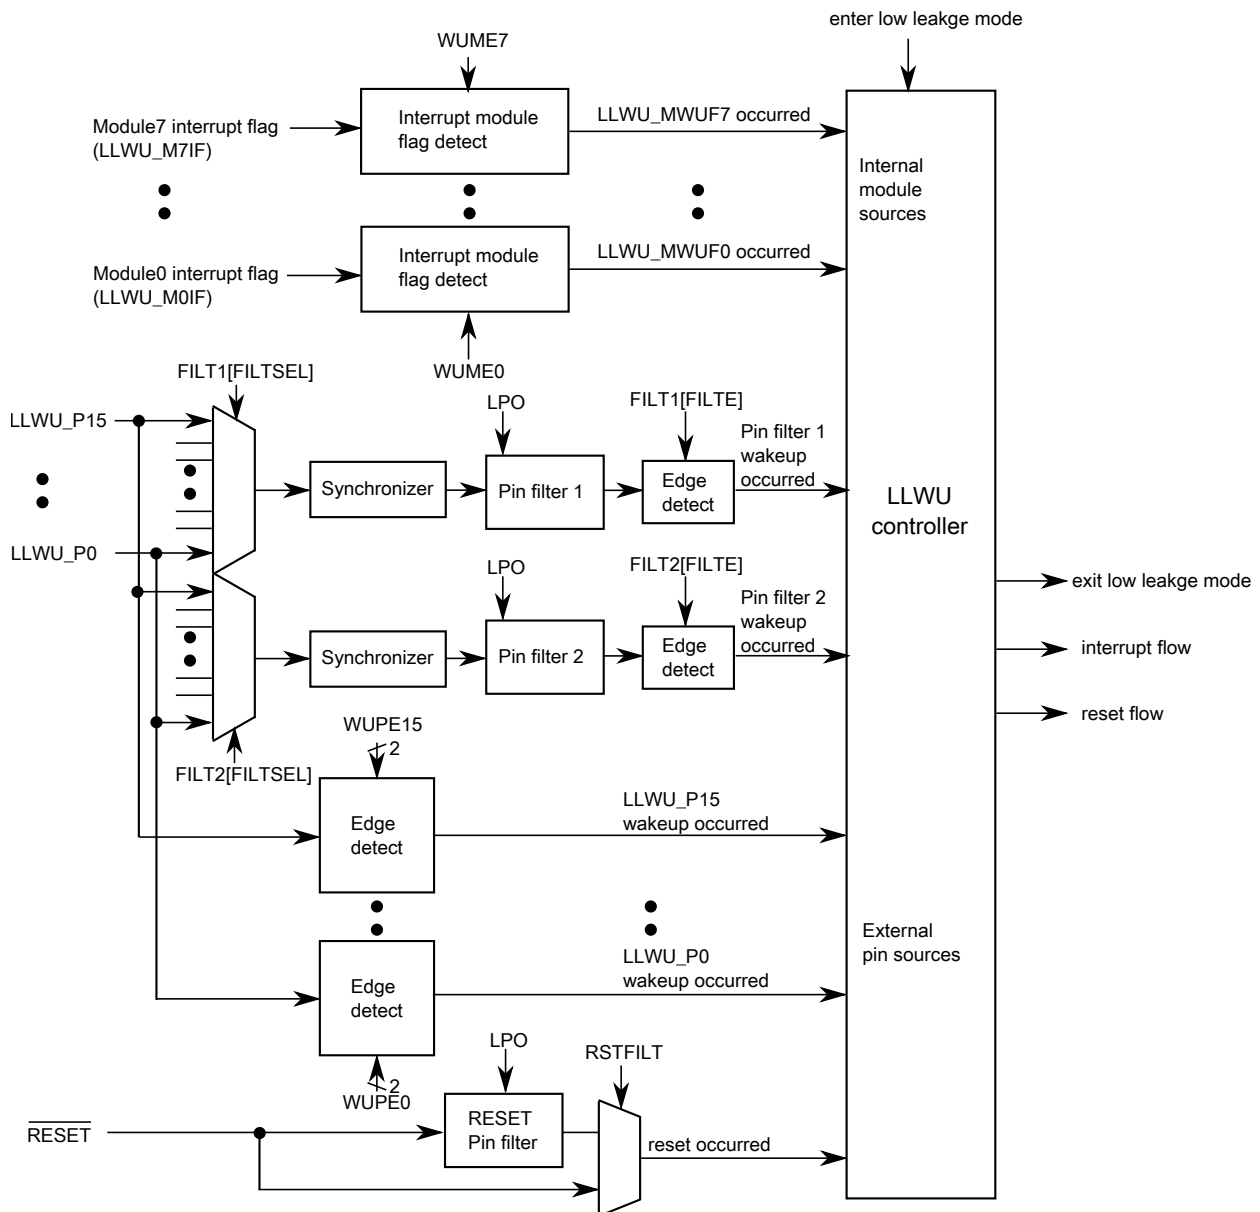

Figure 16-1. LLWU block diagram

## 16.2 LLWU signal descriptions

The signal properties of LLWU are shown in the table found here.

The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

**Table 16-1. LLWU signal descriptions**

| Signal  | Description               | I/O |
|---------|---------------------------|-----|
| LLWU_Pn | Wakeup inputs (n = 0-15 ) | I   |

## 16.3 Memory map/register definition

The LLWU includes the following registers:

- Wake-up source enable registers
  - Enable external pin input sources
  - Enable internal peripheral interrupt sources
- Wake-up flag registers
  - Indication of wakeup source that caused exit from a low-leakage power mode includes external pin or internal module interrupt
- Wake-up pin filter enable registers
- $\overline{\text{RESET}}$  pin filter enable register

### NOTE

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. Each register's displayed reset value represents this subset of reset types. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS. For more information about the types of reset on this chip, refer to the [Introduction](#) details.

## LLWU memory map

| Absolute address (hex) | Register name                           | Width (in bits) | Access | Reset value | Section/page                |

### 16.3.1 LLWU Pin Enable 1 register (LLWU\_PE1)

LLWU\_PE1 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P3–LLWU\_P0.

#### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

### 16.3.4 LLWU Pin Enable 4 register (LLWU\_PE4)

LLWU\_PE4 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P15–LLWU\_P12.

#### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

**16.3.5 LLWU Module Enable register (LLWU\_ME)**

LLWU\_ME contains the bits to enable the internal module flag as a wakeup input source for inputs MWUF7–MWUF0.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset

types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

**16.3.6 LLWU Flag 1 register (LLWU\_F1)**

LLWU\_F1 contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

### 16.3.7 LLWU Flag 2 register (LLWU\_F2)

LLWU\_F2 contains the wakeup flags indicating which wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

#### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

### 16.3.8 LLWU Flag 3 register (LLWU\_F3)

LLWU\_F3 contains the wakeup flags indicating which internal wakeup source caused the MCU to exit LLS or VLLS mode. For LLS, this is the source causing the CPU interrupt flow. For VLLS, this is the source causing the MCU reset flow.

For internal peripherals that are capable of running in a low-leakage power mode, such as a real time clock module or CMP module, the flag from the associated peripheral is accessible as the MWUFx bit. The flag will need to be cleared in the peripheral instead of writing a 1 to the MWUFx bit.

### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 16.4 Functional description

This low-leakage wakeup unit (LLWU) module allows internal peripherals and external input pins as a source of wakeup from low-leakage modes.

It is operational only in LLS and VLLSx modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

When an external pin is enabled as a wakeup source, the pin must be configured as an input pin.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin, either wakeup or  $\overline{\text{RESET}}$ , is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. Two wakeup detect filters are available for selected external pins. A separate reset filter is on the  $\overline{\text{RESET}}$  pin. Glitch filtering is not provided on the internal modules.

For internal module interrupts, the WUMEx bit enables the associated module interrupt as a wakeup source.

### 16.4.1 LLS mode

Wakeup events triggered from either an external pin input or an internal module interrupt, result in a CPU interrupt flow to begin user code execution.

An LLS reset event due to RESET pin assertion causes an exit via a system reset. State retention data is lost, and the I/O states return to their reset state. The RCM\_SRS[WAKEUP] and RCM\_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

### 16.4.2 VLLS modes

For any wakeup from VLLS, recovery is always via a reset flow and RCM\_SRS[WAKEUP] is set indicating the low-leakage mode was active. State retention data is lost and I/O will be restored after PMC\_REGSC[ACKISO] has been written.

A VLLS exit event due to  $\overline{\text{RESET}}$  pin assertion causes an exit via a system reset. State retention data is lost and the I/O states immediately return to their reset state. The RCM\_SRS[WAKEUP] and RCM\_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

### 16.4.3 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering LLS or VLLSx mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to LLS or VLLSx mode.

After enabling an external pin filter or changing the source pin, wait at least five LPO clock cycles before entering LLS or VLLSx mode to allow the filter to initialize.

#### NOTE

After recovering from a VLLS mode, user must restore chip configuration before clearing PMC\_REGSC[ACKISO]. In particular, pin configuration for enabled LLWU wake-up pins must be restored to avoid any LLWU flag from being falsely set when PMC\_REGSC[ACKISO] is cleared.

The signal selected as a wake-up source pin must be a digital pin, as selected in the pin mux control.

# Chapter 17

## Miscellaneous Control Module (MCM)

### 17.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

#### 17.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Control and counting logic for embedded trace buffer (ETB) almost full
- Error status and interrupts for the cache write buffer
- Error status and interrupts for the core's floating-point unit (FPU)

### 17.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

### MCM memory map

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value                 | Section/page                |
|------------------------|---|-----------------|--------|-----------------------------|-----------------------------|

## 17.2.1 Crossbar Switch (AXBS) Slave Configuration (MCM\_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device’s crossbar switch.

Address: E008\_0000h base + 8h offset = E008\_0008h

### MCM\_PLASC field descriptions

| Field            | Description   |
|------------------|---|
| 15–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>ASC       | Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port.<br><br>0 A bus slave connection to AXBS input port <i>n</i> is absent<br>1 A bus slave connection to AXBS input port <i>n</i> is present |

## 17.2.2 Crossbar Switch (AXBS) Master Configuration (MCM\_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008\_0000h base + Ah offset = E008\_000Ah

|       |              |    |    |    |    |    |   |   |     |   |   |   |   |   |   |   |
|-------|--------------|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|
| Bit   | 15           | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | 0            |    |    |    |    |    |   |   | AMC |   |   |   |   |   |   |   |
| Write | [Greyed out] |    |    |    |    |    |   |   |     |   |   |   |   |   |   |   |

### MCM\_PLAMC field descriptions

| Field            | Description   |
|------------------|---|
| 15–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>AMC       | Each bit in the AMC field indicates whether there is a corresponding connection to the AXBS master input port.<br><br>0 A bus master connection to AXBS input port <i>n</i> is absent<br>1 A bus master connection to AXBS input port <i>n</i> is present |

## 17.2.3 Control Register (MCM\_CR)

CR defines the arbitration and protection schemes for the two system RAM arrays.

### NOTE

Bits 23-22, 19-0 are undefined after reset.

Address: E008\_0000h base + Ch offset = E008\_000Ch

|       |              |         |         |    |         |         |          |         |          |          |          |          |          |          |          |          |

| 9<br>Reserved     | This field is reserved. |
| 8–0<br>Reserved   | This field is reserved. |

## 17.2.4 Interrupt Status and Control Register (MCM\_ISCR)

The MCM\_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, bus errors associated with the core's cache write buffer, and events associated with the debug ETB module. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Address: E008\_0000h base + 10h offset = E008\_0010h

| 10–0<br>COUNTER   | Byte Count Counter Value<br><br>Indicates the current 0-mod-4 value of the counter.     |

## 17.2.8 Fault address register (MCM\_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM\_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM\_ISCR[CWBER] indicator cleared, the MCM\_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. Attempted writes have no effect.

Address: E008\_0000h base + 20h offset = E008\_0020h

- \* Notes:
- x = Undefined at reset.

### MCM\_FADR field descriptions

| Field           | Description   |
|-----------------|---------------|
| 31–0<br>ADDRESS | Fault address |

## 17.2.9 Fault attributes register (MCM\_FATR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting attributes are captured in the MCM\_FATR register.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. Attempted writes have no effect.

Address: E008\_0000h base + 24h offset = E008\_0024h

memory map/register descriptions

### 17.2.10 Fault data register (MCM\_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM\_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM\_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes have no effect.

Address: E008\_0000h base + 28h offset = E008\_0028h

- \* Notes:
- x = Undefined at reset.

### MCM\_FDR field descriptions

| Field        | Description |
|--------------|-------------|
| 31–0<br>DATA | Fault data  |

### 17.2.11 Process ID register (MCM\_PID)

This register drives the M0\_PID and M1\_PID values in the Memory Protection Unit(MPU). System software loads this register before passing control to a given user mode process. If the PID of the process does not match the value in this register, a bus error occurs. See the MPU chapter for more details.

Address: E008\_0000h base + 30h offset = E008\_0030h

#### MCM\_PID field descriptions

| Field            | Description   |
|------------------|---|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 7–0<br>PID       | M0_PID And M1_PID For MPU<br>Drives the M0_PID and M1_PID values in the MPU.            |

## 17.3 Functional description

This section describes the functional description of MCM module.

### 17.3.1 Interrupts

The MCM generates two interrupt requests:

- Non-maskable interrupt
- Normal interrupt

#### 17.3.1.1 Non-maskable interrupt

The MCM's NMI is generated if:

- ISCR[ETBN] is set, when
  - The ETB counter is enabled, ETBCC[CNTEN] = 1
  - The ETB count expires
  - The response to counter expiration is an NMI, MCM\_ETBCC[RSPT] = 10

### 17.3.1.2 Normal interrupt

The MCM's normal interrupt is generated if any of the following is true:

- ISCR[ETBI] is set, when
  - The ETB counter is enabled, ETBCC[*CNTEN*] = 1
  - The ETB count expires
  - The response to counter expiration is a normal interrupt, ETBCC[*RSPT*] = 01
- Cache write buffer error interrupt is enabled (CWBEE) and a cache write buffer error occurs (CWBEE)
- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FDZCE) and an invalid occurs (FDZC)

### 17.3.1.3 Determining source of the normal interrupt

To determine the exact source of the normal interrupt qualify the interrupt status flags with the corresponding interrupt enable bits.

1. Form  $MCM\_ISCR[31:16] \&\& MCM\_ISCR[15:0]$
2. Search the result for asserted flags, which indicate the exact interrupt sources

# Chapter 18

## Crossbar Switch (AXBS)

### 18.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

#### 18.1.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- 32-bit data bus
- Support for byte, 2-byte, 4-byte, and 16-byte burst transfers
- Operation at a 1-to-1 clock frequency with the bus masters
- Low-Power Park mode support

## 18.2 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a bus error interrupt.

### NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

#### 18.2.1 Priority Registers Slave (AXBS\_PRSn)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

#### NOTE

Valid values for the  $M_n$  priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to  $n-1$ , where  $n$  is the number of masters attached to the Crossbar Switch. Other values will result in an error.

#### NOTE

See the chip-specific crossbar information for the reset value of this register.

### 18.2.2 Control Register (AXBS\_CRSn)

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

#### NOTE

See the chip-specific crossbar information for the reset value of this register.

## 18.3 Functional Description

### 18.3.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS<sub>n</sub>[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS<sub>n</sub>[PCTL].

### 18.3.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCR<sub>x</sub>[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCR<sub>x</sub>[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

### 18.3.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

#### 18.3.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

**Figure 18-28. Undefined length burst example**

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does

not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

### Note

Fixed-length burst accesses are not affected by the AULB bits.  
All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

### 18.3.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRSn). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

### NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

**Table 18-29. How the Crossbar Switch grants control of a slave port to a master**

| When   | Then the Crossbar Switch grants control to the requesting master  |
|--|---|
| Both of the following are true: <ul style="list-style-type: none"> <li>• The current master is not running a transfer.</li> <li>• The new requesting master's priority level is higher than that of the current master.</li> </ul>                                 | At the next clock edge  |
| Both of the following are true: <ul style="list-style-type: none"> <li>• The current master is running a fixed length burst transfer or a locked transfer.</li> <li>• The requesting master's priority level is higher than that of the current master.</li> </ul> | At the end of the burst transfer or locked transfer   |
| Both of the following are true: <ul style="list-style-type: none"> <li>• The current master is running an undefined length burst transfer.</li> <li>• The requesting master's priority level is higher than that of the current master.</li> </ul>                 | At the next arbitration point for the undefined length burst transfer<br><b>NOTE:</b> Arbitration points for an undefined length burst are defined in the MGPCR for each master.                |
| The requesting master's priority level is lower than the current master.   | At the conclusion of one of the following cycles: <ul style="list-style-type: none"> <li>• An IDLE cycle</li> <li>• A non-IDLE cycle to a location other than the current slave port</li> </ul> |

### 18.3.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

#### 18.3.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRSn), the crossbar switch responds with a bus error and the registers are not updated.

### 18.4 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

# Chapter 19

## Memory Protection Unit (MPU)

### 19.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The memory protection unit (MPU) provides hardware access control for all memory references generated in the device.

### 19.2 Overview

The MPU concurrently monitors all system bus transactions and evaluates their appropriateness using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with a protection error response.

#### 19.2.1 Block diagram

A simplified block diagram of the MPU module is shown in the following figure.

**Figure 19-1. MPU block diagram**

The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and the access protection error. For details of the access evaluation macro, see [Access evaluation macro](#).

## 19.2.2 Features

The MPU implements a two-dimensional hardware array of memory region descriptors and the crossbar slave ports to continuously monitor the legality of every memory reference generated by each bus master in the system.

The feature set includes:

- 16 program-visible 128-bit region descriptors, accessible by four 32-bit words each
  - Each region descriptor defines a modulo-32 byte space, aligned anywhere in memory

- Region sizes can vary from 32 bytes to 4 Gbytes
- Two access control permissions defined in a single descriptor word
  - Masters 0–3: read, write, and execute attributes for supervisor and user accesses
  - Masters 4–7: read and write attributes
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
- Alternate programming model view of the access control permissions word
- Priority given to granting permission over denying access for overlapping region descriptors
- Detects access protection errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the MPU inhibits the bus cycle being sent to the targeted slave device.
- Error registers, per slave port, capture the last faulting address, attributes, and other information
- Global MPU enable/disable control bit

### 19.3 Memory map/register definition

The programming model is partitioned into three groups:

- Control/status registers
- The data structure containing the region descriptors
- The alternate view of the region descriptor access control values

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined, that is, reserved, addresses, or with a non-supported access type, such as a write to a read-only register, or a read of a write-only register, generate an error termination.

The programming model can be accessed only in supervisor mode.

#### NOTE

See the chip configuration details for any chip-specific register information in this module.

### MPU memory map

### MPU\_CESR field descriptions

| Field             | Description  |
|-------------------|--|
| 31–24<br>SPERR    | <p>Slave Port n Error</p> <p>Indicates a captured error in EARn and EDRn. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error.</p> <p>The following shows the correspondence between the bit number and slave port number:</p> <ul style="list-style-type: none"> <li>• Bit 31 corresponds to slave port 0.</li> <li>• Bit 30 corresponds to slave port 1.</li> <li>• Bit 29 corresponds to slave port 2.</li> <li>• Bit 28 corresponds to slave port 3.</li> <li>• Bit 27 corresponds to slave port 4.</li> <li>• Bit 26 corresponds to slave port 5.</li> <li>• Bit 25 corresponds to slave port 6.</li> <li>• Bit 24 corresponds to slave port 7.</li> </ul> <p>0 No error has occurred for slave port n.<br/>1 An error has occurred for slave port n.</p> |
| 23<br>Reserved    | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 1.</p>  |
| 22–20<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 19–16<br>HRL      | <p>Hardware Revision Level</p> <p>Specifies the MPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.</p>   |
| 15–12<br>NSP      | <p>Number Of Slave Ports</p> <p>Specifies the number of slave ports connected to the MPU.</p>  |
| 11–8<br>NRGD      | <p>Number Of Region Descriptors</p> <p>Indicates the number of region descriptors implemented in the MPU.</p>  |

*Table continues on the next page...*

### MPU\_CESR field descriptions (continued)

| Field           | Description  |
|-----------------|--|
|                 | 0000 8 region descriptors<br>0001 12 region descriptors<br>0010 16 region descriptors  |
| 7–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 0<br>VLD        | Valid<br>Global enable/disable for the MPU.<br>0 MPU is disabled. All accesses from all bus masters are allowed.<br>1 MPU is enabled |

### 19.3.2 Error Address Register, slave port n (MPU\_EAR<sub>n</sub>)

When the MPU detects an access error on slave port n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR[SPERR] set. Additional information about the faulting access is captured in the corresponding EDR<sub>n</sub> at the same time. This register and the corresponding EDR<sub>n</sub> contain the most recent access error; there are no hardware interlocks with CESR[SPERR], as the error registers are always loaded upon the occurrence of each protection violation.

Address: 4000\_D000h base + 10h offset + (8d × i), where i=0d to 7d

#### MPU\_EAR<sub>n</sub> field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>EADDR | Error Address<br>Indicates the reference address from slave port n that generated the access error |

### 19.3.3 Error Detail Register, slave port n (MPU\_EDRn)

When the MPU detects an access error on slave port n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR[SPERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time. This register and the corresponding EARn register contain the most recent access error; there are no hardware interlocks with CESR[SPERR] as the error registers are always loaded upon the occurrence of each protection violation.

Address: 4000\_D000h base + 14h offset + (8d × i), where i=0d to 7d

### MPU\_EDR<sub>n</sub> field descriptions (continued)

| Field    | Description   |
|----------|---|
| 0<br>ERW | Error Read/Write<br><br>Indicates the access type of the faulting reference.<br><br>0 Read<br>1 Write |

### 19.3.4 Region Descriptor n, Word 0 (MPU\_RGD<sub>n</sub>\_WORD0)

The first word of the region descriptor defines the 0-modulo-32 byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGD<sub>n</sub>\_WORD3[VLD]).

Address: 4000\_D000h base + 400h offset + (16d × i), where i=0d to 15d

### MPU\_RGD<sub>n</sub>\_WORD0 field descriptions

| Field           | Description  |
|-----------------|--|
| 31–5<br>SRTADDR | Start Address<br><br>Defines the most significant bits of the 0-modulo-32 byte start address of the memory region. |
| 4–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                            |

### 19.3.5 Region Descriptor n, Word 1 (MPU\_RGDn\_WORD1)

The second word of the region descriptor defines the 31-modulo-32 byte end address of the memory region. Writes to this register clear the region descriptor’s valid bit (RGDn\_WORD3[VLD]).

Address: 4000\_D000h base + 404h offset + (16d × i), where i=0d to 15d

\* Notes:

- Reset value of RGD0\_WORD1 is FFFF\_FFFFh  
Reset value of RGD[1:15]\_WORD1 is 0000\_001Fh

#### MPU\_RGDn\_WORD1 field descriptions

| Field           | Description   |
|-----------------|---|
| 31–5<br>ENDADDR | End Address<br>Defines the most significant bits of the 31-modulo-32 byte end address of the memory region.<br><b>NOTE:</b> The MPU does not verify that ENDADDR ≥ SRTADDR. |
| 4–0<br>Reserved | This field is reserved.   |

### 19.3.6 Region Descriptor n, Word 2 (MPU\_RGDn\_WORD2)

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses, as well as the optional inclusion of a process identification field within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch

**memory map/register definition**

- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn\_WORD2 clear the region descriptor's valid bit (RGDn\_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

Address: 4000\_D000h base + 408h offset + (16d × i), where i=0d to 15d

|       |      |      |      |      |      |      |      |      |      |      |      |      |      |    |      |      |

## 19.4 Functional description

In this section, the functional operation of the MPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

### 19.4.1 Access evaluation macro

The basic operation of the MPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in the following figure, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD $n$ ) and performs two major functions:

- Region hit determination
- Detection of an access protection violation

The following figure shows a functional block diagram.

**Figure 19-106. MPU access evaluation macro**

### 19.4.1.1 Hit determination

To determine whether the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[31:5] >= RGDn_Word0[SRTADDR]) & (addr[31:5] <= RGDn_Word1[ENDADDR])) & RGDn_Word3[VLD]
```

where *addr* is the current reference address, *RGDn\_Word0[SRTADDR]* and *RGDn\_Word1[ENDADDR]* are the start and end addresses, and *RGDn\_Word3[VLD]* is the valid bit.

#### NOTE

The MPU does not verify that *ENDADDR* ≥ *SRTADDR*.

In addition to the comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. A process identifier hit term is formed as follows:

```
pid_hit = ~RGDn_Word2[MxPE] |
          ((current_pid |
           RGDn_Word3[PIDMASK]) == (RGDn_Word3[PID] | RGDn_Word3[PIDMASK]))
```

where the *current\_pid* is the selected process identifier from the current bus master, and *RGDn\_Word3[PID]* and *RGDn\_Word3[PIDMASK]* are the process identifier fields from region descriptor *n*. For bus masters that do not output a process identifier, the MPU forces the *pid\_hit* term to assert.

### 19.4.1.2 Privilege violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master and supervisor/user mode signals, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

**Table 19-106. Protection violation definition**

| Description            | MxUM |   |   | Protection violation?      |
|------------------------|------|---|---|----------------------------|
|                        | r    | w | x |                            |
| Instruction fetch read | —    | — | 0 | Yes, no execute permission |
|                        | —    | — | 1 | No, access is allowed      |
| Data read              | 0    | — | — | Yes, no read permission    |
|                        | 1    | — | — | No, access is allowed      |
| Data write             | —    | 0 | — | Yes, no write permission   |
|                        | —    | 1 | — | No, access is allowed      |

### 19.4.2 Putting it all together and error terminations

For each slave port monitored, the MPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports a protection error for three conditions:

- If the access does not hit in any region descriptor, a protection error is reported.
- If the access hits in a single region descriptor and that region signals a protection violation, a protection error is reported.
- If the access hits in multiple (overlapping) regions and all regions signal protection violations, a protection error is reported.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see [Application information](#).

### 19.4.3 Power management

Disabling the MPU by clearing CESR[VLD] minimizes power dissipation. To minimize the power dissipation of an enabled MPU, invalidate unused region descriptors by clearing the associated RGDn\_Word3[VLD] bits.

## 19.5 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGDn\_Word3[VLD]. Setting CESR[VLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire MPU is disabled (CESR[VLD]=0).

### Note

A region descriptor must be set to allow access to the MPU registers if further changes are needed.

## 19.6 Application information

In an operational system, interfacing with the MPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes. (Clearing RGDn\_Word3[VLD] deletes/removes an existing memory region.)
- Altering only access privileges—To not affect the valid bit, write to the alternate version of the access control word (RGDAACn), so there are no coherency issues involved with the update. When the write completes, the memory region's access rights switch instantaneously to the new value.
- Changing a region's start and end addresses—Write a minimum of three words to the region descriptor (RGDn\_Word{0,1,3}). Word 0 and 1 redefine the start and end addresses, respectively. Word 3 re-enables the region descriptor valid bit. In most situations, all four words of the region descriptor are rewritten.
- Accessing the MPU—Allocate a region descriptor to restrict MPU access to supervisor mode from a specific master.

- Detecting an access error—The current bus cycle is terminated with an error response and  $EAR_n$  and  $EDR_n$  capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading  $E\{A,D\}R_n$ .  $CESR[SPERR]$  signals which error registers contain captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters:

- The two processors: CP0, CP1
- Two DMA engines: DMA1, a traditional data movement engine transferring data between RAM and peripherals and DMA2, a second engine transferring data to/from the RAM only

Consider the following region descriptor assignments:

**Table 19-107. Overlapping region descriptor example**

| Region description    | RGDn | CP0 | CP1 | DMA1 | DMA2 |                  |
|-----------------------|------|-----|-----|------|------|------------------|
| CP0 code              | 0    | rwX | r-- | —    | —    | Flash            |
| CP1 code              | 1    | r-- | rwX | —    | —    |                  |
| CP0 data & stack      | 2    | rw- | —   | —    | —    | RAM              |
| CP0 → CP1 shared data | 2    | 3   | r-- | —    | —    |                  |
| CP1 → CP0 shared data | 4    |     |     |      |      |                  |
| CP1 data & stack      | 4    | —   | rw- | —    | —    |                  |
| Shared DMA data       | 5    | rw- | rw- | rw   | rw   |                  |
| MPU                   | 6    | rw- | rw- | —    | —    | Peripheral space |
| Peripherals           | 7    | rw- | rw- | rw   | —    |                  |

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map: flash, RAM, and peripheral space. Each region indicates the specific permissions for each of the four bus masters and this definition provides an appropriate set of shared, private and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1 and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has  $(rw- \mid r--)$  =  $(rw-)$  permissions, while CP1 has  $(--- \mid r--)$  =  $(r--)$  permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has  $(r-- \mid ---)$  =  $(r--)$  permission, while CP1 has  $(rw- \mid r--)$  =  $(rw-)$  permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the IPS bus is partitioned into two regions:

- One containing the MPU's programming model accessible only to the two processor cores
- The remaining peripheral region accessible to both processors and the traditional DMA1 master

This example shows one possible application of the capabilities of the MPU in a typical system.

## Chapter 20

# Peripheral Bridge (AIPS-Lite)

### 20.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 4 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

#### 20.1.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Programming model provides memory protection functionality

#### 20.1.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge performs a bus protocol conversion of the master transactions and generates the following as inputs to the peripherals:

- Module enables
- Module addresses
- Transfer attributes
- Byte enables
- Write data

The peripheral bridge selects and captures read data from the peripheral interface and returns it to the crossbar switch.

The register maps of the peripherals are located on 4-KB boundaries. Each peripheral is allocated one or more 4-KB block(s) of the memory map.

The AIPS-Lite module uses the data width of accessed peripheral to perform proper data byte lane routing; no bus decomposition (bus sizing) is performed.

## 20.2 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

**AIPS memory map**

#### 20.2.1 Master Privilege Register A (AIPSx\_MPRA)

The MPRA specifies identical 4-bit fields defining the access-privilege level associated with a bus master to various peripherals on the chip. The register provides one field per bus master.

#### NOTE

At reset, the default value loaded into the MPRA fields is chip-specific. See the chip configuration details for the value of a particular device.

A register field that maps to an unimplemented master or peripheral behaves as read-only-zero.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the chip-specific AIPS information.

## memory map/register definition

## 20.2.2 Peripheral Access Control Register (AIPSx\_PACRn)

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular peripheral. The mapping between a peripheral and its PACR field is shown in the table below. The peripheral assignment to each PACR is defined by the memory map slot that the peripheral is assigned to. See this chip's memory map for the assignment of a particular peripheral.

The following table shows the location of each peripheral slot's PACR field in the PACR registers.

| Offset | Register | [31:28] | [27:24] | [23:20] | [19:16] | [15:12] | [11:8] | [7:4]  | [3:0]  |
|--------|----------|---------|---------|---------|---------|---------|--------|--------|--------|
| 0x20   | PACRA    | PACR0   | PACR1   | PACR2   | PACR3   | PACR4   | PACR5  | PACR6  | PACR7  |
| 0x24   | PACRB    | PACR8   | PACR9   | PACR10  | PACR11  | PACR12  | PACR13 | PACR14 | PACR15 |

**NOTE**

The register field descriptions for PACR A-D, which control peripheral slots 0-31, are shown below. The following section, [Peripheral Access Control Register \(AIPS\\_PACR<sub>n</sub>\)](#), shows the register field descriptions for PACR E-P. All PACR registers are identical. They are divided into two sections because they occupy two non-contiguous address spaces.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

### 20.2.3 Peripheral Access Control Register (AIPSx\_PACRn)

This section describes PACR registers E-P, which control peripheral slots 32-127. See [Peripheral Access Control Register \(AIPS\\_PACRn\)](#) for the description of these registers.

Address: Base address + 40h offset + (4d × i), where i=0d to 11d

|       |    |     |     |     |    |     |     |     |    |     |     |     |    |     |     |     |

## 20.3 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

### 20.3.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

---

**functional description**

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

# Chapter 21

## Direct Memory Access Multiplexer (DMAMUX)

### 21.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

#### 21.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

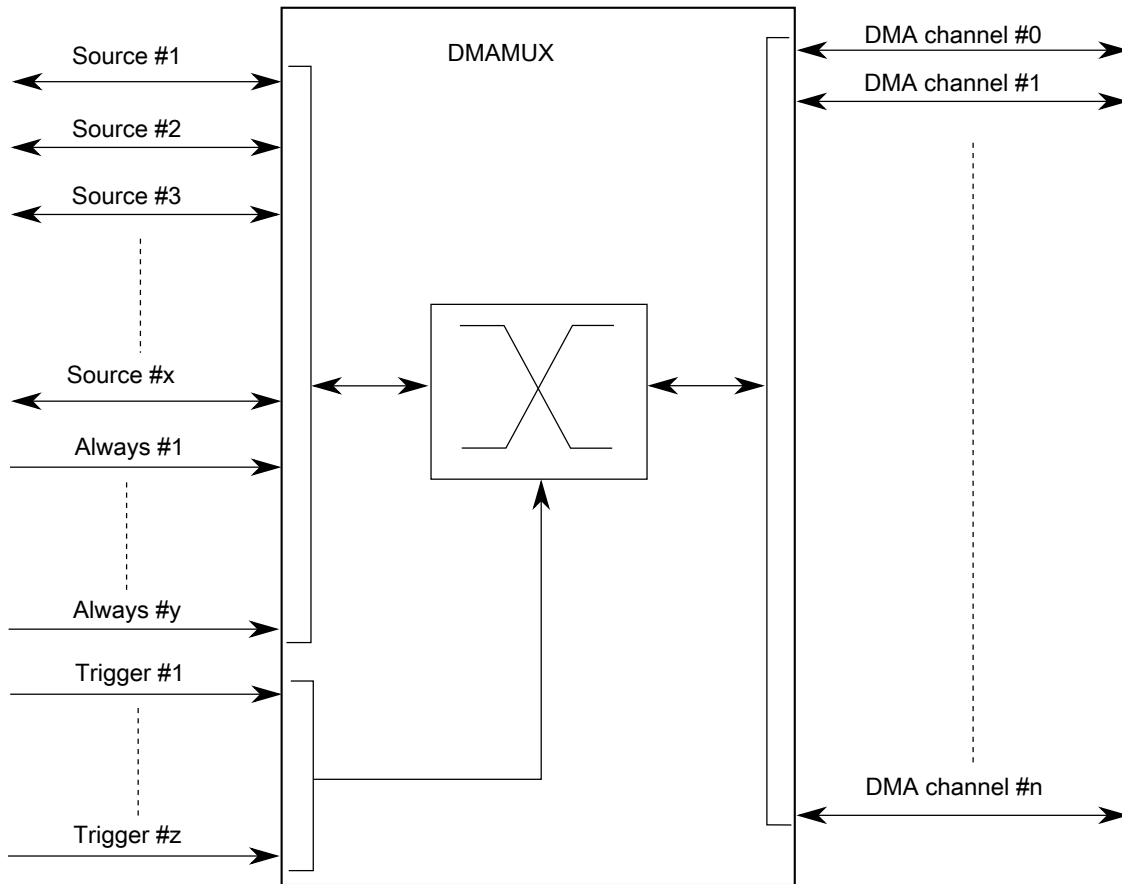

Figure 21-1. DMAMUX block diagram

## 21.1.2 Features

The DMAMUX module provides these features:

- Up to 52 peripheral slots and up to 10 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

## 21.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically. Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

## 21.2 External signal description

The DMAMUX has no external pins.

## 21.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

**DMAMUX memory map**

| Absolute address (hex) | Register name                                    | Width (in bits) | Access | Reset value | Section/page               |

#### 21.3.1 Channel Configuration register (DMAMUXx\_CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

#### NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: Base address + 0h offset + (1d × i), where i=0d to 15d

## 21.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

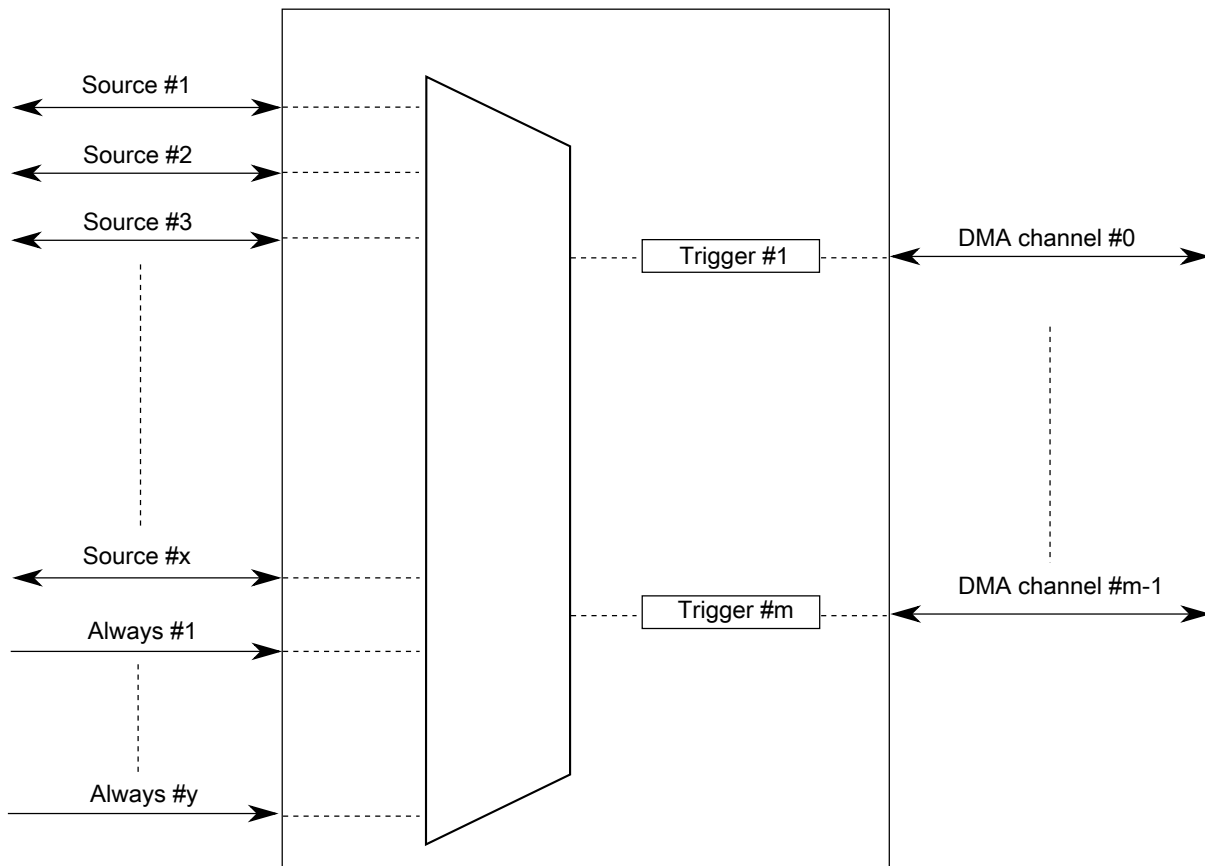

### 21.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention. The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

**Note**

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

**Figure 21-53. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 21-54. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 21-55. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

### 21.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

### 21.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 10 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

## 21.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 21.5.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 21.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
```

```
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8 (base address + 0x08).
3. Write 0x87 to CHCFG8 (base address + 0x08). (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
```

## Initialization/application information

```
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);

## Chapter 22

# Enhanced Direct Memory Access (eDMA)

### 22.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source- and destination-address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

#### 22.1.1 eDMA system block diagram

[Figure 22-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

**Figure 22-1. eDMA system block diagram**

### 22.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

**Table 22-1. eDMA engine submodules**

| Submodule                         | Function   |
|-----------------------------------|--|
| Address path                      | <p>This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI<sub>n</sub>[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.</p> <p>When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD<sub>n</sub>{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD<sub>n</sub>_CITER field, and a possible fetch of the next TCD<sub>n</sub> from memory as part of a scatter/gather operation.</p> |
| Data path                         | <p>This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).</p>   |
| Program model/channel arbitration | <p>This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).</p>  |
| Control                           | <p>This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.</p>  |

The transfer-control descriptor local memory is further partitioned into:

**Table 22-2. Transfer control descriptor memory**

| Submodule         | Description  |
|-------------------|--|
| Memory controller | <p>This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.</p> |
| Memory array      | <p>TCD storage for each channel's transfer profile.</p>  |

## 22.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
  - One interrupt per channel, optionally asserted at completion of major iteration count
  - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing
- Support for complex data structures

- Support to cancel transfers via software error detection and error correction
- Error detection and error correction

In the discussion of this module, *n* is used to reference the channel number.

## 22.2 Modes of operation

The eDMA operates in the following modes:

**Table 22-3. Modes of operation**

| Mode   | Description  |
|--------|--|
| Normal | In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.<br><br>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data. |
| Debug  | DMA operation is configurable in Debug mode via the control register: <ul style="list-style-type: none"> <li>• If CR[EDBG] is cleared, the DMA continues to operate.</li> <li>• If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.</li> </ul>   |
| Wait   | Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.   |

## 22.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

### 22.3.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD<sub>*n*</sub> definition is presented as 11 registers of 16 or 32 bits.

## 22.3.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

### 22.3.3 TCD structure

<sup>1</sup> The fields implemented in Word 2 depend on whether DMA\_CR[EMLM] is 0 or 1.

## 22.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

### DMA memory map

| Absolute address (hex) | Register name   | Width (in bits) | Access                | Reset value                 | Section/page                |
|------------------------|---|-----------------|-----------------------|-----------------------------|-----------------------------|
| 4000_8000              | Control Register (DMA_CR)                               | 32              | R/W                   | 0000_0400h                  | <a href="#">22.3.1/515</a>  |

#### 22.3.1 Control Register (DMA\_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

#### NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn\_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn\_SADDR) or destination address (TCDn\_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn\_SADDR), to the final destination address (TCDn\_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn\_SLAST and TCDn\_DLAST\_SGA) are used to compute the next TCDn\_SADDR and TCDn\_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn\_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn\_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: 4000\_8000h base + 0h offset = 4000\_8000h

**DMA\_CR field descriptions**

| Field             | Description  |
|-------------------|--|
| 31–18<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 17<br>CX          | Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.  |
| 16<br>ECX         | Error Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt. |
| 15–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 10<br>GRP1PRI     | Channel Group 1 Priority<br><br>Group 1 priority level when fixed priority group arbitration is enabled.   |
| 9<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 8<br>GRP0PRI      | Channel Group 0 Priority<br><br>Group 0 priority level when fixed priority group arbitration is enabled.   |
| 7<br>EMLM         | Enable Minor Loop Mapping<br><br>0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field.<br>1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.  |
| 6<br>CLM          | Continuous Link Mode<br><br><b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request. If the channel's NBYTES value is the same as either the source or destination size, do not use channel linking to itself. The same data transfer profile can be achieved by simply increasing the NBYTES value. A larger NBYTES value provides more efficient, faster processing.   |

### DMA\_CR field descriptions (continued)

| Field         | Description   |
|---------------|---|
|               | 0 A minor loop channel link made to itself goes through channel arbitration before being activated again.<br>1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop. |
| 5<br>HALT     | Halt DMA Operations<br>0 Normal operation<br>1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.   |
| 4<br>HOE      | Halt On Error<br>0 Normal operation<br>1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.  |
| 3<br>ERGA     | Enable Round Robin Group Arbitration<br>0 Fixed priority arbitration is used for selection among the groups.<br>1 Round robin arbitration is used for selection among the groups.   |
| 2<br>ERCA     | Enable Round Robin Channel Arbitration<br>0 Fixed priority arbitration is used for channel selection within each group.<br>1 Round robin arbitration is used for channel selection within each group.   |
| 1<br>EDBG     | Enable Debug<br>0 When in debug mode, the DMA continues to operate.<br>1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.  |
| 0<br>Reserved | This field is reserved.   |

### 22.3.2 Error Status Register (DMA\_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle

See the Error Reporting and Handling section for more details.

Address: 4000\_8000h base + 4h offset = 4000\_8004h

| 0<br>DBE | Destination Bus Error<br><br>0 No destination bus error<br>1 The last recorded error was a bus error on a destination write  |

### 22.3.3 Enable Request Register (DMA\_ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

Address: 4000\_8000h base + Ch offset = 4000\_800Ch

## 22.3.4 Enable Error Interrupt Register (DMA\_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel’s error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

Address: 4000\_8000h base + 14h offset = 4000\_8014h

**22.3.5 Clear Enable Error Interrupt Register (DMA\_CEEI)**

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 18h offset = 4000\_8018h

| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAEE | 0 |   |   | CEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_CEEI field descriptions**

|               | 0 Clear only the EEI bit specified in the CEEI field<br>1 Clear all bits in EEI |
| 5<br>Reserved | This field is reserved.   |
| 4-0<br>CEEI   | Clear Enable Error Interrupt<br><br>Clears the corresponding bit in EEI         |

### 22.3.6 Set Enable Error Interrupt Register (DMA\_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEI bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 19h offset = 4000\_8019h

| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |
| Write | NOP | SAEI | 0 |   |   | SEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

### DMA\_SEEI field descriptions

| Field         | Description   |
|---------------|---|
| 7<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                      |

### 22.3.7 Clear Enable Request Register (DMA\_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Ah offset = 4000\_801Ah

| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAER | 0 |   |   | CERQ |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

#### DMA\_CERQ field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register                 |
| 6<br>CAER     | Clear All Enable Requests<br>0 Clear only the ERQ bit specified in the CERQ field<br>1 Clear all bits in ERQ |
| 5<br>Reserved | This field is reserved.  |
| 4-0<br>CERQ   | Clear Enable Request<br>Clears the corresponding bit in ERQ.   |

## 22.3.8 Set Enable Request Register (DMA\_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Bh offset = 4000\_801Bh

|       |     |      |   |      |   |   |   |   |
|-------|-----|------|---|------|---|---|---|---|
| Bit   | 7   | 6    | 5 | 4    | 3 | 2 | 1 | 0 |
| Read  | 0   | 0    | 0 | 0    | 0 | 0 | 0 | 0 |
| Write | NOP | SAER | 0 | SERQ |   |   |   |   |
| Reset | 0   | 0    | 0 | 0    | 0 | 0 | 0 | 0 |

### DMA\_SERQ field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register           |
| 6<br>SAER     | Set All Enable Requests<br>0 Set only the ERQ bit specified in the SERQ field<br>1 Set all bits in ERQ |
| 5<br>Reserved | This field is reserved.  |
| 4-0<br>SERQ   | Set Enable Request<br>Sets the corresponding bit in ERQ.   |

### 22.3.9 Clear DONE Status Bit Register (DMA\_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Ch offset = 4000\_801Ch

| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |
| Write | NOP | CADN | 0 |   |   | CDNE |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

#### DMA\_CDNE field descriptions

| Field         | Description   |
|---------------|---|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register                                    |
| 6<br>CADN     | Clears All DONE Bits<br>0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field<br>1 Clears all bits in TCDn_CSR[DONE] |
| 5<br>Reserved | This field is reserved.   |
| 4-0<br>CDNE   | Clear DONE Bit<br>Clears the corresponding bit in TCDn_CSR[DONE]  |

### 22.3.10 Set START Bit Register (DMA\_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Dh offset = 4000\_801Dh

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |
| Write | NOP | SAST | 0 |   |   | SSRT |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

#### DMA\_SSRT field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register   |
| 6<br>SAST     | Set All START Bits (activates all channels)<br>0 Set only the TCDn_CSR[START] bit specified in the SSRT field<br>1 Set all bits in TCDn_CSR[START] |
| 5<br>Reserved | This field is reserved.  |
| 4-0<br>SSRT   | Set START Bit<br>Sets the corresponding bit in TCDn_CSR[START]   |

### 22.3.11 Clear Error Register (DMA\_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Eh offset = 4000\_801Eh

| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAEI | 0 |   |   | CERR |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

#### DMA\_CERR field descriptions

| Field         | Description   |
|---------------|---|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register                  |
| 6<br>CAEI     | Clear All Error Indicators<br>0 Clear only the ERR bit specified in the CERR field<br>1 Clear all bits in ERR |
| 5<br>Reserved | This field is reserved.   |
| 4-0<br>CERR   | Clear Error Indicator<br>Clears the corresponding bit in ERR  |

### 22.3.12 Clear Interrupt Request Register (DMA\_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

### 22.3.13 Interrupt Request Register (DMA\_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

#### 22.3.14 Error Register (DMA\_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEL. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

### 22.3.15 Hardware Request Status Register (DMA\_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA’s arbitration logic. This view into the hardware request signals may be used for debug purposes.

#### NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 4000\_8000h base + 34h offset = 4000\_8034h

**22.3.17 Channel n Priority Register (DMA\_DCHPRIn)**

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: 4000\_8000h base + 100h offset + (1d × i), where i=0d to 31d

\* Notes:

- GRPPRI field: See bit field description.
- CHPRI field: See bit field description.

### DMA\_DCHPRIn field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>ECP      | Enable Channel Preemption.<br><br>0 Channel n cannot be suspended by a higher priority channel's service request.<br>1 Channel n can be temporarily suspended by the service request of a higher priority channel.   |
| 6<br>DPA      | Disable Preempt Ability.<br><br>0 Channel n can suspend a lower priority channel.<br>1 Channel n cannot suspend any channel, regardless of channel priority.   |
| 5-4<br>GRPPRI | Channel n Current Group Priority<br><br>Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored.<br><br><b>NOTE:</b> Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111. |
| 3-0<br>CHPRI  | Channel n Arbitration Priority<br><br>Channel priority when fixed-priority arbitration is enabled<br><br><b>NOTE:</b> Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.  |

### 22.3.18 TCD Source Address (DMA\_TCDn\_SADDR)

Address: 4000\_8000h base + 1000h offset + (32d × i), where i=0d to 31d

\* Notes:

- x = Undefined at reset.

### DMA\_TCDn\_SADDR field descriptions

| Field         | Description   |
|---------------|---|
| 31-0<br>SADDR | Source Address<br><br>Memory address pointing to the source data. |

### 22.3.19 TCD Signed Source Address Offset (DMA\_TCDn\_SOFF)

Address: 4000\_8000h base + 1004h offset + (32d × i), where i=0d to 31d

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

\* Notes:

- x = Undefined at reset.

#### DMA\_TCDn\_ATTR field descriptions

| Field         | Description   |
|---------------|---|
| 15–11<br>SMOD | Source Address Modulo<br><br>0 Source address modulo feature is disabled<br>≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. |
| 10–8<br>SSIZE | Source data transfer size<br><br><b>NOTE:</b> Using a Reserved value causes a configuration error.  |

*Table continues on the next page...*

### DMA\_TCDn\_ATTR field descriptions (continued)

| Field        | Description   |
|--------------|---|
|              | 000 8-bit<br>001 16-bit<br>010 32-bit<br>011 Reserved<br>100 16-byte burst<br>101 32-byte burst<br>110 Reserved<br>111 Reserved |
| 7-3<br>DMOD  | Destination Address Modulo<br><br>See the SMOD definition   |
| 2-0<br>DSIZE | Destination data transfer size<br><br>See the SSIZE definition  |

### 22.3.21 TCD Minor Byte Count (Minor Loop Disabled) (DMA\_TCDn\_NBYTES\_MLNO)

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 4000\_8000h base + 1008h offset + (32d × i), where i=0d to 31d

- \* Notes:
- x = Undefined at reset.

### DMA\_TCDn\_NBYTES\_MLNO field descriptions

| Field          | Description   |
|----------------|---|
| 31-0<br>NBYTES | Minor Byte Transfer Count<br><br>Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until |

**DMA\_TCDn\_NBYTES\_MLNO field descriptions (continued)**

| Field | Description  |
|-------|--|
|       | <p>the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.</p> <p><b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.</p> |

**22.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA\_TCDn\_NBYTES\_MLOFFNO)**

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: 4000\_8000h base + 1008h offset + (32d × i), where i=0d to 31d

|       |        |    |       |    |        |    |    |    |    |    |    |    |    |    |    |    |

| 29–0<br>NBYTES | <p>Minor Byte Transfer Count</p> <p>Number of bytes to be transferred in each service request of the channel.</p> <p>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.</p> |

### 22.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA\_TCDn\_NBYTES\_MLOFFYES)

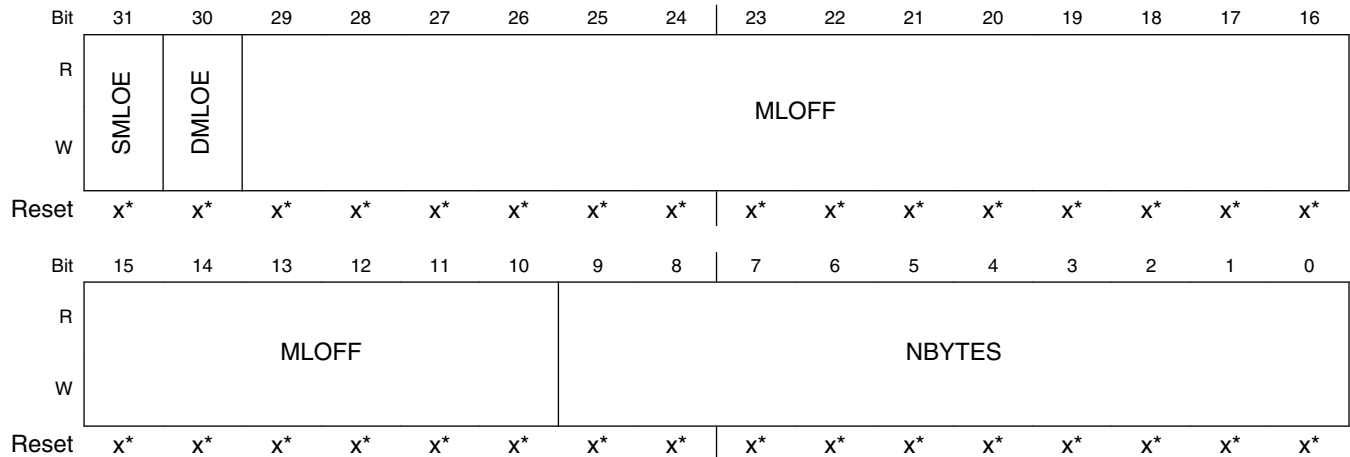

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: 4000\_8000h base + 1008h offset + (32d × i), where i=0d to 31d

\* Notes:

- x = Undefined at reset.

### DMA\_TCDn\_NBYTES\_MLOFFYES field descriptions

| Field          | Description  |
|----------------|--|
| 31<br>SMLOE    | Source Minor Loop Offset Enable<br>Selects whether the minor loop offset is applied to the source address upon minor loop completion.<br>0 The minor loop offset is not applied to the SADDR<br>1 The minor loop offset is applied to the SADDR  |
| 30<br>DMLOE    | Destination Minor Loop Offset enable<br>Selects whether the minor loop offset is applied to the destination address upon minor loop completion.<br>0 The minor loop offset is not applied to the DADDR<br>1 The minor loop offset is applied to the DADDR  |
| 29–10<br>MLOFF | If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.   |
| 9–0<br>NBYTES  | Minor Byte Transfer Count<br>Number of bytes to be transferred in each service request of the channel.<br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

## 22.3.24 TCD Last Source Address Adjustment (DMA\_TCDn\_SLAST)

Address: 4000\_8000h base + 100Ch offset + (32d × i), where i=0d to 31d

- \* Notes:
- x = Undefined at reset.

### DMA\_TCDn\_SLAST field descriptions

| Field         | Description   |
|---------------|---|
| 31–0<br>SLAST | <p>Last Source Address Adjustment</p> <p>Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure.</p> <p>This register uses two's complement notation; the overflow bit is discarded.</p> |

## 22.3.25 TCD Destination Address (DMA\_TCDn\_DADDR)

Address: 4000\_8000h base + 1010h offset + (32d × i), where i=0d to 31d

- \* Notes:
- x = Undefined at reset.

### DMA\_TCDn\_DADDR field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>DADDR | <p>Destination Address</p> <p>Memory address pointing to the destination data.</p> |

### 22.3.26 TCD Signed Destination Address Offset (DMA\_TCDn\_DOFF)

Address: 4000\_8000h base + 1014h offset + (32d × i), where i=0d to 31d

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | DOFF |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Write |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | x*   | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

#### DMA\_TCDn\_DOFF field descriptions

| Field        | Description   |
|--------------|---|
| 15–0<br>DOFF | Destination Address Signed Offset<br><br>Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed. |

### 22.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA\_TCDn\_CITER\_ELINKYES)

If TCDn\_CITER[ELINK] is set, the TCDn\_CITER register is defined as follows.

Address: 4000\_8000h base + 1016h offset + (32d × i), where i=0d to 31d

|       |       |    |    |    |        |    |    |    |       |
|-------|-------|----|----|----|--------|----|----|----|-------|
| Bit   | 15    | 14 | 13 | 12 | 11     | 10 | 9  | 8  |       |
| Read  | ELINK |    | 0  |    | LINKCH |    |    |    | CITER |
| Write |       |    |    |    |        |    |    |    |       |
| Reset | x*    | x* | x* | x* | x*     | x* | x* | x* |       |
| Bit   | 7     | 6  | 5  | 4  | 3      | 2  | 1  | 0  |       |
| Read  | CITER |    |    |    |        |    |    |    |       |
| Write |       |    |    |    |        |    |    |    |       |
| Reset | x*    | x* | x* | x* | x*     | x* | x* | x* |       |

\* Notes:

- x = Undefined at reset.

#### DMA\_TCDn\_CITER\_ELINKYES field descriptions

| Field       | Description   |
|-------------|---|
| 15<br>ELINK | Enable channel-to-channel linking on minor-loop complete<br><br>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. |

Table continues on the next page...

### DMA\_TCDn\_CITER\_ELINKYES field descriptions (continued)

| Field          | Description   |
|----------------|---|
|                | <p>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.</p> <p>0 The channel-to-channel linking is disabled<br/>1 The channel-to-channel linking is enabled</p>  |
| 14<br>Reserved | This field is reserved.   |
| 13–9<br>LINKCH | <p>Link Channel Number</p> <p>If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.</p>   |
| 8–0<br>CITER   | <p>Current Major Iteration Count</p> <p>This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.</p> <p><b>NOTE:</b> When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</p> <p><b>NOTE:</b> If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</p> |

### 22.3.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA\_TCDn\_CITER\_ELINKNO)

If TCDn\_CITER[ELINK] is cleared, the TCDn\_CITER register is defined as follows.

Address: 4000\_8000h base + 1016h offset + (32d × i), where i=0d to 31d

|       |       |    |    |    |       |    |    |    |
|-------|-------|----|----|----|-------|----|----|----|
| Bit   | 15    | 14 | 13 | 12 | 11    | 10 | 9  | 8  |
| Read  | ELINK |    |    |    | CITER |    |    |    |
| Write | ELINK |    |    |    | CITER |    |    |    |
| Reset | x*    | x* | x* | x* | x*    | x* | x* | x* |
| Bit   | 7     | 6  | 5  | 4  | 3     | 2  | 1  | 0  |
| Read  | CITER |    |    |    |       |    |    |    |
| Write | CITER |    |    |    |       |    |    |    |
| Reset | x*    | x* | x* | x* | x*    | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### DMA\_TCDn\_CITER\_ELINKNO field descriptions

| Field         | Description   |
|---------------|---|
| 15<br>ELINK   | <p>Enable channel-to-channel linking on minor-loop complete</p> <p>As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.</p> <p>If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking.</p> <p><b>NOTE:</b> This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported.</p> <p>0 The channel-to-channel linking is disabled<br/>1 The channel-to-channel linking is enabled</p>   |
| 14–0<br>CITER | <p>Current Major Iteration Count</p> <p>This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.</p> <p><b>NOTE:</b> When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</p> <p><b>NOTE:</b> If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</p> |

### 22.3.29 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA\_TCDn\_DLASTSGA)

Address: 4000\_8000h base + 1018h offset + (32d × i), where i=0d to 31d

|       |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

## 22.4 Functional description

The operation of the eDMA is described in the following subsections.

### 22.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

**Figure 22-546. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $TCD_n\_CSR[START]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $TCD_n$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel  $x$  or  $y$  registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel  $x$  or  $y$  registers.

The following diagram illustrates the second part of the basic data flow:

**Figure 22-547. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

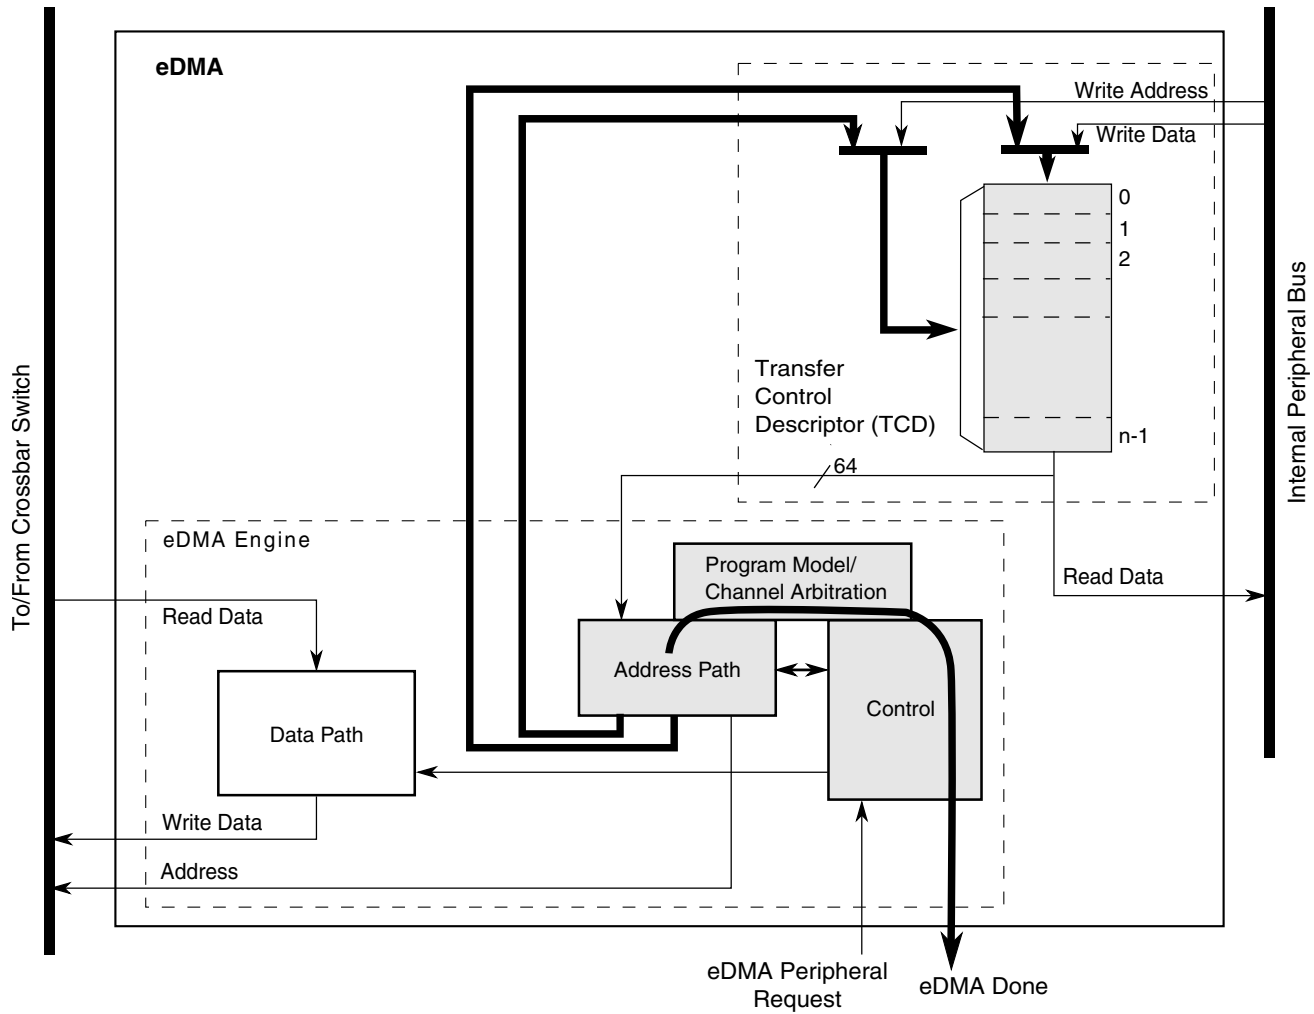

Figure 22-548. eDMA operation, part 3

### 22.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[E\_LINK] bit does not equal the TCDn\_BITER[E\_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error

occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

#### NOTE

The cancel transfer request allows the user to stop a large data transfer should the full data transfer no longer be needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 22.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

### 22.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

#### 22.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

**NOTE**

All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

**Table 22-549. eDMA peak transfer rates (Mbytes/sec)**

| System Speed, Width | Internal SRAM-to-Internal SRAM | 32 bit internal peripheral bus-to-Internal SRAM | Internal SRAM-to-32 bit internal peripheral bus |
|---------------------|--------------------------------|---|---|
| 66.7 MHz, 32 bit    | 133.3                          | 66.7  | 53.3  |
| 83.3 MHz, 32 bit    | 166.7                          | 83.3  | 66.7  |
| 100.0 MHz, 32 bit   | 200.0                          | 100.0   | 80.0  |
| 133.3 MHz, 32 bit   | 266.7                          | 133.3   | 106.7   |
| 150.0 MHz, 32 bit   | 300.0                          | 150.0   | 120.0   |

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

**22.4.4.2 Peak request rates**

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

**Table 22-550. Hardware service request process**

| Cycle   |  | Description  |
|---|--|--|
| With internal peripheral bus read and internal SRAM write | With SRAM read and internal peripheral bus write |  |
| 1   |  | eDMA peripheral request is asserted.   |
| 2   |  | The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD $n$ _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD $n$ word 7.                                   |
| 3   |  | Channel arbitration begins.  |
| 4   |  | Channel arbitration completes. The transfer control descriptor local memory read is initiated.   |
| 5–6   |  | The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles  |
| 7   |  | The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here. |
| 8–11  | 8–12   | The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.   |
| 12  | 13   | This cycle represents the data phase of the last destination write.  |
| 13  | 14   | The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD $n$ fields into the local memory. The TCD $n$ word 7 is read and checked for channel linking or scatter/gather requests.           |
| 14  | 15   | The appropriate fields in the first part of the TCD $n$ are written back into the local memory.  |
| 15  | 16   | The fields in the second part of the TCD $n$ are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.   |
| 16  | 17   | The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.  |

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles ( $4 + (4+5)/2 + 3$ ). This is the time from Cycle 4 to Cycle  $x + 5$ . The resulting peak request rate, as a function of the system frequency, is shown in the following table.

**Table 22-551. eDMA peak request rate (MReq/sec)**

| System frequency (MHz) | Request rate<br>with zero wait states | Request rate<br>with wait states |
|------------------------|---------------------------------------|----------------------------------|
| 66.6                   | 7.4                                   | 5.8                              |
| 83.3                   | 9.2                                   | 7.2                              |
| 100.0                  | 11.1                                  | 8.7                              |
| 133.3                  | 14.8                                  | 11.6                             |
| 150.0                  | 16.6                                  | 13.0                             |

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [ \text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit} ]$$

where:

**Table 22-552. Peak request formula operands**

| Operand  | Description   |
|----------|---|
| PEAKreq  | Peak request rate                                       |
| freq     | System frequency  |
| entry    | Channel startup (4 cycles)                              |
| read_ws  | Wait states seen during the system bus read data phase  |
| write_ws | Wait states seen during the system bus write data phase |
| exit     | Channel shutdown (3 cycles)                             |

### 22.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 1) + (1 + 3) + 3 ] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 2) + (1 + 1) + 3 ] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD $_n$ \_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

### Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

## 22.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 22.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI $_n$  registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.

5. Enable any hardware service requests via the ERQH and ERQL registers.
6. Request channel service via either:
  - Software: setting the TCD<sub>n</sub>\_CSR[START]
  - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD<sub>n</sub>\_SADDR, to the destination, as defined by TCD<sub>n</sub>\_DADDR, continue until the number of bytes specified by TCD<sub>n</sub>\_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD<sub>n</sub>\_SADDR, TCD<sub>n</sub>\_DADDR, and TCD<sub>n</sub>\_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 22-553. TCD Control and Status fields**

| TCD <sub>n</sub> _CSR field name | Description   |
|----------------------------------|---|
| START                            | Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware) |
| ACTIVE                           | Status bit indicating the channel is currently in execution   |
| DONE                             | Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)           |
| D_REQ                            | Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service          |
| BWC                              | Control bits for throttling bandwidth control of a channel  |
| E_SG                             | Control bit to enable scatter-gather feature  |
| INT_HALF                         | Control bit to enable interrupt when major loop is half complete  |
| INT_MAJ                          | Control bit to enable interrupt when major loop completes   |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

**Figure 22-549. Example of multiple loop iterations**

The following figure lists the memory array terms and how the TCD settings interrelate.

**Figure 22-550. Memory array terms**

## 22.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

### 22.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 22.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

### 22.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

## 22.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 22.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $TCDn\_CITER = TCDn\_BITER = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the  $TCDn\_CSR[DONE]$  bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```

TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
    
```

This generates the following event sequence:

1. User write to the TCDn\_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 1$  ( $TCDn\_BITER$ ).
7. The eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .
8. The channel retires and the eDMA goes idle or services the next channel.

### 22.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
4. eDMA engine reads: channel  $TCDn$  data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
  - a. Read byte from location  $0x1000$ , read byte from location  $0x1001$ , read byte from  $0x1002$ , read byte from  $0x1003$ .
  - b. Write 32-bits to location  $0x2000$  → first iteration of the minor loop.
  - c. Read byte from location  $0x1004$ , read byte from location  $0x1005$ , read byte from  $0x1006$ , read byte from  $0x1007$ .
  - d. Write 32-bits to location  $0x2004$  → second iteration of the minor loop.
  - e. Read byte from location  $0x1008$ , read byte from location  $0x1009$ , read byte from  $0x100A$ , read byte from  $0x100B$ .
  - f. Write 32-bits to location  $0x2008$  → third iteration of the minor loop.

- g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
- h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes:  $TCDn\_SADDR = 0x1010$ ,  $TCDn\_DADDR = 0x2010$ ,  $TCDn\_CITER = 1$ .
7. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ .
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 2$  ( $TCDn\_BITER$ ).
15. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

### 22.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2<sup>4</sup> byte (16-byte) size queue.

**Table 22-554. Modulo example**

| Transfer Number | Address    |
|-----------------|------------|
| 1               | 0x12345670 |
| 2               | 0x12345674 |
| 3               | 0x12345678 |
| 4               | 0x1234567C |
| 5               | 0x12345670 |
| 6               | 0x12345674 |

## 22.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

### 22.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD<sub>n</sub>\_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD<sub>n</sub>\_CSR[START] bit and the TCD<sub>n</sub>\_CSR[ACTIVE] bit. The minor-loop-

complete condition is indicated by both bits reading zero after the `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCDn_CSR bits |        |      | State  |
|-------|---------------|--------|------|--|
|       | START         | ACTIVE | DONE |  |
| 1     | 1             | 0      | 0    | Channel service request via software             |
| 2     | 0             | 1      | 0    | Channel is executing                             |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCDn_CSR bits |        |      | State  |
|-------|---------------|--------|------|--|
|       | START         | ACTIVE | DONE |  |
| 1     | 0             | 0      | 0    | Channel service request via hardware (peripheral request asserted) |
| 2     | 0             | 1      | 0    | Channel is executing   |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle                   |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle                   |

For both activation types, the major-loop-complete status is explicitly indicated via the `TCDn_CSR[DONE]` bit.

The `TCDn_CSR[START]` bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 22.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_NBYTES` values if read while a channel executes. The true values of the `SADDR`, `DADDR`, and `NBYTES` are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, `SADDR` and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 22.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The `TCDn_CSR[ACTIVE]` bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two `TCDn_CSR[ACTIVE]` bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

### 22.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[E_LINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set `TCD12_CSR[START]` bit

2. Minor loop done → set TCD12\_CSR[START] bit
3. Minor loop done → set TCD12\_CSR[START] bit
4. Minor loop done, major loop done → set TCD7\_CSR[START] bit

When minor loop linking is enabled ( $TCDn\_CITER[E\_LINK] = 1$ ), the  $TCDn\_CITER[CITER]$  field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled ( $TCDn\_CITER[E\_LINK] = 0$ ), the  $TCDn\_CITER[CITER]$  field uses a 15-bit vector to form the current iteration count. The bits associated with the  $TCDn\_CITER[LINKCH]$  field are concatenated onto the CITER value to increase the range of the CITER.

**Note**

The  $TCDn\_CITER[E\_LINK]$  bit and the  $TCDn\_BITER[E\_LINK]$  bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

**Table 22-555. Channel Linking Parameters**

| Desired Link Behavior     | TCD Control Field Name | Description  |
|---------------------------|------------------------|--|
| Link at end of Minor Loop | CITER[E_LINK]          | Enable channel-to-channel linking on minor loop completion (current iteration) |
|                           | CITER[LINKCH]          | Link channel number when linking at end of minor loop (current iteration)      |
| Link at end of Major Loop | CSR[MAJOR_E_LINK]      | Enable channel-to-channel linking on major loop completion                     |
|                           | CSR[MAJOR_LINKCH]      | Link channel number when linking at end of major loop                          |

## 22.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 22.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 22.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e\_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e\_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e\_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e\_link bit.
2. Read back the TCD.major.e\_link bit.
3. Test the TCD.major.e\_link request status:
  - If TCD.major.e\_link = 1, the dynamic link attempt was successful.
  - If TCD.major.e\_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e\_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

### 22.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e\_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e\_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e\_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e\_link and TCD.e\_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link or TCD.e\_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

#### 22.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e\_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast\_sga field with the scatter/gather address.
4. Write 1b to the TCD.e\_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e\_sg request status and TCD.major.linkch value:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e\_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e\_sg value cleared the e\_sg bit).

### 22.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast\_sga field as a TCD identification (ID).

1. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCD.dlast\_sga field with the scatter/gather address.
3. Write 1b to the TCD.e\_sg bit.
4. Read back the TCD.e\_sg bit.
5. Test the TCD.e\_sg request status:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b, read the 32 bit TCD dlast\_sga field.

If e\_sg = 0b and the dlast\_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If  $e\_sg = 0b$  and the  $dlast\_sga$  changed, the dynamic link attempt was successful (the new TCD's  $e\_sg$  value cleared the  $e\_sg$  bit).

## Chapter 23

# External Watchdog Monitor (EWM)

### 23.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the  $\overline{\text{RESET}}$  pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM if allowed to time-out, provides an independent  $\overline{\text{EWM\_out}}$  pin that when asserted resets or places an external circuit into a safe mode. The CPU resets the EWM counter that is logically ANDed with an external digital input pin. This pin allows an external circuit to influence the  $\overline{\text{reset\_out}}$  signal.

#### 23.1.1 Features

Features of EWM module include:

- Independent LPO clock source
- Programmable time-out period specified in terms of number of EWM LPO clock cycles.

- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of  $\overline{\text{EWM\_out}}$ .
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 15 ( $\text{EWM\_service\_time}$ ) peripheral bus clock cycles.
- One output port,  $\overline{\text{EWM\_out}}$ , when asserted is used to reset or place the external circuit into safe mode.
- One Input port,  $\text{EWM\_in}$ , allows an external circuit to control the  $\overline{\text{EWM\_out}}$  signal.

## 23.1.2 Modes of Operation

This section describes the module's operating modes.

### 23.1.2.1 Stop Mode

When the EWM is in stop mode, the CPU services to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU service mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first service command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 15 ( $\text{EWM\_service\_time}$ ) peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM service instructions.

### 23.1.2.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

### 23.1.2.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 23.1.3 Block Diagram

This figure shows the EWM block diagram.

<sup>1</sup> Compare High > Counter > Compare Low

Figure 23-1. EWM Block Diagram

## 23.2 EWM Signal Descriptions

The EWM has two external signals, as shown in the following table.

**Table 23-1. EWM Signal Descriptions**

| Signal  | Description  | I/O |
|---------|--|-----|
| EWM_in  | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low. | I   |
| EWM_out | EWM reset out signal   | O   |

## 23.3 Memory Map/Register Definition

This section contains the module memory map and registers.

### EWM memory map

| Absolute address (hex) | Register name                    | Width (in bits) | Access                | Reset value | Section/page               |
|------------------------|----------------------------------|-----------------|-----------------------|-------------|----------------------------|
| 4006_1000              | Control Register (EWM_CTRL)      | 8               | R/W                   | 00h         | <a href="#">23.3.1/596</a> |
| 4006_1001              | Service Register (EWM_SERV)      | 8               | W<br>(always reads 0) | 00h         | <a href="#">23.3.2/597</a> |
| 4006_1002              | Compare Low Register (EWM_CMPL)  | 8               | R/W                   | 00h         | <a href="#">23.3.3/597</a> |
| 4006_1003              | Compare High Register (EWM_CMPH) | 8               | R/W                   | FFh         | <a href="#">23.3.4/598</a> |

### 23.3.1 Control Register (EWM\_CTRL)

The CTRL register is cleared by any reset.

#### NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

Address: 4006\_1000h base + 0h offset = 4006\_1000h

| Bit   | 7 | 6 | 5 | 4 | 3     | 2    | 1     | 0     |
|-------|---|---|---|---|-------|------|-------|-------|
| Read  | 0 |   |   |   | INTEN | INEN | ASSIN | EWMEN |
| Write | 0 |   |   |   |       |      |       |       |
| Reset | 0 | 0 | 0 | 0 | 0     | 0    | 0     | 0     |

### EWM\_CTRL field descriptions

| Field           | Description   |
|-----------------|---|
| 7-4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3<br>INTEN      | Interrupt Enable.<br>This bit when set and <code>EWM_out</code> is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.  |
| 2<br>INEN       | Input Enable.<br>This bit when set, enables the <code>EWM_in</code> port.   |
| 1<br>ASSIN      | <code>EWM_in</code> 's Assertion State Select.<br>Default assert state of the <code>EWM_in</code> signal is logic zero. Setting <code>ASSIN</code> bit inverts the assert state to a logic one.   |
| 0<br>EWMEN      | EWM enable.<br>This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the <code>EWM_out</code> signal. Clearing <code>EWMEN</code> bit disables the EWM, and therefore it cannot be enabled until a reset occurs, due to the write-once nature of this bit. |

### 23.3.2 Service Register (EWM\_SERV)

The `SERV` register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

Address: `4006_1000h` base + `1h` offset = `4006_1001h`

### EWM\_SERV field descriptions

| Field          | Description   |
|----------------|---|
| 7-0<br>SERVICE | The EWM service mechanism requires the CPU to write two values to the <code>SERV</code> register: a first data byte of <code>0xB4</code> , followed by a second data byte of <code>0x2C</code> . The EWM service is illegal if either of the following conditions is true. <ul style="list-style-type: none"> <li>The first or second data byte is not written correctly.</li> <li>The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <code>EWM_service_time</code>.</li> </ul> |

### 23.3.3 Compare Low Register (EWM\_CMPL)

The `CMPL` register is reset to zero after a CPU reset. This provides no minimum time for the CPU to service the EWM counter.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

Address: 4006\_1000h base + 2h offset = 4006\_1002h

**EWM\_CMPLE field descriptions**

| Field           | Description   |
|-----------------|---|
| 7-0<br>COMPAREL | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum service time is required. |

**23.3.4 Compare High Register (EWM\_CMPH)**

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to service the EWM counter.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

**NOTE**

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Address: 4006\_1000h base + 3h offset = 4006\_1003h

**EWM\_CMPH field descriptions**

| Field           | Description   |
|-----------------|---|
| 7-0<br>COMPAREH | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum service time is required. |

## 23.4 Functional Description

The following sections describe functional details of the EWM module.

### 23.4.1 The $\overline{\text{EWM\_out}}$ Signal

The  $\overline{\text{EWM\_out}}$  is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the  $\overline{\text{EWM\_out}}$  could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The  $\overline{\text{EWM\_out}}$  signal remains deasserted when the EWM is being regularly serviced by the CPU within the programmable service window, indicating that the application code is executed as expected.

The  $\overline{\text{EWM\_out}}$  signal is asserted in any of the following conditions:

- Servicing the EWM when the counter value is less than CMPL value.
- If the EWM counter value reaches the CMPH value, and no EWM service has occurred.
- Servicing the EWM when the counter value is more than CMPL and less than CMPH values and EWM\_in signal is asserted.
- If functionality of EWM\_in pin is enabled and EWM\_in pin is asserted while servicing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the  $\overline{\text{EWM\_out}}$  pin)

On a normal reset, the  $\overline{\text{EWM\_out}}$  is asserted. To deassert the  $\overline{\text{EWM\_out}}$ , set EWMEN bit in the CTRL register to enable the EWM.

If the  $\overline{\text{EWM\_out}}$  signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. It takes the  $\overline{\text{EWM\_out}}$  output condition only after you enable the EWM by the EWMEN bit in the CTRL register.

When the  $\overline{\text{EWM\_out}}$  pin is asserted, it can only be deasserted by forcing a MCU reset.

#### Note

$\overline{\text{EWM\_out}}$  pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

## 23.4.2 The EWM\_in Signal

The EWM\_in is a digital input signal that allows an external circuit to control the EWM\_out signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with this circuit's behavior, it can then actively initiate the EWM\_out signal that controls the gating circuit.

The EWM\_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM\_in functionality (setting the CTRL[INEN] bit), the EWM\_in signal must be in the deasserted state prior to the CPU servicing the EWM. This ensures that the EWM\_out stays in the deasserted state; otherwise, the EWM\_out pin is asserted.

### Note

You must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore providing a reasonable time after a power-on reset for the external monitoring circuit to stabilize and ensure that the EWM\_in pin is deasserted.

## 23.4.3 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero, after a CPU reset, or a EWM refresh cycle. The counter value is not accessible to the CPU.

## 23.4.4 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a service window, which is used by the CPU to service/refresh the EWM module.

- If the CPU services the EWM when the counter value lies between CMPL value and CMPH value, the counter is reset to zero. This is a legal service operation.
- If the CPU executes a EWM service/refresh action outside the legal service window,  $\overline{\text{EWM\_out}}$  is asserted.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1),  $\overline{\text{EWM\_out}}$  is asserted.

### 23.4.5 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers. Therefore, three possible conditions can occur:

**Table 23-7. EWM Refresh Mechanisms**

| Condition   | Mechanism   |
|---|---|
| A unique EWM service occurs when $\text{CMPL} < \text{Counter} < \text{CMPH}$ . | The software behaves as expected and the counter of the EWM is reset to zero, and $\overline{\text{EWM\_out}}$ pin remains in the deasserted state.<br><b>Note:</b> $\overline{\text{EWM\_in}}$ pin is also assumed to be in the deasserted state.                                      |
| A unique EWM service occurs when $\text{Counter} < \text{CMPL}$                 | The software services the EWM and therefore resets the counter to zero and asserts the $\overline{\text{EWM\_out}}$ pin (irrespective of the $\overline{\text{EWM\_in}}$ pin). The $\overline{\text{EWM\_out}}$ pin is expected to gate critical safety circuits.                       |
| Counter value reaches CMPH prior to a unique EWM service                        | The counter value reaches the CMPH value and no service of the EWM resets the counter to zero and assert the $\overline{\text{EWM\_out}}$ pin (irrespective of the $\overline{\text{EWM\_in}}$ pin). The $\overline{\text{EWM\_out}}$ pin is expected to gate critical safety circuits. |

Any illegal service on EWM has no effect on  $\overline{\text{EWM\_out}}$ .

### 23.4.6 EWM Interrupt

When  $\overline{\text{EWM\_out}}$  is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect  $\overline{\text{EWM\_out}}$ . The  $\overline{\text{EWM\_out}}$  signal can be deasserted only by forcing a system reset.

# Chapter 24

## Watchdog Timer (WDOG)

### 24.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Watchdog Timer (WDOG) keeps a watch on the system functioning and resets it in case of its failure. Reasons for failure include run-away software code and the stoppage of the system clock that in a safety critical system can lead to serious consequences. In such cases, the watchdog brings the system into a safe state of operation. The watchdog monitors the operation of the system by expecting periodic communication from the software, generally known as servicing or refreshing the watchdog. If this periodic refreshing does not occur, the watchdog resets the system.

### 24.2 Features

The features of the Watchdog Timer (WDOG) include:

- Clock source input independent from CPU/bus clock. Choice between two clock sources:
  - Low-power oscillator (LPO)
  - External system clock
- Unlock sequence for allowing updates to write-once WDOG control/configuration bits.
- All WDOG control/configuration bits are writable once only within 256 bus clock cycles of being unlocked.

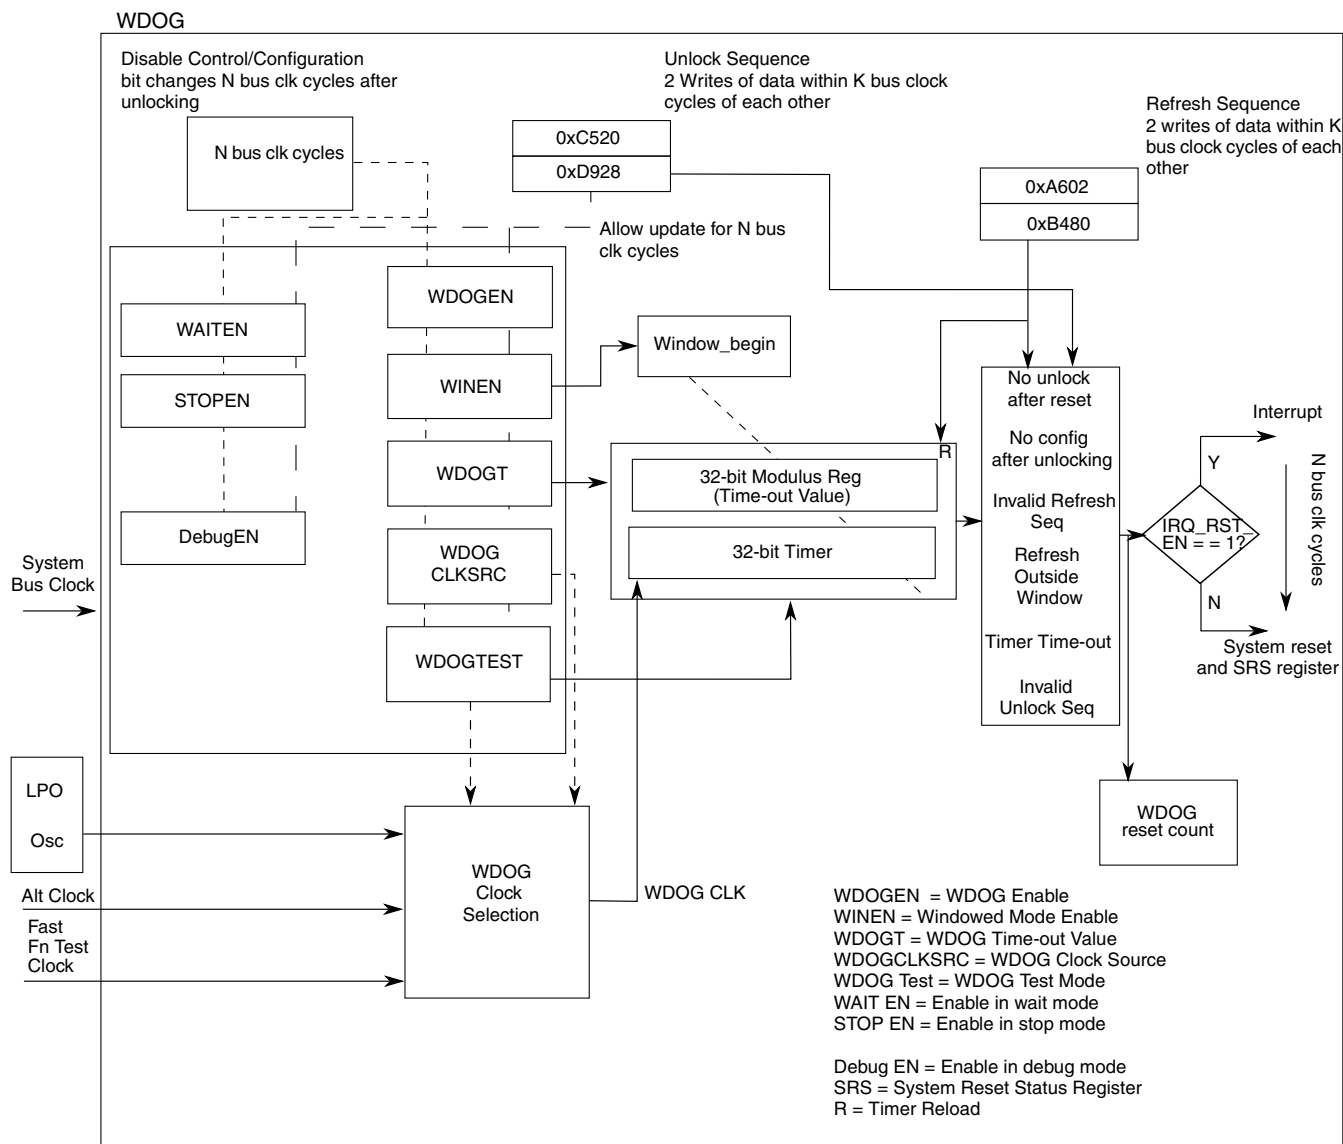

- You need to always update these bits after unlocking within 256 bus clock cycles. Failure to update these bits resets the system.
- Programmable time-out period specified in terms of number of WDOG clock cycles.
- Ability to test WDOG timer and reset with a flag indicating watchdog test.
  - Quick test—Small time-out value programmed for quick test.
  - Byte test—Individual bytes of timer tested one at a time.
  - Read-only access to the WDOG timer—Allows dynamic check that WDOG timer is operational.

**NOTE**

Reading the watchdog timer counter while running the watchdog on the bus clock might not give the accurate counter value.

- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to reset.
- Robust refresh mechanism
  - Write values of 0xA602 and 0xB480 to WDOG Refresh Register within 20 bus clock cycles.
- Count of WDOG resets as they occur.
- Configurable interrupt on time-out to provide debug breadcrumbs. This is followed by a reset after 256 bus clock cycles.

## 24.3 Functional overview

**Figure 24-1. WDOG operation**

The preceding figure shows the operation of the watchdog. The values for N and K are:

- N = 256
- K = 20

The watchdog is a fail safe mechanism that brings the system into a known initial state in case of its failure due to CPU clock stopping or a run-away condition in code execution. In its simplest form, the watchdog timer runs continuously off a clock source and expects

to be serviced periodically, failing which it resets the system. This ensures that the software is executing correctly and has not run away in an unintended direction. Software can adjust the period of servicing or the time-out value for the watchdog timer to meet the needs of the application.

You can select a windowed mode of operation that expects the servicing to be done only in a particular window of the time-out period. An attempted servicing of the watchdog outside this window results in a reset. By operating in this mode, you can get an indication of whether the code is running faster than expected. The window length is also user programmable.

If a system fails to update/refresh the watchdog due to an unknown and persistent cause, it will be caught in an endless cycle of resets from the watchdog. To analyze the cause of such conditions, you can program the watchdog to first issue an interrupt, followed by a reset. In the interrupt service routine, the software can analyze the system stack to aid debugging.

To enhance the independence of watchdog from the system, it runs off an independent LPO oscillator clock. You can also switch over to an alternate clock source if required, through a control register bit.

### 24.3.1 Unlocking and updating the watchdog

As long as `ALLOW_UPDATE` in the watchdog control register is set, you can unlock and modify the write-once-only control and configuration registers:

1. Write `0xC520` followed by `0xD928` within 20 bus clock cycles to a specific unlock register (`WDOG_UNLOCK`).
2. Wait one bus clock cycle. You cannot update registers on the bus clock cycle immediately following the write of the unlock sequence.
3. An update window equal in length to the watchdog configuration time (`WCT`) opens. Within this window, you can update the configuration and control register bits.

These register bits can be modified only once after unlocking.

If none of the configuration and control registers is updated within the update window, the watchdog issues a reset, that is, interrupt-then-reset, to the system. Trying to unlock the watchdog within the `WCT` after an initial unlock has no effect. During the update operation, the watchdog timer is not paused and continues running in the background. After the update window closes, the watchdog timer restarts and the watchdog functions according to the new configuration.

The update feature is useful for applications that have an initial, non-safety critical part, where the watchdog is kept disabled or with a conveniently long time-out period. This means the application coder does not have to frequently service the watchdog. After the critical part of the application begins, the watchdog can be reconfigured as needed.

The watchdog issues a reset, that is, interrupt-then-reset if enabled, to the system for any of these invalid unlock sequences:

- Write any value other than 0xC520 or 0xD928 to the unlock register.
- ALLOW\_UPDATE is set and a gap of more than 20 bus clock cycles is inserted between the writing of the unlock sequence values.

An attempted refresh operation between the two writes of the unlock sequence and in the WCT time following a successful unlock, goes undetected. Also, see [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the unlock register.

### Note

A context switch during unlocking and refreshing may lead to a watchdog reset.

## 24.3.2 Watchdog configuration time (WCT)

To prevent unintended modification of the watchdog's control and configuration register bits, you are allowed to update them only within a period of 256 bus clock cycles after unlocking. This period is known as the watchdog configuration time (WCT). In addition, these register bits can be modified only once after unlocking them for editing, even after reset.

You must unlock the registers within WCT after system reset, failing which the WDOG issues a reset to the system. In other words, you must write at least the first word of the unlocking sequence within the WCT after reset. After this is done, you have a further 20 bus clock cycles, the maximum allowed gap between the words of the unlock sequence, to complete the unlocking operation. Thereafter, to make sure that you do not forget to configure the watchdog, the watchdog issues a reset if none of the WDOG control and configuration registers is updated in the WCT after unlock. After the close of this window or after the first write, these register bits are locked out from any further changes.

The watchdog timer keeps running according to its default configuration through unlocking and update operations that can extend up to a maximum total of  $2 \times \text{WCT} + 20$  bus clock cycles. Therefore, it must be ensured that the time-out value for the watchdog is always greater than  $2 \times \text{WCT} + 20$  bus clock cycles.

Updates in the write-once registers take effect only after the WCT window closes with the following exceptions for which changes take effect immediately:

- Stop, Wait, and Debug mode enable
- IRQ\_RST\_EN

The operations of refreshing the watchdog goes undetected during the WCT.

### 24.3.3 Refreshing the watchdog

A robust refreshing mechanism has been chosen for the watchdog. A valid refresh is a write of 0xA602 followed by 0xB480 within 20 bus clock cycles to watchdog refresh register. If these two values are written more than 20 bus cycles apart or if something other than these two values is written to the register, a watchdog reset, or interrupt-then-reset if enabled, is issued to the system. A valid refresh makes the watchdog timer restart on the next bus clock. Also, an attempted unlock operation in between the two writes of the refresh sequence goes undetected. See [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the refresh register.

### 24.3.4 Windowed mode of operation

In this mode of operation, a restriction is placed on the point in time within the time-out period at which the watchdog can be refreshed. The refresh is considered valid only when the watchdog timer increments beyond a certain count as specified by the watchdog window register. This is known as refreshing the watchdog within a window of the total time-out period. If a refresh is attempted before the timer reaches the window value, the watchdog generates a reset, or interrupt-then-reset if enabled. If there is no refresh at all, the watchdog times out and generates a reset or interrupt-then-reset if enabled.

### 24.3.5 Watchdog disabled mode of operation

When the watchdog is disabled through the WDOG\_EN bit in the watchdog status and control register, the watchdog timer is reset to zero and is disabled from counting until you enable it or it is enabled again by the system reset. In this mode, the watchdog timer cannot be refreshed—there is no requirement to do so while the timer is disabled. However, the watchdog still generates a reset, or interrupt-then-reset if enabled, on a non-

time-out exception. See [Generated Resets and Interrupts](#). You need to unlock the watchdog before enabling it. A system reset brings the watchdog out of the disabled mode.

### 24.3.6 Low-power modes of operation

The low-power modes of operation of the watchdog are described in the following table:

**Table 24-1. Low-power modes of operation**

| Mode       | Behavior   |
|------------|--|
| Wait       | If the WDOG is enabled (WAIT_EN = 1), it can run on bus clock or low-power oscillator clock (CLK_SRC = x) to generate interrupt (IRQ_RST_EN=1) followed by a reset on time-out. After reset the WDOG reset counter increments by one.  |
| Stop       | Where the bus clock is gated, the WDOG can run only on low-power oscillator clock (CLK_SRC=0) if it is enabled in stop (STOP_EN=1). In this case, the WDOG runs to time-out twice, and then generates a reset from its backup circuitry. Therefore, if you program the watchdog to time-out after 100 ms and then enter such a stop mode, the reset will occur after 200 ms. Also, in this case, no interrupt will be generated irrespective of the value of IRQ_RST_EN bit. After WDOG reset, the WDOG reset counter will also not increment. |
| Power-Down | The watchdog is <ul style="list-style-type: none"> <li>• static in LLS mode</li> <li>• powered off in VLLSx mode</li> </ul>  |

### 24.3.7 Debug modes of operation

You can program the watchdog to disable in debug modes through DBG\_EN in the watchdog control register. This results in the watchdog timer pausing for the duration of the mode. Register read/writes are still allowed, which means that operations like refresh, unlock, and so on are allowed. Upon exit from the mode, the timer resumes its operation from the point of pausing.

The entry of the system into the debug mode does not excuse it from compulsorily configuring the watchdog in the WCT time after unlock, unless the system bus clock is gated off, in which case the internal state machine pauses too. Failing to do so still results in a reset, or interrupt-then-reset, if enabled, to the system. Also, all of the exception conditions that result in a reset to the system, as described in [Generated Resets and Interrupts](#), are still valid in this mode. So, if an exception condition occurs and the system bus clock is on, a reset occurs, or interrupt-then-reset, if enabled.

The entry into Debug mode within WCT after reset is treated differently. The WDOG timer is kept reset to zero and there is no need to unlock and configure it within WCT. You must not try to refresh or unlock the WDOG in this state or unknown behavior may result. Upon exit from this mode, the WDOG timer restarts and the WDOG has to be unlocked and configured within WCT.

## 24.4 Testing the watchdog

For IEC 60730 and other safety standards, the expectation is that anything that monitors a safety function must be tested, and this test is required to be fault tolerant. To test the watchdog, its main timer and its associated compare and reset logic must be tested. To this end, two tests are implemented for the watchdog, as described in [Quick Test](#) and [Byte Test](#). A control bit is provided to put the watchdog into functional test mode. There is also an overriding test-disable control bit which allows the functional test mode to be disabled permanently. After it is set, this test-disable bit can only be cleared by a reset.

These two tests achieve the overall aim of testing the counter functioning and the compare and reset logic.

### Note

Do not enable the watchdog interrupt during these tests. If required, you must ensure that the effective time-out value is greater than WCT time. See [Generated Resets and Interrupts](#) for more details.

To run a particular test:

1. Select either quick test or byte test..
2. Set a certain test mode bit to put the watchdog in the functional test mode. Setting this bit automatically switches the watchdog timer to a fast clock source. The switching of the clock source is done to achieve a faster time-out and hence a faster test.

In a successful test, the timer times out after reaching the programmed time-out value and generates a system reset.

### Note

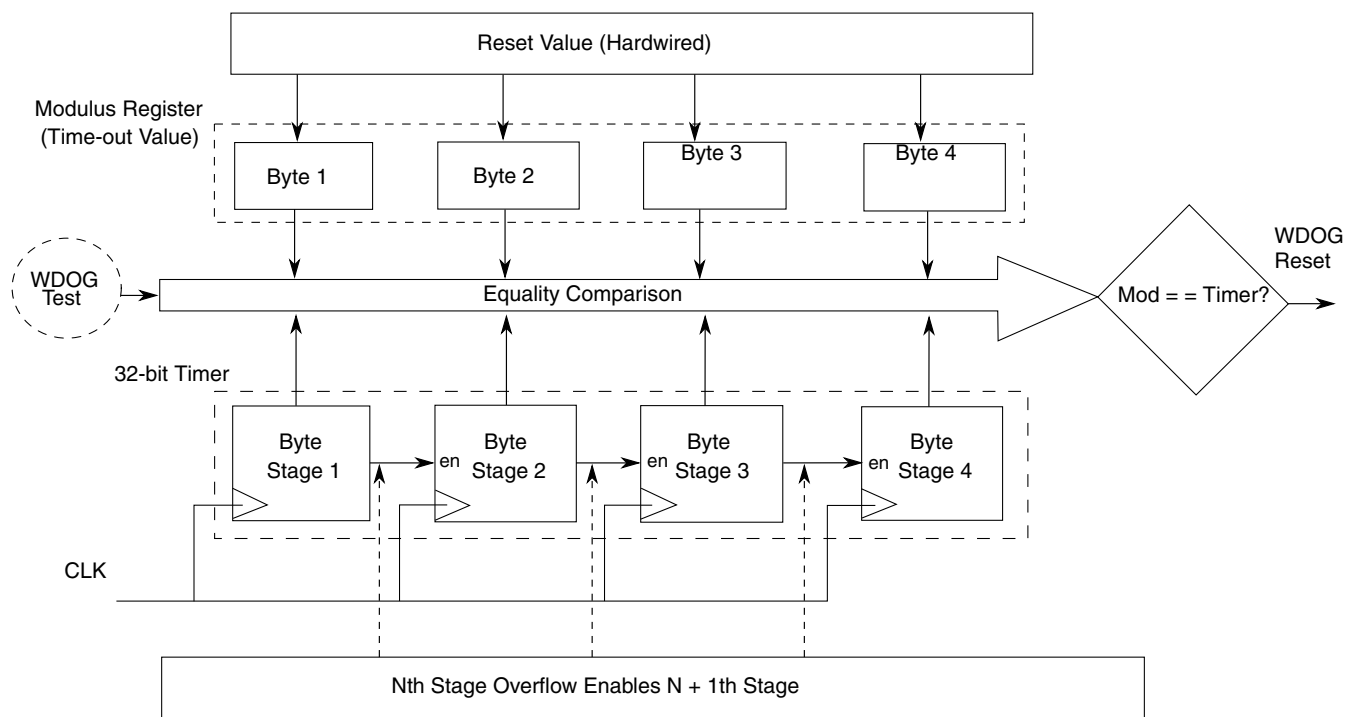

After emerging from a reset due to a watchdog test, unlock and configure the watchdog. The refresh and unlock operations and interrupt are not automatically disabled in the test mode.

## 24.4.1 Quick test

In this test, the time-out value of watchdog timer is programmed to a very low value to achieve quick time-out. The only difference between the quick test and the normal mode of the watchdog is that TESTWDOG is set for the quick test. This allows for a faster test of the watchdog reset mechanism.

## 24.4.2 Byte test

The byte test is a more thorough a test of the watchdog timer. In this test, the timer is split up into its constituent byte-wide stages that are run independently and tested for time-out against the corresponding byte of the time-out value register. The following figure explains the splitting concept:

**Figure 24-2. Watchdog timer byte splitting**

Each stage is an 8-bit synchronous counter followed by combinational logic that generates an overflow signal. The overflow signal acts as an enable to the  $N + 1$ th stage.

In the test mode, when an individual byte,  $N$ , is tested, byte  $N - 1$  is loaded forcefully with  $0xFF$ , and both these bytes are allowed to run off the clock source. By doing so, the overflow signal from stage  $N - 1$  is generated immediately, enabling counter stage  $N$ . The  $N$ th stage runs and compares with the  $N$ th byte of the time-out value register. In this

way, the byte N is also tested along with the link between it and the preceding stage. No other stages,  $N - 2$ ,  $N - 3...$  and  $N + 1$ ,  $N + 2...$  are enabled for the test on byte N. These disabled stages, except the most significant stage of the counter, are loaded with a value of 0xFF.

## 24.5 Backup reset generator

The backup reset generator generates the final reset which goes out to the system. It has a backup mechanism which ensures that in case the bus clock stops and prevents the main state machine from generating a reset exception/interrupt, the watchdog timer's time-out is separately routed out as a reset to the system. Two successive timer time-outs without an intervening system reset result in the backup reset generator routing out the time-out signal as a reset to the system.

## 24.6 Generated resets and interrupts

The watchdog generates a reset in the following events, also referred to as exceptions:

- A watchdog time-out
- Failure to unlock the watchdog within WCT time after system reset deassertion
- No update of the control and configuration registers within the WCT window after unlocking. At least one of the following registers must be written to within the WCT window to avoid reset:
  - WDOG\_ST\_CTRL\_H, WDOG\_ST\_CTRL\_L
  - WDOG\_TO\_VAL\_H, WDOG\_TO\_VAL\_L
  - WDOG\_WIN\_H, WDOG\_WIN\_L
  - WDOG\_PRESCALER
- A value other than the unlock sequence or the refresh sequence is written to the unlock and/or refresh registers, respectively.
- A gap of more than 20 bus cycles exists between the writes of two values of the unlock sequence.
- A gap of more than 20 bus cycles exists between the writes of two values of the refresh sequence.

The watchdog can also generate an interrupt. If `IRQ_RST_EN` is set, then on the above mentioned events `WDOG_ST_CTRL_L[INT_FLG]` is set, generating an interrupt. A watchdog reset is also generated WCT time later to ensure the watchdog is fault tolerant. The interrupt can be cleared by writing 1 to `INT_FLG`.

The gap of WCT between interrupt and reset means that the WDOG time-out value must be greater than WCT. Otherwise, if the interrupt was generated due to a time-out, a second consecutive time-out will occur in that WCT gap. This will trigger the backup reset generator to generate a reset to the system, prematurely ending the interrupt service routine execution. Also, jobs such as counting the number of watchdog resets would not be done.

## 24.7 Memory map and register definition

This section consists of the memory map and register descriptions.

### WDOG memory map

| Absolute address (hex) | Register name  | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|--|-----------------|--------|-------------|-----------------------------|
| 4005_2000              | Watchdog Status and Control Register High (WDOG_STCTRLH) | 16              | R/W    | 01D3h       | <a href="#">24.7.1/614</a>  |
| 4005_2002              | Watchdog Status and Control Register Low (WDOG_STCTRL)   | 16              | R/W    | 0001h       | <a href="#">24.7.2/615</a>  |
| 4005_2004              | Watchdog Time-out Value Register High (WDOG_TOVALH)      | 16              | R/W    | 004Ch       | <a href="#">24.7.3/616</a>  |
| 4005_2006              | Watchdog Time-out Value Register Low (WDOG_TOVAL)        | 16              | R/W    | 4B4Ch       | <a href="#">24.7.4/616</a>  |

Table continues on the next page...

**WDOG\_STCTRLH field descriptions (continued)**

| Field            | Description  |
|------------------|--|
|                  | 0 WDOG is disabled in CPU Stop mode.<br>1 WDOG is enabled in CPU Stop mode.  |
| 5<br>DBGEN       | Enables or disables WDOG in Debug mode.<br><br>0 WDOG is disabled in CPU Debug mode.<br>1 WDOG is enabled in CPU Debug mode.   |
| 4<br>ALLOWUPDATE | Enables updates to watchdog write-once registers, after the reset-triggered initial configuration window (WCT) closes, through unlock sequence.<br><br>0 No further updates allowed to WDOG write-once registers.<br>1 WDOG write-once registers can be unlocked for updating.   |
| 3<br>WINEN       | Enables Windowing mode.<br><br>0 Windowing mode is disabled.<br>1 Windowing mode is enabled.   |
| 2<br>IRQRSTEN    | Used to enable the debug breadcrumbs feature. A change in this bit is updated immediately, as opposed to updating after WCT.<br><br>0 WDOG time-out generates reset only.<br>1 WDOG time-out initially generates an interrupt. After WCT, it generates a reset.  |
| 1<br>CLKSRC      | Selects clock source for the WDOG timer and other internal timing operations.<br><br>0 WDOG clock sourced from LPO .<br>1 WDOG clock sourced from alternate clock source.  |
| 0<br>WDOGEN      | Enables or disables the WDOG's operation. In the disabled state, the watchdog timer is kept in the reset state, but the other exception conditions can still trigger a reset/interrupt. A change in the value of this bit must be held for more than one WDOG_CLK cycle for the WDOG to be enabled or disabled.<br><br>0 WDOG is disabled.<br>1 WDOG is enabled. |

**24.7.2 Watchdog Status and Control Register Low (WDOG\_STCTRL)**

Address: 4005\_2000h base + 2h offset = 4005\_2002h

|       |          |    |          |    |    |    |   |   |
|-------|----------|----|----------|----|----|----|---|---|
| Bit   | 15       | 14 | 13       | 12 | 11 | 10 | 9 | 8 |
| Read  | INTFLG   |    | Reserved |    |    |    |   |   |
| Write |          |    |          |    |    |    |   |   |
| Reset | 0        | 0  | 0        | 0  | 0  | 0  | 0 | 0 |
| Bit   | 7        | 6  | 5        | 4  | 3  | 2  | 1 | 0 |
| Read  | Reserved |    |          |    |    |    |   |   |
| Write |          |    |          |    |    |    |   |   |
| Reset | 0        | 0  | 0        | 0  | 0  | 0  | 0 | 1 |

### WDOG\_STCTRL field descriptions

| Field            | Description   |
|------------------|---|
| 15<br>INTFLG     | Interrupt flag. It is set when an exception occurs. IRQRSTEN = 1 is a precondition to set this flag. INTFLG = 1 results in an interrupt being issued followed by a reset, WCT later. The interrupt can be cleared by writing 1 to this bit. It also gets cleared on a system reset. |
| 14–0<br>Reserved | This field is reserved.<br><br><b>NOTE:</b> Do not modify this field value.   |

### 24.7.3 Watchdog Time-out Value Register High (WDOG\_TOVALH)

Address: 4005\_2000h base + 4h offset = 4005\_2004h

|       |           |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|-----------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TOVALHIGH |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write | TOVALHIGH |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0         | 0  | 0  | 0  | 0  | 0  | 0 | 0 |  | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |

#### WDOG\_TOVALH field descriptions

| Field             | Description  |
|-------------------|--|
| 15–0<br>TOVALHIGH | Defines the upper 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock. |

### 24.7.4 Watchdog Time-out Value Register Low (WDOG\_TOVALL)

The time-out value of the watchdog must be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.

Address: 4005\_2000h base + 6h offset = 4005\_2006h

|       |        |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|--------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TOVALL |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write | TOVALL |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0      | 1  | 0  | 0  | 1  | 0  | 1 | 1 |  | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |

#### WDOG\_TOVALL field descriptions

| Field          | Description  |
|----------------|--|
| 15–0<br>TOVALL | Defines the lower 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock. |

### 24.7.5 Watchdog Window Register High (WDOG\_WINH)

**NOTE**

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005\_2000h base + 8h offset = 4005\_2008h

|       |         |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|---------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15      | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WINHIGH |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write | WINHIGH |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0       | 0  | 0  | 0  | 0  | 0  | 0 | 0 |  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**WDOG\_WINH field descriptions**

| Field           | Description  |
|-----------------|--|
| 15–0<br>WINHIGH | Defines the upper 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the watchdog clock. In this mode, the watchdog can be refreshed only when the timer has reached a value greater than or equal to this window length. A refresh outside this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system. |

### 24.7.6 Watchdog Window Register Low (WDOG\_WINL)

**NOTE**

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005\_2000h base + Ah offset = 4005\_200Ah

|       |        |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|--------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WINLOW |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write | WINLOW |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0 | 0 |  | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

**WDOG\_WINL field descriptions**

| Field          | Description  |
|----------------|--|
| 15–0<br>WINLOW | Defines the lower 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the pre-scaled watchdog clock. In this mode, the watchdog can be refreshed only when the timer reaches a value greater than or equal to this window length value. A refresh outside of this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system. |

### 24.7.7 Watchdog Refresh register (WDOG\_REFRESH)

Address: 4005\_2000h base + Ch offset = 4005\_200Ch

|       |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WDOGREFRESH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write | WDOGREFRESH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 1           | 0  | 1  | 1  | 0  | 1  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### WDOG\_REFRESH field descriptions

| Field               | Description   |
|---------------------|---|
| 15–0<br>WDOGREFRESH | Watchdog refresh register. A sequence of 0xA602 followed by 0xB480 within 20 bus clock cycles written to this register refreshes the WDOG and prevents it from resetting the system. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system, or if IRQRSTEN is set, it interrupts and then resets the system. |

### 24.7.8 Watchdog Unlock register (WDOG\_UNLOCK)

Address: 4005\_2000h base + Eh offset = 4005\_200Eh

|       |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WDOGUNLOCK |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write | WDOGUNLOCK |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 1          | 1  | 0  | 1  | 1  | 0  | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 |

#### WDOG\_UNLOCK field descriptions

| Field              | Description  |
|--------------------|--|
| 15–0<br>WDOGUNLOCK | Writing the unlock sequence values to this register to makes the watchdog write-once registers writable again. The required unlock sequence is 0xC520 followed by 0xD928 within 20 bus clock cycles. A valid unlock sequence opens a window equal in length to the WCT within which you can update the registers. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system or if IRQRSTEN is set, it interrupts and then resets the system. The unlock sequence is effective only if ALLOWUPDATE is set. |

### 24.7.9 Watchdog Timer Output Register High (WDOG\_TMROUTH)

Address: 4005\_2000h base + 10h offset = 4005\_2010h

|       |              |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15           | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TIMEROUTHIGH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write | TIMEROUTHIGH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0            | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### WDOG\_TMROUTH field descriptions

| Field                | Description   |
|----------------------|---|
| 15–0<br>TIMEROUTHIGH | Shows the value of the upper 16 bits of the watchdog timer. |

### 24.7.10 Watchdog Timer Output Register Low (WDOG\_TMROUTL)

During Stop mode, the WDOG\_TIMER\_OUT will be caught at the pre-stop value of the watchdog timer. After exiting Stop mode, a maximum delay of 1 WDOG\_CLK cycle + 3 bus clock cycles will occur before the WDOG\_TIMER\_OUT starts following the watchdog timer.

Address: 4005\_2000h base + 12h offset = 4005\_2012h

|       |             |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|-------------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TIMEROUTLOW |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write |             |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0 | 0 |  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### WDOG\_TMROUTL field descriptions

| Field               | Description   |
|---------------------|---|
| 15–0<br>TIMEROUTLOW | Shows the value of the lower 16 bits of the watchdog timer. |

### 24.7.11 Watchdog Reset Count register (WDOG\_RSTCNT)

Address: 4005\_2000h base + 14h offset = 4005\_2014h

|       |        |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
|-------|--------|----|----|----|----|----|---|---|--|---|---|---|---|---|---|---|---|
| Bit   | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 |  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | RSTCNT |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Write |        |    |    |    |    |    |   |   |  |   |   |   |   |   |   |   |   |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0 | 0 |  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### WDOG\_RSTCNT field descriptions

| Field          | Description   |
|----------------|---|
| 15–0<br>RSTCNT | Counts the number of times the watchdog resets the system. This register is reset only on a POR. Writing 1 to the bit to be cleared enables you to clear the contents of this register. |

## 24.7.12 Watchdog Prescaler register (WDOG\_PRESC)

Address: 4005\_2000h base + 16h offset = 4005\_2016h

|       |          |    |    |    |    |          |   |   |   |   |   |   |   |   |   |   |
|-------|----------|----|----|----|----|----------|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15       | 14 | 13 | 12 | 11 | 10       | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | 0        |    |    |    |    | PRESCVAL |   |   | 0 |   |   |   |   |   |   |   |
| Write | [Shaded] |    |    |    |    |          |   |   |   |   |   |   |   |   |   |   |
| Reset | 0        | 0  | 0  | 0  | 0  | 1        | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### WDOG\_PRESC field descriptions

| Field             | Description  |
|-------------------|--|
| 15–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 10–8<br>PRESCVAL  | 3-bit prescaler for the watchdog clock source. A value of zero indicates no division of the input WDOG clock. The watchdog clock is divided by (PRESCVAL + 1) to provide the prescaled WDOG_CLK. |
| 7–0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

## 24.8 Watchdog operation with 8-bit access

### 24.8.1 General guideline

When performing 8-bit accesses to the watchdog's 16-bit registers where the intention is to access both the bytes of a register, place the two 8-bit accesses one after the other in your code.

### 24.8.2 Refresh and unlock operations with 8-bit access

One exception condition that generates a reset to the system is the write of any value other than those required for a legal refresh/update sequence to the respective refresh and unlock registers.

For an 8-bit access to these registers, writing a correct value requires at least two bus clock cycles, resulting in an invalid value in the registers for one cycle. Therefore, the system is reset even if the intention is to write a correct value to the refresh/unlock register. Keeping this in mind, the exception condition for 8-bit accesses is slightly modified.

Whereas the match for a correct value for a refresh/unlock sequence is as according to the original definition, the match for an incorrect value is done byte-wise on the refresh/unlock rather than for the whole 16-bit value. This means that if the high byte of the refresh/unlock register contains any value other than high bytes of the two values that make up the sequence, it is treated as an exception condition, leading to a reset or interrupt-then-reset. The same holds true for the lower byte of the refresh or unlock register. Take the refresh operation that expects a write of 0xA602 followed by 0xB480 to the refresh register, as an example.

**Table 24-15. Refresh for 8-bit access**

|                      | WDOG_REFRESH[15:8] | WDOG_REFRESH[7:0] | Sequence value1 or value2 match     | Mismatch exception |
|----------------------|--------------------|-------------------|-------------------------------------|--------------------|
| <b>Current Value</b> | 0xB4               | 0x80              | Value2 match                        | No                 |
| <b>Write 1</b>       | 0xB4               | 0x02              | No match                            | No                 |
| <b>Write 2</b>       | 0xA6               | 0x02              | Value1 match                        | No                 |
| <b>Write 3</b>       | 0xB4               | 0x02              | No match                            | No                 |
| <b>Write 4</b>       | 0xB4               | 0x80              | Value2 match.<br>Sequence complete. | No                 |
| <b>Write 5</b>       | 0x02               | 0x80              | No match                            | Yes                |

As shown in the preceding table, the refresh register holds its reset value initially. Thereafter, two 8-bit accesses are performed on the register to write the first value of the refresh sequence. No mismatch exception is registered on the intermediate write, Write1. The sequence is completed by performing two more 8-bit accesses, writing in the second value of the sequence for a successful refresh. It must be noted that the match of value2 takes place only when the complete 16-bit value is correctly written, write4. Hence, the requirement of writing value2 of the sequence within 20 bus clock cycles of value1 is checked by measuring the gap between write2 and write4.

It is reiterated that the condition for matching values 1 and 2 of the refresh or unlock sequence remains unchanged. The difference for 8-bit accesses is that the criterion for detecting a mismatch is less strict. Any 16-bit access still needs to adhere to the original guidelines, mentioned in the sections [Refreshing the Watchdog](#).

## 24.9 Restrictions on watchdog operation

This section mentions some exceptions to the watchdog operation that may not be apparent to you.

- Restriction on unlock/refresh operations—In the period between the closure of the WCT window after unlock and the actual reload of the watchdog timer, unlock and refresh operations need not be attempted.
- The update and reload of the watchdog timer happens two to three watchdog clocks after WCT window closes, following a successful configuration on unlock.
- Clock Switching Delay—The watchdog uses glitch-free multiplexers at two places – one to choose between the LPO oscillator input and alternate clock input, and the other to choose between the watchdog functional clock and fast clock input for watchdog functional test. A maximum time period of  $\sim 2$  clock A cycles plus  $\sim 2$  clock B cycles elapses from the time a switch is requested to the occurrence of the actual clock switch, where clock A and B are the two input clocks to the clock mux.
- For the windowed mode, there is a two to three bus clock latency between the watchdog counter going past the window value and the same registering in the bus clock domain.
- For proper operation of the watchdog, the watchdog clock must be at least five times slower than the system bus clock at all times. An exception is when the watchdog clock is synchronous to the bus clock wherein the watchdog clock can be as fast as the bus clock.
- WCT must be equivalent to at least three watchdog clock cycles. If not ensured, this means that even after the close of the WCT window, you have to wait for the synchronized system reset to deassert in the watchdog clock domain, before expecting the configuration updates to take effect.
- The time-out value of the watchdog should be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.
- You must take care not only to refresh the watchdog within the watchdog timer's actual time-out period, but also provide enough allowance for the time it takes for the refresh sequence to be detected by the watchdog timer, on the watchdog clock.
- Updates cannot be made in the bus clock cycle immediately following the write of the unlock sequence, but one bus clock cycle later.
- It should be ensured that the time-out value for the watchdog is always greater than  $2 \times \text{WCT time} + 20$  bus clock cycles.
- An attempted refresh operation, in between the two writes of the unlock sequence and in the WCT time following a successful unlock, will go undetected.

- Trying to unlock the watchdog within the WCT time after an initial unlock has no effect.
- The refresh and unlock operations and interrupt are not automatically disabled in the watchdog functional test mode.
- After emerging from a reset due to a watchdog functional test, you are still expected to go through the mandatory steps of unlocking and configuring the watchdog. The watchdog continues to be in its functional test mode and therefore you should pull the watchdog out of the functional test mode within WCT time of reset.
- After emerging from a reset due to a watchdog functional test, you still need to go through the mandatory steps of unlocking and configuring the watchdog.
- You must ensure that both the clock inputs to the glitchless clock multiplexers are alive during the switching of clocks. Failure to do so results in a loss of clock at their outputs.
- There is a gap of two to three watchdog clock cycles from the point that stop mode is entered to the watchdog timer actually pausing, due to synchronization. The same holds true for an exit from the stop mode, this time resulting in a two to three watchdog clock cycle delay in the timer restarting. In case the duration of the stop mode is less than one watchdog clock cycle, the watchdog timer is not guaranteed to pause.
- Consider the case when the first refresh value is written, following which the system enters stop mode with system bus clk still on. If the second refresh value is not written within 20 bus cycles of the first value, the system is reset, or interrupt-then-reset if enabled.

# Chapter 25

## Multipurpose Clock Generator (MCG)

### 25.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The multipurpose clock generator (MCG) module provides several clock source choices for the MCU.

The module contains a frequency-locked loop (FLL) and a phase-locked loop (PLL). The FLL is controllable by either an internal or an external reference clock. The PLL is controllable by the external reference clock. The module can select either an FLL or PLL output clock, or a reference clock (internal or external) as a source for the MCU system clock. The MCG operates in conjunction with a crystal oscillator, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock.

#### 25.1.1 Features

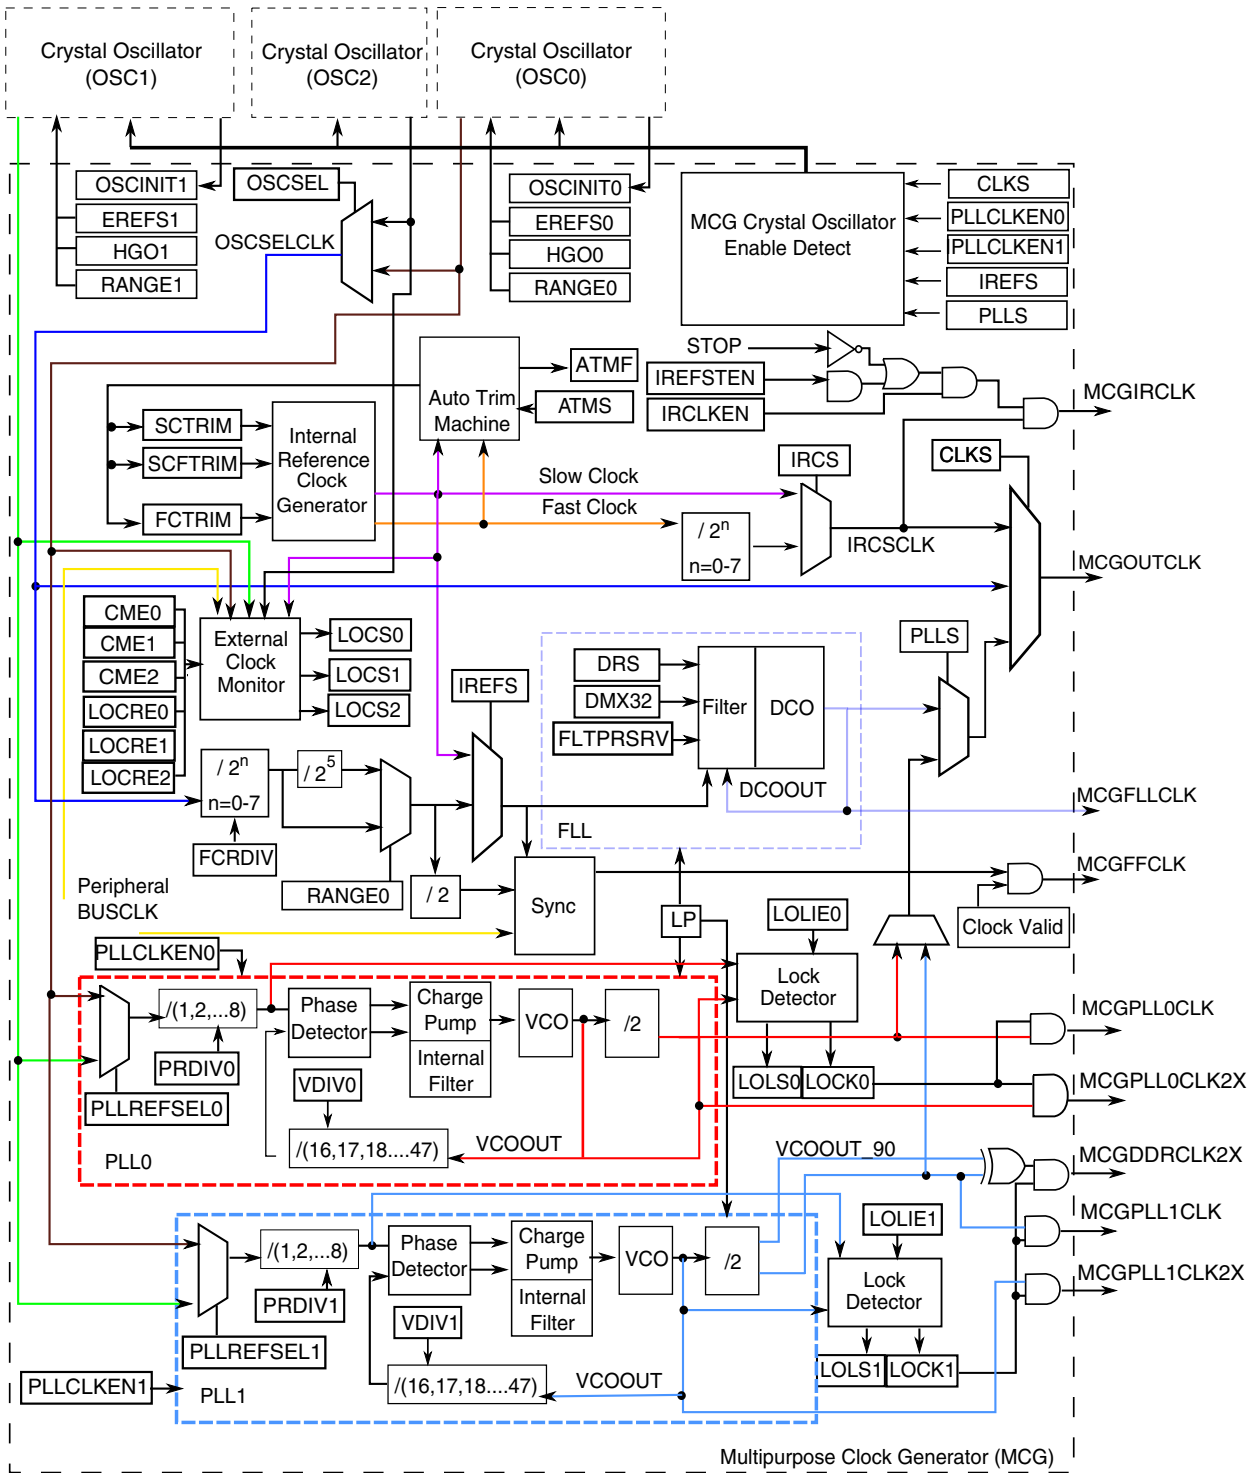

Key features of the MCG module are:

- Frequency-locked loop (FLL):
  - Digitally-controlled oscillator (DCO)
  - DCO frequency range is programmable for up to four different frequency ranges.
  - Option to program and maximize DCO output frequency for a low frequency external reference clock source.
  - Option to prevent FLL from resetting its current locked frequency when switching clock modes if FLL reference frequency is not changed.

- Internal or external reference clock can be used as the FLL source.
- Can be used as a clock source for other on-chip peripherals.
- Phase-locked loop (PLL):
  - Voltage-controlled oscillator (VCO)
  - Selectable External reference clock is used as the PLL source.
  - Modulo VCO frequency divider
  - Phase/Frequency detector
  - Integrated loop filter
  - Can be used as a clock source for other on-chip peripherals.
- Internal reference clock generator:
  - Slow clock with nine trim bits for accuracy
  - Fast clock with four trim bits
  - Can be used as source clock for the FLL. In FEI mode, only the slow Internal Reference Clock (IRC) can be used as the FLL source.
  - Either the slow or the fast clock can be selected as the clock source for the MCU.
  - Can be used as a clock source for other on-chip peripherals.
- Control signals for the MCG external reference low power oscillator clock generators are provided:
  - HGO0, RANGE0, EREFS0  
HGO1, RANGE1, EREFS1
- External clock from the Crystal Oscillator (OSC0):
  - Can be used as a source for the FLL and/or the PLL.
  - Can be selected as the clock source for the MCU.
- External clock from the Real Time Counter (RTC):
  - Can only be used as a source for the FLL.
  - Can be selected as the clock source for the MCU.
- External clock from the Crystal Oscillator (OSC1)
  - Can only be used as a source for the PLL.

- External clock monitor with reset and interrupt request capability to check for external clock failure when running in FBE, PEE, BLPE, or FEE modes
- Lock detector with interrupt request capability for use with the PLL
- Internal Reference Clocks Auto Trim Machine (ATM) capability using an external clock as a reference
- Reference dividers for both the FLL and the PLL are provided
- Reference dividers for the Fast Internal Reference Clock are provided
- MCG PLL0 Clock (MCGPLL0CLK) is provided as a clock source for other on-chip peripherals
- MCG PLL1 Clock (MCGPLL1CLK) is provided as a clock source for other on-chip peripherals
- MCG PLL0 2X Clock (MCGPLL0CLK2X) is provided as a clock source for other on-chip peripherals
- MCG PLL1 2X Clock (MCGPLL1CLK2X) is provided as a clock source for other on-chip peripherals
- MCG FLL Clock (MCGFLLCLK) is provided as a clock source for other on-chip peripherals
- MCG Fixed Frequency Clock (MCGFFCLK) is provided as a clock source for other on-chip peripherals
- MCG Internal Reference Clock (MCGIRCLK) is provided as a clock source for other on-chip peripherals

This figure presents the block diagram of the MCG module.

**Figure 25-1. Multipurpose Clock Generator (MCG) block diagram**

**NOTE**

Refer to the chip configuration chapter to identify the oscillator used in this MCU.

## 25.1.2 Modes of Operation

The MCG has the following modes of operation: FEI, FEE, FBI, FBE, PBE, PEE, BLPI, BLPE, and Stop. For details, see [MCG modes of operation](#).

## 25.2 External Signal Description

There are no MCG signals that connect off chip.

## 25.3 Memory Map/Register Definition

This section includes the memory map and register definition.

The MCG registers can only be written when in supervisor mode.

**MCG memory map**

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value                 | Section/page                |

### MCG\_C2 field descriptions (continued)

| Field       | Description   |
|-------------|---|
| 3<br>HGOO   | High Gain Oscillator Select<br>Controls the crystal oscillator mode of operation. See the Oscillator (OSC) chapter for more details.<br><br>0 Configure crystal oscillator for low-power operation.<br>1 Configure crystal oscillator for high-gain operation.  |
| 2<br>EREFS0 | External Reference Select<br>Selects the source for the external reference clock. See the Oscillator (OSC) chapter for more details.<br><br>0 External reference clock requested.<br>1 Oscillator requested.  |
| 1<br>LP     | Low Power Select<br>Controls whether the FLL or PLL is disabled in BLPI and BLPE modes. In FBE or PBE modes, setting this bit to 1 will transition the MCG into BLPE mode; in FBI mode, setting this bit to 1 will transition the MCG into BLPI mode. In any other MCG mode, LP bit has no affect.<br><br>0 FLL or PLL is not disabled in bypass modes.<br>1 FLL or PLL is disabled in bypass modes (lower power) |
| 0<br>IRCS   | Internal Reference Clock Select<br>Selects between the fast or slow internal reference clock source.<br><br>0 Slow internal reference clock selected.<br>1 Fast internal reference clock selected.  |

### 25.3.3 MCG Control 3 Register (MCG\_C3)

Address: 4006\_4000h base + 2h offset = 4006\_4002h

|       |        |    |    |    |    |    |    |    |
|-------|--------|----|----|----|----|----|----|----|
| Bit   | 7      | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | SCTRIM |    |    |    |    |    |    |    |
| Write | SCTRIM |    |    |    |    |    |    |    |
| Reset | x*     | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### MCG\_C3 field descriptions

| Field         | Description   |
|---------------|---|
| 7-0<br>SCTRIM | Slow Internal Reference Clock Trim Setting<br><br>SCTRIM <sup>1</sup> controls the slow internal reference clock frequency by controlling the slow internal reference clock period. The SCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.<br><br>An additional fine trim bit is available in C4 register as the SCFTRIM bit. Upon reset, this value is loaded with a factory trim value. |

### MCG\_C3 field descriptions (continued)

| Field | Description  |
|-------|--|
|       | If an SCTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register. |

1. A value for SCTRIM is loaded during reset from a factory programmed location.

### 25.3.4 MCG Control 4 Register (MCG\_C4)

#### NOTE

Reset values for DRST and DMX32 bits are 0.

Address: 4006\_4000h base + 3h offset = 4006\_4003h

| Bit   | 7     | 6        | 5 | 4      | 3  | 2  | 1  | 0       |
|-------|-------|----------|---|--------|----|----|----|---------|
| Read  | DMX32 | DRST_DRS |   | FCTRIM |    |    |    | SCFTRIM |
| Write |       |          |   |        |    |    |    |         |
| Reset | 0     | 0        | 0 | x*     | x* | x* | x* | x*      |

\* Notes:

- x = Undefined at reset.
- A value for FCTRIM is loaded during reset from a factory programmed location. x = Undefined at reset.

| Field           | Description   |
|-----------------|---|
| 6–5<br>DRST_DRS | <p>DCO Range Select</p> <p>The DRS bits select the frequency range for the FLL output, DCOOUT. When the LP bit is set, writes to the DRS bits are ignored. The DRST read field indicates the current frequency range for DCOOUT. The DRST field does not update immediately after a write to the DRS field due to internal synchronization between clock domains. See the DCO Frequency Range table for more details.</p> <p>00 Encoding 0 — Low range (reset default).<br/>           01 Encoding 1 — Mid range.<br/>           10 Encoding 2 — Mid-high range.<br/>           11 Encoding 3 — High range.</p> |
| 4–1<br>FCTRIM   | <p>Fast Internal Reference Clock Trim Setting</p> <p>FCTRIM <sup>1</sup> controls the fast internal reference clock frequency by controlling the fast internal reference clock period. The FCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.</p> <p>If an FCTRIM[3:0] value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.</p>  |
| 0<br>SCFTRIM    | <p>Slow Internal Reference Clock Fine Trim</p> <p>SCFTRIM <sup>2</sup> controls the smallest adjustment of the slow internal reference clock frequency. Setting SCFTRIM increases the period and clearing SCFTRIM decreases the period by the smallest amount possible.</p> <p>If an SCFTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this bit.</p>   |

1. A value for FCTRIM is loaded during reset from a factory programmed location.
2. A value for SCFTRIM is loaded during reset from a factory programmed location.

### 25.3.5 MCG Control 5 Register (MCG\_C5)

Address: 4006\_4000h base + 4h offset = 4006\_4004h

**25.3.7 MCG Status Register (MCG\_S)**

Address: 4006\_4000h base + 6h offset = 4006\_4006h

| Bit   | 7     | 6     | 5     | 4      | 3     | 2 | 1        | 0     |
|-------|-------|-------|-------|--------|-------|---|----------|-------|
| Read  | LOLS0 | LOCK0 | PLLST | IREFST | CLKST |   | OSCINIT0 | IRCST |
| Write |       |       |       |        |       |   |          |       |
| Reset | 0     | 0     | 0     | 1      | 0     | 0 | 0        | 0     |

**MCG\_S field descriptions**

| Field      | Description  |
|------------|--|
| 7<br>LOLS0 | <p>Loss of Lock Status</p> <p>This bit is a sticky bit indicating the lock status for the PLL. LOLS0 is set if after acquiring lock, the PLL output frequency has fallen outside the lock exit frequency tolerance, <math>D_{unt}</math>. LOLIE0 determines whether an interrupt request is made when LOLS0 is set. This bit is cleared by reset or by writing a logic 1 to it when set. Writing a logic 0 to this bit has no effect.</p> <p>0 PLL has not lost lock since LOLS0 was last cleared.<br/>           1 PLL has lost lock since LOLS0 was last cleared.</p>  |
| 6<br>LOCK0 | <p>Lock Status</p> <p>This bit indicates whether the PLL0 has acquired lock. Lock detection is disabled when not operating in either PBE or PEE mode unless PLLCLKEN0=1 and the MCG is not configured in BLPI or BLPE mode. While the PLL0 clock is locking to the desired frequency, MCGPLL0CLK and MCGPLL0CLK2X will be gated off until the LOCK0 bit gets asserted. If the lock status bit is set, changing the value of the PRDIV0[2:0] bits in the C5 register or the VDIV0[4:0] bits in the C6 register causes the lock status bit to clear and stay cleared until the PLL0 has reacquired lock. Loss of PLL0 reference clock will also cause the LOCK0 bit to clear until PLL0 has reacquired lock. Entry into LLS, VLPS, or regular Stop with PLLSTEN0=0 also causes the lock status bit to clear and stay cleared until the Stop mode is exited and the PLL0 has reacquired lock. Any time the PLL0 is enabled and the LOCK0 bit is cleared, the MCGPLL0CLK and MCGPLL0CLK2X will be gated off until the LOCK0 bit is asserted again.</p> |

### MCG\_S field descriptions (continued)

| Field         | Description   |
|---------------|---|
|               | 0 PLL is currently unlocked.<br>1 PLL is currently locked.  |
| 5<br>PLLST    | PLL Select Status<br><br>This bit indicates the clock source selected by PLLS. The PLLST bit does not update immediately after a write to the PLLS bit due to internal synchronization between clock domains.<br><br>0 Source of PLLS clock is FLL clock.<br>1 Source of PLLS clock is PLLCS output clock.  |
| 4<br>IREFST   | Internal Reference Status<br><br>This bit indicates the current source for the FLL reference clock. The IREFST bit does not update immediately after a write to the IREFS bit due to internal synchronization between clock domains.<br><br>0 Source of FLL reference clock is the external reference clock.<br>1 Source of FLL reference clock is the internal reference clock.  |
| 3–2<br>CLKST  | Clock Mode Status<br><br>These bits indicate the current clock mode. The CLKST bits do not update immediately after a write to the CLKS bits due to internal synchronization between clock domains.<br><br>00 Encoding 0 — Output of the FLL is selected (reset default).<br>01 Encoding 1 — Internal reference clock is selected.<br>10 Encoding 2 — External reference clock is selected.<br>11 Encoding 3 — Output of the PLL is selected.   |
| 1<br>OSCINIT0 | OSC Initialization<br><br>This bit, which resets to 0, is set to 1 after the initialization cycles of the crystal oscillator clock have completed. After being set, the bit is cleared to 0 if the OSC is subsequently disabled. See the OSC module's detailed description for more information.  |
| 0<br>IRCST    | Internal Reference Clock Status<br><br>The IRCST bit indicates the current source for the internal reference clock select clock (IRCSCLK). The IRCST bit does not update immediately after a write to the IRCS bit due to internal synchronization between clock domains. The IRCST bit will only be updated if the internal reference clock is enabled, either by the MCG being in a mode that uses the IRC or by setting the C1[IRCLKEN] bit .<br><br>0 Source of internal reference clock is the slow clock (32 kHz IRC).<br>1 Source of internal reference clock is the fast clock (4 MHz IRC). |

### 25.3.8 MCG Status and Control Register (MCG\_SC)

Address: 4006\_4000h base + 8h offset = 4006\_4008h

|       |      |      |      |          |        |   |   |       |
|-------|------|------|------|----------|--------|---|---|-------|
| Bit   | 7    | 6    | 5    | 4        | 3      | 2 | 1 | 0     |
| Read  | ATME | ATMS | ATMF | FLTPRSRV | FCRDIV |   |   | LOCS0 |
| Write |      |      |      |          |        |   |   |       |
| Reset | 0    | 0    | 0    | 0        | 0      | 0 | 1 | 0     |

**MCG\_SC field descriptions**

| Field         | Description  |
|---------------|--|
| 7<br>ATME     | <p>Automatic Trim Machine Enable</p> <p>Enables the Auto Trim Machine to start automatically trimming the selected Internal Reference Clock.</p> <p><b>NOTE:</b> ATME deasserts after the Auto Trim Machine has completed trimming all trim bits of the IRCS clock selected by the ATMS bit.</p> <p>Writing to C1, C3, C4, and SC registers or entering Stop mode aborts the auto trim operation and clears this bit.</p> <p>0 Auto Trim Machine disabled.<br/>1 Auto Trim Machine enabled.</p>  |
| 6<br>ATMS     | <p>Automatic Trim Machine Select</p> <p>Selects the IRCS clock for Auto Trim Test.</p> <p>0 32 kHz Internal Reference Clock selected.<br/>1 4 MHz Internal Reference Clock selected.</p>   |
| 5<br>ATMF     | <p>Automatic Trim Machine Fail Flag</p> <p>Fail flag for the Automatic Trim Machine (ATM). This bit asserts when the Automatic Trim Machine is enabled, ATME=1, and a write to the C1, C3, C4, and SC registers is detected or the MCG enters into any Stop mode. A write to ATMF clears the flag.</p> <p>0 Automatic Trim Machine completed normally.<br/>1 Automatic Trim Machine failed.</p>  |
| 4<br>FLTPRSRV | <p>FLL Filter Preserve Enable</p> <p>This bit will prevent the FLL filter values from resetting allowing the FLL output frequency to remain the same during clock mode changes where the FLL/DCO output is still valid. (Note: This requires that the FLL reference frequency to remain the same as what it was prior to the new clock mode switch. Otherwise FLL filter and frequency values will change.)</p> <p>0 FLL filter and FLL frequency will reset on changes to correct clock mode.<br/>1 FLL filter and FLL frequency retain their previous values during new clock mode change.</p> |
| 3-1<br>FCRDIV | <p>Fast Clock Internal Reference Divider</p> <p>Selects the amount to divide down the fast internal reference clock. The resulting frequency will be in the range 31.25 kHz to 4 MHz (Note: Changing the divider when the Fast IRC is enabled is not supported).</p> <p>000 Divide Factor is 1<br/>001 Divide Factor is 2.<br/>010 Divide Factor is 4.<br/>011 Divide Factor is 8.<br/>100 Divide Factor is 16<br/>101 Divide Factor is 32<br/>110 Divide Factor is 64<br/>111 Divide Factor is 128.</p>   |
| 0<br>LOCS0    | <p>OSC0 Loss of Clock Status</p> <p>The LOCS0 indicates when a loss of OSC0 reference clock has occurred. The LOCS0 bit only has an effect when CME0 is set. This bit is cleared by writing a logic 1 to it when set.</p>  |

### MCG\_S2 field descriptions

| Field           | Description   |
|-----------------|---|
| 7<br>LOLS1      | <p>Loss of Lock2 Status</p> <p>This bit is a sticky bit indicating the lock status for the PLL1. LOLS1 is set if after acquiring lock, the PLL1 output frequency has fallen outside the lock exit frequency tolerance, <math>D_{unt}</math>. LOLIE1 determines whether an interrupt request is made when LOLS1 is set. This bit is cleared by reset or by writing a logic 1 to it when set. Writing a logic 0 to this bit has no effect.</p> <p>0 PLL1 has not lost lock since LOLS1 was last cleared.<br/>1 PLL1 has lost lock since LOLS1 was last cleared.</p>   |
| 6<br>LOCK1      | <p>Lock1 Status</p> <p>This bit indicates whether PLL1 has acquired lock. PLL1 Lock detection is disabled when not operating in either PBE or PEE mode unless PLLCLKEN1=1 and the MCG is not configured in BLPI or BLPE mode. While the PLL1 clock is locking to the desired frequency, MCGPLL1CLK, MCGPLL1CLK2X, and MCGDDRCLK2X will be gated off until the LOCK1 bit gets asserted. If the lock status bit is set, changing the value of the PRDIV1[2:0] bits in the C8 register or the VDIV2[4:0] bits in the C9 register causes the lock status bit to clear and stay cleared until the PLL1 has reacquired lock. Loss of PLL1 reference clock will also cause the LOCK1 bit to clear until PLL1 has reacquired lock. Entry into LLS, VLPS, or regular Stop with PLLSTEN1=0 also causes the lock status bit to clear and stay cleared until Stop mode is exited and the PLL1 has reacquired lock. Any time the PLL1 is enabled and the LOCK1 bit is cleared, the MCGPLL1CLK, MCGPLL1CLK2X, and MCGDDRCLK2X will be gated off until the LOCK1 bit is asserted again.</p> <p>0 PLL1 is currently unlocked.<br/>1 PLL1 is currently locked.</p> |
| 5<br>Reserved   | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 4<br>PLLCST     | <p>PLL Clock Select Status</p> <p>The PLLCST indicates the PLL clock selected by PLLCS. The PLLCST bit does not updated immediately after a write to the PLLCS bit due internal synchronization between clock domains.</p> <p>0 Source of PLLCS is PLL0 clock.<br/>1 Source of PLLCS is PLL1 clock.</p>   |
| 3–2<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 1<br>OSCINIT1   | <p>OSC1 Initialization</p> <p>This bit is set after the initialization cycles of the 2nd crystal oscillator clock have completed. Refer to the Oscillator block guide for more details.</p>   |
| 0<br>LOCS2      | <p>OSC1 Loss of Clock Status</p> <p>This bit indicates when a loss of OSC1 external reference clock has occurred. LOCRE2 determines if a reset or interrupt is generated when LOCS2 is set. This bit is cleared by writing a logic 1 to it when set.</p> <p>0 No loss of OSC1 external reference clock has occurred.<br/>1 Loss of OSC1 external reference clock has occurred.</p>  |

## 25.4 Functional description

### 25.4.1 MCG mode state diagram

The nine states of the MCG are shown in the following figure and are described in [Table 25-22](#). The arrows indicate the permitted MCG mode transitions.

**Figure 25-18. MCG mode state diagram**

#### NOTE

- During exits from LLS or VLPS when the MCG is in PEE mode, the MCG will reset to PBE clock mode and the C1[CLKS] and S[CLKST] will automatically be set to 2'b10.
- If entering Normal Stop mode when the MCG is in PEE mode with PLLSTEN=0, the MCG will reset to PBE clock mode and C1[CLKS] and S[CLKST] will automatically be set to 2'b10.

## 25.4.1.1 MCG modes of operation

The MCG operates in one of the following modes.

### Note

The MCG restricts transitions between modes. For the permitted transitions, see [Figure 25-18](#).

**Table 25-22. MCG modes of operation**

| Mode                       | Description  |
|----------------------------|--|
| FLL Engaged Internal (FEI) | <p>FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 00 is written to C1[CLKS].</li> <li>• 1 is written to C1[IREFS].</li> <li>• 0 is written to C6[PLLS].</li> </ul> <p>In FEI mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the 32 kHz Internal Reference Clock (IRC). The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FEI mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN0] is set or C11[PLLCLKEN1] is set.</p>  |
| FLL Engaged External (FEE) | <p>FLL engaged external (FEE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 00 is written to C1[CLKS].</li> <li>• 0 is written to C1[IREFS].</li> <li>• C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz</li> <li>• 0 is written to C6[PLLS].</li> </ul> <p>In FEE mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the external reference clock. The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the external reference frequency, as specified by C1[FRDIV] and C2[RANGE]. See the C4[DMX32] bit description for more details. In FEE mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN0] is set or C11[PLLCLKEN1] is set.</p> |

**Table 25-22. MCG modes of operation (continued)**

| Mode                        | Description   |
|-----------------------------|---|
| FLL Bypassed Internal (FBI) | <p>FLL bypassed internal (FBI) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 01 is written to C1[CLKS].</li> <li>• 1 is written to C1[IREFS].</li> <li>• 0 is written to C6[PLLS]</li> <li>• 0 is written to C2[LP].</li> </ul> <p>In FBI mode, the MCGOUTCLK is derived either from the slow (32 kHz IRC) or fast (4 MHz IRC) internal reference clock, as selected by the C2[IRCS] bit. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the C2[IRCS] selected internal reference clock. The FLL clock (DCOCLK) is controlled by the slow internal reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FBI mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN0] is set or C11[PLLCLKEN1] is set.</p>  |
| FLL Bypassed External (FBE) | <p>FLL bypassed external (FBE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 10 is written to C1[CLKS].</li> <li>• 0 is written to C1[IREFS].</li> <li>• C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.</li> <li>• 0 is written to C6[PLLS].</li> <li>• 0 is written to C2[LP].</li> </ul> <p>In FBE mode, the MCGOUTCLK is derived from the OSCSEL external reference clock. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the external reference clock. The FLL clock (DCOCLK) is controlled by the external reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the divided external reference frequency. See the C4[DMX32] bit description for more details. In FBE mode, PLL0 and PLL1 are disabled in a low-power state unless C5[PLLCLKEN0] is set or C11[PLLCLKEN1] is set.</p> |
| PLL Engaged External (PEE)  | <p>PLL Engaged External (PEE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 00 is written to C1[CLKS].</li> <li>• 0 is written to C1[IREFS].</li> <li>• 1 is written to C6[PLLS].</li> </ul> <p>In PEE mode, the MCGOUTCLK is derived from the output of PLL0 or PLL1 (depending on the C11[PLLCS] bit) which are controlled by a selectable external reference clock. The selected PLL clock frequency locks to a multiplication factor, as specified by its corresponding VDIV, times the selected PLL reference frequency, as specified by its corresponding PRDIV. The PLL's programmable reference divider must be configured to produce a valid PLL reference clock. The FLL is disabled in a low-power state.</p>  |

**Table 25-22. MCG modes of operation (continued)**

| Mode | Description  |
|------|--|
| Stop | <p>Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the chapter that describes how modules are configured and MCG behavior during Stop recovery. Entering Stop mode, the FLL is disabled, and all MCG clock signals are static except in the following case:</p> <p>MCGPLL0CLK is active in Normal Stop mode when PLLSTEN0=1</p> <p>MCGPLL1CLK is active in Normal Stop mode when PLLSTEN1=1</p> <p>MCGIRCLK is active in Normal Stop mode when all the following conditions become true:</p> <ul style="list-style-type: none"> <li>• C1[IRCLKEN] = 1</li> <li>• C1[IREFSTEN] = 1</li> </ul> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• When entering Low Power Stop modes (LLS or VLPS) from PEE mode, on exit the MCG clock mode is forced to PBE clock mode. C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK0] bit will be cleared without setting S[LOLS0].</li> <li>• When entering Normal Stop mode from PEE mode and if C5[PLLSTEN0]=0, on exit the MCG clock mode is forced to PBE mode, the C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK0] bit will clear without setting S[LOLS0]. If C5[PLLSTEN0]=1, the S[LOCK0] bit will not get cleared and on exit the MCG will continue to run in PEE mode.</li> </ul> |

1. If entering VLPR mode, MCG has to be configured and enter BLPE mode or BLPI mode with the Fast IRC clock selected (C2[IRCS]=1). After it enters VLPR mode, writes to any of the MCG control registers that can cause an MCG clock mode switch to a non low power clock mode must be avoided.

### NOTE

For the chip-specific modes of operation, see the power management chapter of this MCU.

#### 25.4.1.2 MCG mode switching

C1[IREFS] can be changed at any time, but the actual switch to the newly selected reference clocks is shown by S[IREFST]. When switching between engaged internal and engaged external modes, the FLL will begin locking again after the switch is completed.

C1[CLKS] can also be changed at any time, but the actual switch to the newly selected clock is shown by S[CLKST]. If the newly selected clock is not available, the previous clock will remain selected.

The C4[DRST\_DRS] write bits can be changed at any time except when C2[LP] bit is 1. If C4[DRST\_DRS] write bits are changed while in FLL engaged internal (FEI) or FLL engaged external (FEE) mode, the MCGOUTCLK switches to the new selected DCO range within three clocks of the selected DCO clock. After switching to the new DCO

(indicated by the updated C4[DRST\_DRS] read bits), the FLL remains unlocked for several reference cycles. The FLL lock time is provided in the device data sheet as  $t_{\text{fll\_acquire}}$ .

## 25.4.2 Low-power bit usage

C2[LP] is provided to allow the FLL or PLL to be disabled and thus conserve power when these systems are not being used. C4[DRST\_DRS] cannot be written while C2[LP] is 1. However, in some applications, it may be desirable to enable the FLL or PLL and allow it to lock for maximum accuracy before switching to an engaged mode. Do this by writing 0 to C2[LP].

## 25.4.3 MCG Internal Reference Clocks

This module supports two internal reference clocks with nominal frequencies of 32 kHz (slow IRC) and 4 MHz (fast IRC). The fast IRC frequency can be divided down by programming of the FCRDIV to produce a frequency range of 32 kHz to 4 MHz.

### 25.4.3.1 MCG Internal Reference Clock

The MCG Internal Reference Clock (MCGIRCLK) provides a clock source for other on-chip peripherals and is enabled when C1[IRCLKEN]=1. When enabled, MCGIRCLK is driven by either the fast internal reference clock (4 MHz IRC which can be divided down by the FRDIV factors) or the slow internal reference clock (32 kHz IRC). The IRCS clock frequency can be re-targeted by trimming the period of its IRCS selected internal reference clock. This can be done by writing a new trim value to the C3[SCTRIM]:C4[SCFTRIM] bits when the slow IRC clock is selected or by writing a new trim value to C4[FCTRIM] when the fast IRC clock is selected. The internal reference clock period is proportional to the trim value written.

C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) and C4[FCTRIM] (if C2[IRCS]=1) bits affect the MCGOUTCLK frequency if the MCG is in FBI or BLPI modes.

C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) bits also affect the MCGOUTCLK frequency if the MCG is in FEI mode.

Additionally, this clock can be enabled in Stop mode by setting C1[IRCLKEN] and C1[IREFSTEN], otherwise this clock is disabled in Stop mode.

## 25.4.4 External Reference Clock

The MCG module can support an external reference clock in all modes. See the device datasheet for external reference frequency range. When C1[IREFS] is set, the external reference clock will not be used by the FLL or PLL. In these modes, the frequency can be equal to the maximum frequency the chip-level timing specifications will support.

If any of the CME bits are asserted the slow internal reference clock is enabled along with the enabled external clock monitor. For the case when C6[CME0]=1, a loss of clock is detected if the OSC0 external reference falls below a minimum frequency ( $f_{loc\_high}$  or  $f_{loc\_low}$  depending on C2[RANGE0]). For the case when C12[CME2]=1, a loss of clock is detected if the OSC1 external reference falls below a minimum frequency ( $f_{loc\_high}$  or  $f_{loc\_low}$  depending on C10[RANGE1]). For the case when C8[CME1]=1, a loss of clock is detected if the RTC external reference falls below a minimum frequency ( $f_{loc\_low}$ ).

### NOTE

All clock monitors must be disabled before entering these low-power modes: Stop, VLPS, VLPR, VLPW, LLS, and VLLSx.

On detecting a loss-of-clock event, the MCU generates a system reset if the respective LOCRE bit is set. Otherwise the MCG sets the respective LOCS bit and the MCG generates a LOCS interrupt request. In the case where a OSC0 or OSC1 loss of clock is detected, the respective PLL's LOCK status bit is cleared if the OSC clock that is lost was selected as the PLL reference clock.

## 25.4.5 MCG Fixed Frequency Clock

The MCG Fixed Frequency Clock (MCGFFCLK) provides a fixed frequency clock source for other on-chip peripherals; see the block diagram. This clock is driven by either the slow clock from the internal reference clock generator or the external reference clock from the Crystal Oscillator, divided by the FLL reference clock divider. The source of MCGFFCLK is selected by C1[IREFS].

This clock is synchronized to the peripheral bus clock and is valid only when its frequency is not more than 1/8 of the MCGOUTCLK frequency. When it is not valid, it is disabled and held high. The MCGFFCLK is not available when the MCG is in BLPI mode. This clock is also disabled in Stop mode. The FLL reference clock must be set within the valid frequency range for the MCGFFCLK.

## 25.4.6 MCG PLL clock

The MCG PLL Clocks (MCGPLL0CLK, MCGPLL0CLK2X, MCGDDRCLK, MCGPLL1CLK, MCGPLL1CLK2X) are available depending on the device's configuration of the MCG module and DDR interface. For more details, see the clock distribution chapter of this MCU. The MCGPLL0CLK is prevented from coming out of the MCG until it is enabled and S[LOCK0] is set. The MCGPLL1CLK is prevented from coming out of the MCG until it is enabled and S2[LOCK1] is set.

## 25.4.7 MCG Auto TRIM (ATM)

The MCG Auto Trim (ATM) is a MCG feature that when enabled, it configures the MCG hardware to automatically trim the MCG Internal Reference Clocks using an external clock as a reference. The selection between which MCG IRC clock gets tested and enabled is controlled by the ATC[ATMS] control bit (ATC[ATMS]=0 selects the 32 kHz IRC and ATC[ATMS]=1 selects the 4 MHz IRC). If 4 MHz IRC is selected for the ATM, a divide by 128 is enabled to divide down the 4 MHz IRC to a range of 31.250 kHz.

When MCG ATM is enabled by writing ATC[ATME] bit to 1, The ATM machine will start auto trimming the selected IRC clock. During the autotrim process, ATC[ATME] will remain asserted and will deassert after ATM is completed or an abort occurs. The MCG ATM is aborted if a write to any of the following control registers is detected : C1, C3, C4, or ATC or if Stop mode is entered. If an abort occurs, ATC[ATMF] fail flag is asserted.

The ATM machine uses the bus clock as the external reference clock to perform the IRC auto-trim. Therefore, it is required that the MCG is configured in a clock mode where the reference clock used to generate the system clock is the external reference clock such as FBE clock mode. The MCG must not be configured in a clock mode where selected IRC ATM clock is used to generate the system clock. The bus clock is also required to be running with in the range of 8–16 MHz.

To perform the ATM on the selected IRC, the ATM machine uses the successive approximation technique to adjust the IRC trim bits to generate the desired IRC trimmed frequency. The ATM SARs each of the ATM IRC trim bits starting with the MSB. For each trim bit test, the ATM uses a pulse that is generated by the ATM selected IRC clock to enable a counter that counts number of ATM external clocks. At end of each trim bit, the ATM external counter value is compared to the ATCV[15:0] register value. Based on the comparison result, the ATM trim bit under test will get cleared or stay asserted. This is done until all trim bits have been tested by ATM SAR machine.

Before the ATM can be enabled, the ATM expected count needs to be derived and stored into the ATCV register. The ATCV expected count is derived based on the required target Internal Reference Clock (IRC) frequency, and the frequency of the external reference clock using the following formula:

$$\text{ATCV Expected Count Value} = 21 * (\text{Fe} / \text{Fr})$$

- Fr = Target Internal Reference Clock (IRC) Trimmed Frequency
- Fe = External Clock Frequency

If the auto trim is being performed on the 4 MHz IRC, the calculated expected count value must be multiplied by 128 before storing it in the ATCV register. Therefore, the ATCV Expected Count Value for trimming the 4 MHz IRC is calculated using the following formula.

$$\text{Expected Count Value} = (\text{Fe} / \text{Fr}) * 21 * (128)$$

## 25.5 Initialization / Application information

This section describes how to initialize and configure the MCG module in an application.

The following sections include examples on how to initialize the MCG and properly switch between the various available modes.

### 25.5.1 MCG module initialization sequence

The MCG comes out of reset configured for FEI mode.

The internal reference will stabilize in  $t_{\text{irefstb}}$  microseconds before the FLL can acquire lock. As soon as the internal reference is stable, the FLL will acquire lock in  $t_{\text{fll\_acquire}}$  milliseconds.

#### 25.5.1.1 Initializing the MCG

Because the MCG comes out of reset in FEI mode, the only MCG modes that can be directly switched to upon reset are FEE, FBE, and FBI modes (see [Figure 25-18](#)). Reaching any of the other modes requires first configuring the MCG for one of these three intermediate modes. Care must be taken to check relevant status bits in the MCG status register reflecting all configuration changes within each mode.

To change from FEI mode to FEE or FBE modes, follow this procedure:

1. Enable the external clock source by setting the appropriate bits in C2 register.
2. Write to C1 register to select the clock mode.
  - If entering FEE mode, set C1[FRDIV] appropriately, clear C1[IREFS] bit to switch to the external reference, and leave C1[CLKS] at 2'b00 so that the output of the FLL is selected as the system clock source.
  - If entering FBE, clear C1[IREFS] to switch to the external reference and change C1[CLKS] to 2'b10 so that the external reference clock is selected as the system clock source. The C1[FRDIV] bits should also be set appropriately here according to the external reference frequency to keep the FLL reference clock in the range of 31.25 kHz to 39.0625 kHz. Although the FLL is bypassed, it is still on in FBE mode.
  - The internal reference can optionally be kept running by setting C1[IRCLKEN]. This is useful if the application will switch back and forth between internal and external modes. For minimum power consumption, leave the internal reference disabled while in an external clock mode.
3. Once the proper configuration bits have been set, wait for the affected bits in the MCG status register to be changed appropriately, reflecting that the MCG has moved into the proper mode.
  - If the MCG is in FEE, FBE, PEE, PBE, or BLPE mode, and C2[EREFS0] was also set in step 1, wait here for S[OSCINIT0] bit to become set indicating that the external clock source has finished its initialization cycles and stabilized.
  - If in FEE mode, check to make sure S[IREFST] is cleared before moving on.
  - If in FBE mode, check to make sure S[IREFST] is cleared and S[CLKST] bits have changed to 2'b10 indicating the external reference clock has been appropriately selected. Although the FLL is bypassed, it is still on in FBE mode.
4. Write to the C4 register to determine the DCO output (MCGFLLCLK) frequency range.
  - By default, with C4[DMX32] cleared to 0, the FLL multiplier for the DCO output is 640. For greater flexibility, if a mid-low-range FLL multiplier of 1280 is desired instead, set C4[DRST\_DRS] bits to 2'b01 for a DCO output frequency of 40 MHz. If a mid high-range FLL multiplier of 1920 is desired instead, set the C4[DRST\_DRS] bits to 2'b10 for a DCO output frequency of 60 MHz. If a high-range FLL multiplier of 2560 is desired instead, set the C4[DRST\_DRS] bits to 2'b11 for a DCO output frequency of 80 MHz.

- When using a 32.768 kHz external reference, if the maximum low-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b00 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 732 will be 24 MHz.
  - When using a 32.768 kHz external reference, if the maximum mid-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b01 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 1464 will be 48 MHz.
  - When using a 32.768 kHz external reference, if the maximum mid high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b10 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2197 will be 72 MHz.
  - When using a 32.768 kHz external reference, if the maximum high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b11 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2929 will be 96 MHz.
5. Wait for the FLL lock time to guarantee FLL is running at new C4[DRST\_DRS] and C4[DMX32] programmed frequency.

To change from FEI clock mode to FBI clock mode, follow this procedure:

1. Change C1[CLKS] bits in C1 register to 2'b01 so that the internal reference clock is selected as the system clock source.
2. Wait for S[CLKST] bits in the MCG status register to change to 2'b01, indicating that the internal reference clock has been appropriately selected.
3. Write to the C2 register to determine the IRCS output (IRCSCLK) frequency range.
  - By default, with C2[IRCS] cleared to 0, the IRCS selected output clock is the slow internal reference clock (32 kHz IRC). If the faster IRC is desired, set C2[IRCS] to 1 for a IRCS clock derived from the 4 MHz IRC source.

## 25.5.2 Using a 32.768 kHz reference

In FEE and FBE modes, if using a 32.768 kHz external reference, at the default FLL multiplication factor of 640, the DCO output (MCGFLLCLK) frequency is 20.97 MHz at low-range.

If C4[DRST\_DRS] bits are set to 2'b01, the multiplication factor is doubled to 1280, and the resulting DCO output frequency is 41.94 MHz at mid-low-range. If C4[DRST\_DRS] bits are set to 2'b10, the multiplication factor is set to 1920, and the resulting DCO output frequency is 62.91 MHz at mid high-range. If C4[DRST\_DRS] bits are set to 2'b11, the multiplication factor is set to 2560, and the resulting DCO output frequency is 83.89 MHz at high-range.

In FBI and FEI modes, setting C4[DMX32] bit is not recommended. If the internal reference is trimmed to a frequency above 32.768 kHz, the greater FLL multiplication factor could potentially push the microcontroller system clock out of specification and damage the part.

## 25.5.3 MCG mode switching

When switching between operational modes of the MCG, certain configuration bits must be changed in order to properly move from one mode to another.

Each time any of these bits are changed (C6[PLLS], C1[IREFS], C1[CLKS], C2[IRCS], or C2[EREFS0]), the corresponding bits in the MCG status register (PLLST, IREFST, CLKST, IRCST, or OSCINIT) must be checked before moving on in the application software.

Additionally, care must be taken to ensure that the reference clock divider (C1[FRDIV] and C5[PRDIV0]) is set properly for the mode being switched to. For instance, in PEE mode, if using a 16 MHz crystal, C5[PRDIV0] must be set to 3'b000 (divide-by-1) or 3'b001 (divide-by-2) to divide the external reference down to the required frequency between 8 and 16 MHz.

In FBE, FEE, FBI, and FEI modes, at any time, the application can switch the FLL multiplication factor between 640, 1280, 1920, and 2560 with C4[DRST\_DRS] bits. Writes to C4[DRST\_DRS] bits will be ignored if C2[LP]=1.

The table below shows MCGOUTCLK frequency calculations using C1[FRDIV], C5[PRDIV0], and C6[VDIV0] settings for each clock mode.

**Table 25-23. MCGOUTCLK Frequency Calculation Options**

| Clock Mode                         | $f_{\text{MCGOUTCLK}}^1$                  | Note  |
|------------------------------------|---|---|
| FEI (FLL engaged internal)         | $(f_{\text{int}} * F)$                    | Typical $f_{\text{MCGOUTCLK}} = 21$ MHz immediately after reset.                  |
| FEE (FLL engaged external)         | $(f_{\text{ext}} / \text{FLL\_R}) * F$    | $f_{\text{ext}} / \text{FLL\_R}$ must be in the range of 31.25 kHz to 39.0625 kHz |
| FBE (FLL bypassed external)        | OSCCLK                                    | OSCCLK / FLL_R must be in the range of 31.25 kHz to 39.0625 kHz                   |
| FBI (FLL bypassed internal)        | MCGIRCLK                                  | Selectable between slow and fast IRC  |
| PEE (PLL engaged external)         | $(\text{OSCCLK} / \text{PLL\_R}) * M / 2$ | OSCCLK / PLL_R must be in the range of 8 – 16 MHz                                 |
| PBE (PLL bypassed external)        | OSCCLK                                    | OSCCLK / PLL_R must be in the range of 8 – 16 MHz                                 |
| BLPI (Bypassed low power internal) | MCGIRCLK                                  | Selectable between slow and fast IRC  |
| BLPE (Bypassed low power external) | OSCCLK                                    |   |

1. FLL\_R is the reference divider selected by the C1[FRDIV] bits, PLL\_R is the reference divider selected by C5[PRDIV0] bits, F is the FLL factor selected by C4[DRST\_DRS] and C4[DMX32] bits, and M is the multiplier selected by C6[VDIV0] bits.

This section will include three mode switching examples using an 16 MHz external crystal. If using an external clock source less than 8 MHz, the MCG must not be configured for any of the PLL modes (PEE and PBE).

### 25.5.3.1 Example 1: Moving from FEI to PEE Mode with OSC0 as the source for the external crystal clock: External Crystal = 16 MHz, MCGOUTCLK frequency = 120 MHz

In this example, the MCG will move through the proper operational modes from FEI to PEE to achieve 120 MHz MCGOUTCLK frequency from 16 MHz external crystal reference. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

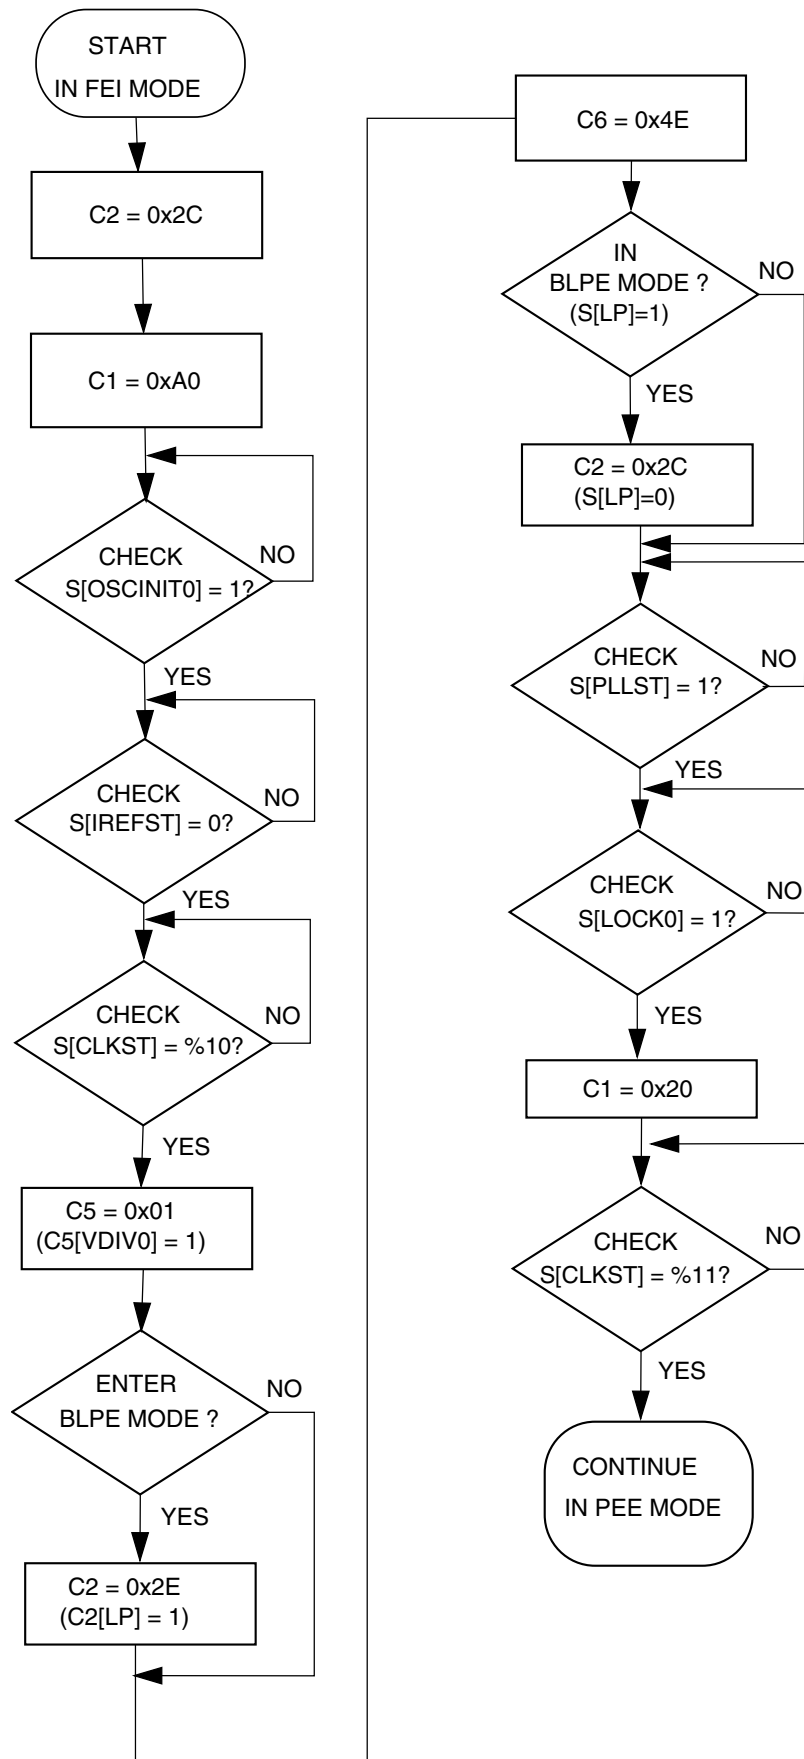

1. First, FEI must transition to FBE mode:
  - a. C2 = 0x2C
    - C2[RANGE0] set to 2'b10 because the frequency of 16 MHz is within the high frequency range.
    - C2[HGO0] set to 1 to configure the crystal oscillator for high gain operation.
    - C2[EREFS0] set to 1, because a crystal is being used.
  - b. C1 = 0xA0

- C1[CLKS] set to 2'b10 to select external reference clock as system clock source
  - C1[FRDIV] set to 3'b100, or divide-by-512 because  $16 \text{ MHz} / 512 = 31.25 \text{ kHz}$  which is in the 31.25 kHz to 39.0625 kHz range required by the FLL
  - C1[IREFS] cleared to 0, selecting the external reference clock and enabling the external oscillator.
- c. Loop until S[OSCINIT0] is 1, indicating the crystal selected by C2[EREFS0] has been initialized.
  - d. Loop until S[IREFST] is 0, indicating the external reference is the current source for the reference clock.
  - e. Loop until S[CLKST] is 2'b10, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then configure C5[PRDIV0] to generate correct PLL reference frequency.
    - a. C5 = 0x01
      - C5[PRDIV0] set to 3'b001, or divide-by-2 resulting in a pll reference frequency of  $16\text{MHz}/2 = 8 \text{ MHz}$ .
      - C5[PLLREFSEL0] set to 1'b0 to select the external reference clock from OSC0 as the reference clock to the PLL.
  3. Then, FBE must transition either directly to PBE mode or first through BLPE mode and then to PBE mode:
    - a. BLPE: If a transition through BLPE mode is desired, first set C2[LP] to 1.
    - b. BLPE/PBE: C6 = 0x4E
      - C6[PLLS] set to 1, selects the PLL. At this time, with a C5[PRDIV0] value of 3'b001, the PLL reference divider is 2 (see PLL External Reference Divide Factor table), resulting in a reference frequency of  $16 \text{ MHz} / 2 = 8 \text{ MHz}$ . In BLPE mode, changing the C6[PLLS] bit only prepares the MCG for PLL usage in PBE mode.
      - C6[VDIV] set to 5'b01110, or multiply-by-30 because  $8 \text{ MHz reference} * 30 = 240 \text{ MHz}$ . This is the MCGPLL0CLK2X frequency, which is the frequency of the VCO. This is divided by 2 to achieve the MCGPLL0CLK frequency of 120 MHz which is later used as the MCGOUTCLK frequency.

In BLPE mode, the configuration of the VDIV bits does not matter because the PLL is disabled. Changing them only sets up the multiply value for PLL usage in PBE mode.

- c. BLPE: If transitioning through BLPE mode, clear C2[LP] to 0 here to switch to PBE mode.
  - d. PBE: Loop until S[PLLST] is set, indicating that the current source for the PLLS clock is the PLL.
  - e. PBE: Then loop until S[LOCK0] is set, indicating that the PLL has acquired lock.
4. Lastly, PBE mode transitions into PEE mode:
- a. C1 = 0x20
    - C1[CLKS] set to 2'b00 to select the output of the PLL as the system clock source.
  - b. Loop until S[CLKST] are 2'b11, indicating that the PLL output is selected to feed MCGOUTCLK in the current clock mode.
    - Now, with PRDIV0 of divide-by-2, and C6[VDIV0] of multiply-by-30,  $MCGOUTCLK = [(16 \text{ MHz} / 2) * 30] / 2 = 120 \text{ MHz}$ .

**Figure 25-19. Flowchart of FEI to PEE mode transition using an 16 MHz crystal**  
 K61 Sub-Family Reference Manual, Rev. 3, November 2014

### 25.5.3.2 Example 2: Moving from PEE to BLPI mode: MCGOUTCLK frequency =32 kHz

In this example, the MCG will move through the proper operational modes from PEE mode with a 16 MHz crystal configured for a 120 MHz MCGOUTCLK frequency (see previous example) to BLPI mode with a 32 kHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, PEE must transition to PBE mode:
  - a.  $C1 = 0xA0$ 
    - $C1[CLKS]$  set to  $2'b10$  to switch the system clock source to the external reference clock.
  - b. Loop until  $S[CLKST]$  are  $2'b10$ , indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then, PBE must transition either directly to FBE mode or first through BLPE mode and then to FBE mode:
  - a. BLPE: If a transition through BLPE mode is desired, first set  $C2[LP]$  to 1.
  - b. BLPE/FBE:  $C6 = 0x00$ 
    - $C6[PLLS]$  clear to 0 to select the FLL. At this time, with  $C1[FRDIV]$  value of  $3'b100$ , the FLL divider is set to 512, resulting in a reference frequency of  $16\text{ MHz} / 512 = 31.25\text{ kHz}$ . If  $C1[FRDIV]$  was not previously set to  $3'b100$  (necessary to achieve required 31.25–39.06 kHz FLL reference frequency with an 16 MHz external source frequency), it must be changed prior to clearing  $C6[PLLS]$  bit. In BLPE mode, changing this bit only prepares the MCG for FLL usage in FBE mode. With  $C6[PLLS] = 0$ , the  $C6[VDIV0]$  value does not matter.
  - c. BLPE: If transitioning through BLPE mode, clear  $C2[LP]$  to 0 here to switch to FBE mode.
  - d. FBE: Loop until  $S[PLLST]$  is cleared, indicating that the current source for the PLLS clock is the FLL.
3. Next, FBE mode transitions into FBI mode:
  - a.  $C1 = 0x64$ 
    - $C1[CLKS]$  set to  $2'b01$  to switch the system clock to the internal reference clock.

- C1[IREFS] set to 1 to select the internal reference clock as the reference clock source.
  - C1[FRDIV] remain unchanged because the reference divider does not affect the internal reference.
- b. Loop until S[IREFST] is 1, indicating the internal reference clock has been selected as the reference clock source.
  - c. Loop until S[CLKST] are 2'b01, indicating that the internal reference clock is selected to feed MCGOUTCLK.
4. Lastly, FBI transitions into BLPI mode.
    - a. C2 = 0x22
      - C2[LP] is 1
      - C2[RANGE0], C2[HGO0], C2[EREFS0], C1[IRCLKEN], and C1[IREFSTEN] bits are ignored when the C1[IREFS] bit is set. They can remain set, or be cleared at this point.

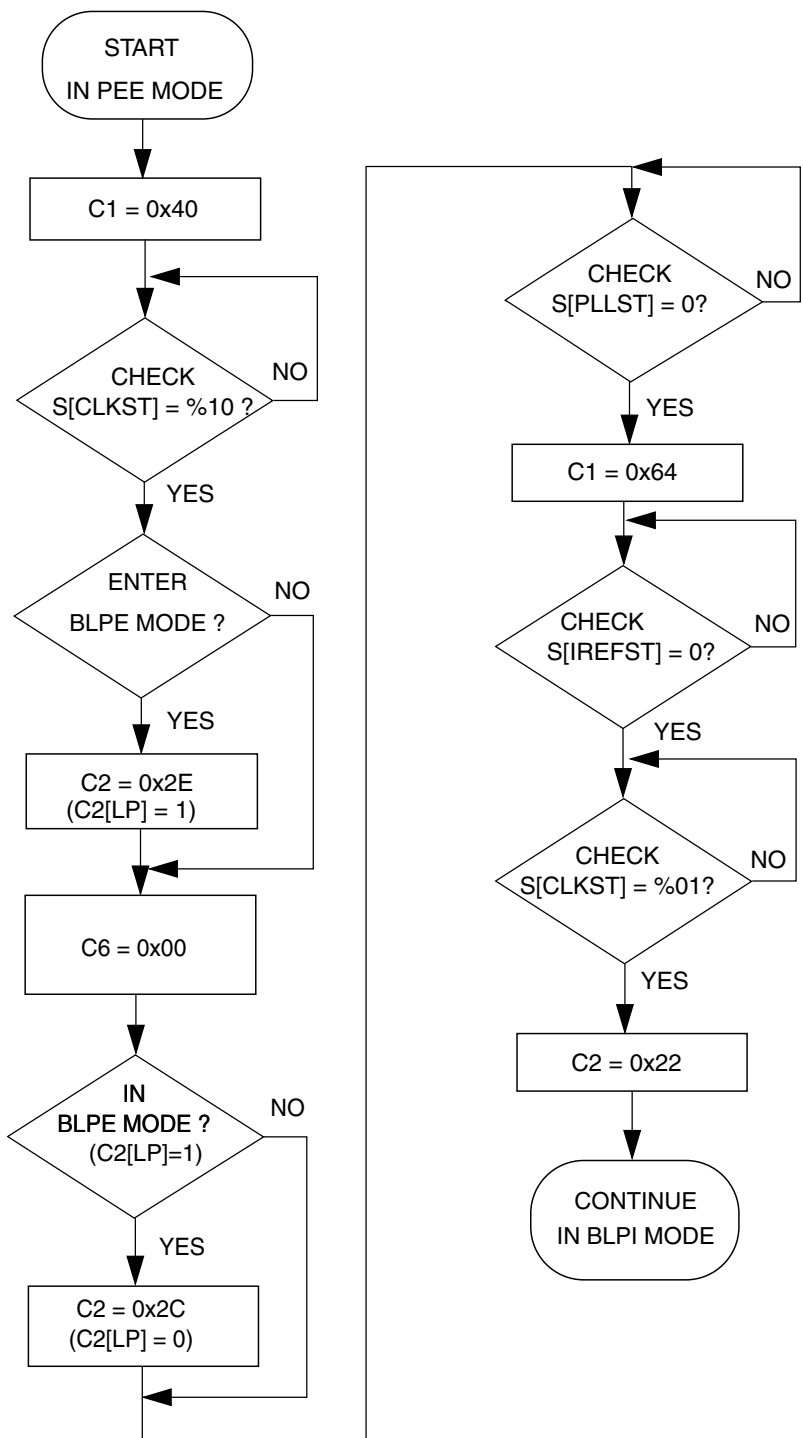

Figure 25-20. Flowchart of PEE to BLPI mode transition using an 16 MHz crystal

### 25.5.3.3 Example 3: Moving from BLPI to FEE mode

In this example, the MCG will move through the proper operational modes from BLPI mode at a 32 kHz MCGOUTCLK frequency running off the internal reference clock (see previous example) to FEE mode using a 16 MHz crystal configured for a 20 MHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, BLPI must transition to FBI mode.
  - a.  $C2 = 0x00$ 
    - $C2[LP]$  is 0
2. Next, FBI will transition to FEE mode.
  - a.  $C2 = 0x2C$ 
    - $C2[RANGE0]$  set to 2'b10 because the frequency of 16 MHz is within the high frequency range.
    - $C2[HGO0]$  set to 1 to configure the crystal oscillator for high gain operation.
    - $C2[EREFS0]$  set to 1, because a crystal is being used.
  - b.  $C1 = 0x20$ 
    - $C1[CLKS]$  set to 2'b00 to select the output of the FLL as system clock source.
    - $C1[FRDIV]$  remain at 3'b100, or divide-by-512 for a reference of  $16 \text{ MHz} / 512 = 31.25 \text{ kHz}$ .
    - $C1[IREFS]$  cleared to 0, selecting the external reference clock.
  - c. Loop until  $S[OSCINIT0]$  is 1, indicating the crystal selected by the  $C2[EREFS0]$  bit has been initialized.
  - d. Loop until  $S[IREFST]$  is 0, indicating the external reference clock is the current source for the reference clock.
  - e. Loop until  $S[CLKST]$  are 2'b00, indicating that the output of the FLL is selected to feed MCGOUTCLK.
  - f. Now, with a 31.25 kHz reference frequency, a fixed DCO multiplier of 640,  $MCGOUTCLK = 31.25 \text{ kHz} * 640 / 1 = 20 \text{ MHz}$ .
  - g. At this point, by default, the  $C4[DRST\_DRS]$  bits are set to 2'b00 and  $C4[DMX32]$  is cleared to 0. If the MCGOUTCLK frequency of 40 MHz is desired instead, set the  $C4[DRST\_DRS]$  bits to 0x01 to switch the FLL

multiplication factor from 640 to 1280. To return the MCGOUTCLK frequency to 20 MHz, set C4[DRST\_DRS] bits to 2'b00 again, and the FLL multiplication factor will switch back to 640.

Figure 25-21. Flowchart of BLPI to FEE mode transition using an 16 MHz crystal

## Chapter 26 Oscillator (OSC)

### 26.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The OSC module is a crystal oscillator. The module, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.

### 26.2 Features and Modes

Key features of the module are listed here.

- Supports 32 kHz crystals (Low Range mode)
- Supports 3–8 MHz crystals and resonators (High Range mode)
- Automatic Gain Control (AGC) to optimize power consumption in high frequency ranges 3–8 MHz using low-power mode
- High gain option in frequency ranges: 32 kHz, 3–8 MHz
- Voltage and frequency filtering to guarantee clock frequency and stability
- Optionally external input bypass clock from EXTAL signal directly
- One clock for MCU clock system
- Two clocks for on-chip peripherals that can work in Stop modes

[Functional Description](#) describes the module's operation in more detail.

## 26.3 Block Diagram

The OSC module uses a crystal or resonator to generate three filtered oscillator clock signals. Three clocks are output from OSC module: OSCCLK for MCU system, OSCERCLK for on-chip peripherals, and OSC32KCLK. The OSCCLK can only work in run mode. OSCERCLK and OSC32KCLK can work in low power modes. For the clock source assignments, refer to the clock distribution information of this MCU.

Refer to the chip configuration details for the external reference clock source in this MCU.

The figure found here shows the block diagram of the OSC module.

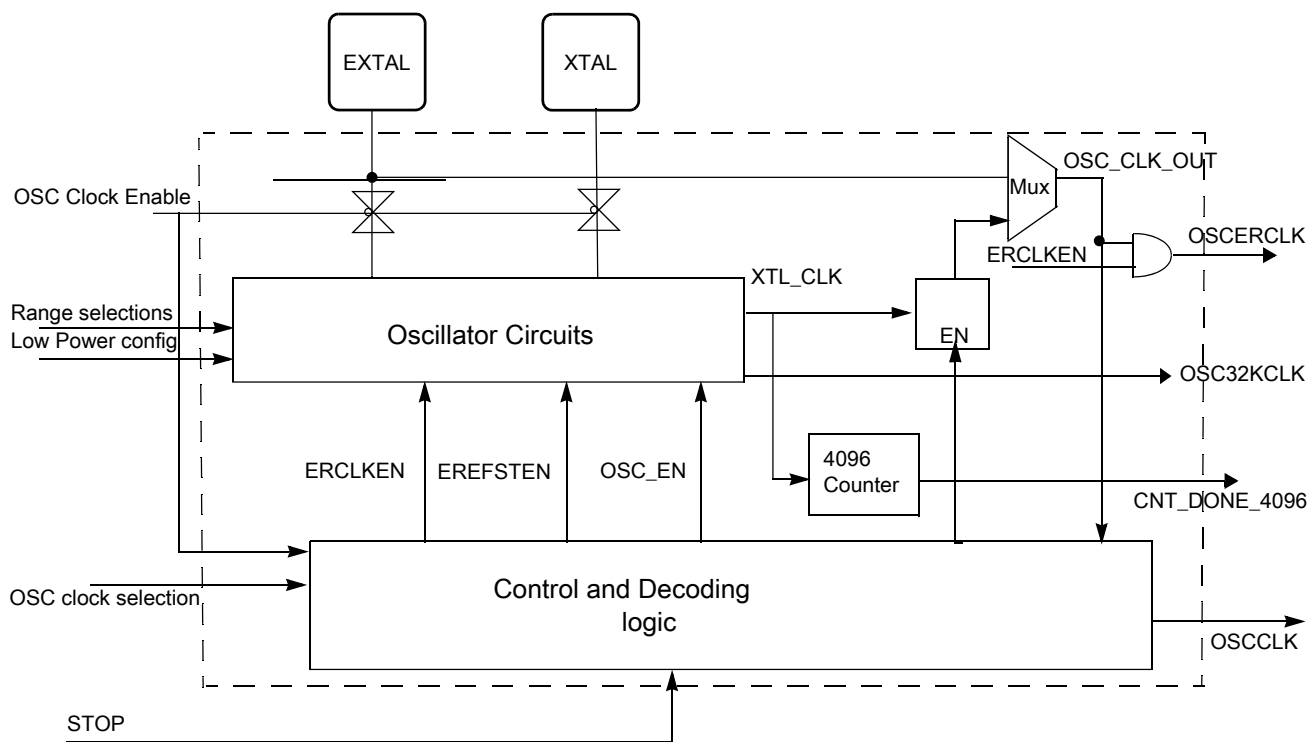

Figure 26-1. OSC Module Block Diagram

## 26.4 OSC Signal Descriptions

The table found here shows the user-accessible signals available for the OSC module.

Refer to signal multiplexing information for this MCU for more details.

**Table 26-1. OSC Signal Descriptions**

| Signal | Description                     | I/O |
|--------|---------------------------------|-----|
| EXTAL  | External clock/Oscillator input | I   |
| XTAL   | Oscillator output               | O   |

## 26.5 External Crystal / Resonator Connections

The connections for a crystal/resonator frequency reference are shown in the figures found here.

When using low-frequency, low-power mode, the only external component is the crystal or ceramic resonator itself. In the other oscillator modes, load capacitors ( $C_x$ ,  $C_y$ ) and feedback resistor ( $R_F$ ) are required. The following table shows all possible connections.

**Table 26-2. External Crystal/Resonator Connections**

| Oscillator Mode                      | Connections                              |
|--------------------------------------|--|
| Low-frequency (32 kHz), low-power    | Connection 1                             |
| Low-frequency (32 kHz), high-gain    | Connection 2/Connection 3 <sup>1</sup>   |
| High-frequency (3~32 MHz), low-power | Connection 1/Connection 3 <sup>2,2</sup> |
| High-frequency (3~32 MHz), high-gain | Connection 2/Connection 3 <sup>2</sup>   |

1. When the load capacitors ( $C_x$ ,  $C_y$ ) are greater than 30 pF, use Connection 3.
2. With the low-power mode, the oscillator has the internal feedback resistor  $R_F$ . Therefore, the feedback resistor must not be externally with the Connection 3.

**Figure 26-2. Crystal/Ceramic Resonator Connections - Connection 1**

**Figure 26-3. Crystal/Ceramic Resonator Connections - Connection 2**

**NOTE**

Connection 1 and Connection 2 should use internal capacitors as the load of the oscillator by configuring the CR[SCxP] bits.

**Figure 26-4. Crystal/Ceramic Resonator Connections - Connection 3**

## 26.6 External Clock Connections

In external clock mode, the pins can be connected as shown in the figure found here.

**NOTE**

XTAL can be used as a GPIO when the GPIO alternate function is configured for it.

Figure 26-5. External Clock Connections

## 26.7 Memory Map/Register Definitions

Some oscillator module register bits are typically incorporated into other peripherals such as MCG or SIM.

### 26.7.1 OSC Memory Map/Register Definition

OSC memory map

| Absolute address (hex) | Register name                  | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|--------------------------------|-----------------|--------|-------------|-----------------------------|
| 4006_5000              | OSC Control Register (OSC0_CR) | 8               | R/W    | 00h         | <a href="#">26.71.1/673</a> |
| 400E_5000              | OSC Control Register (OSC1_CR) | 8               | R/W    | 00h         | <a href="#">26.71.1/673</a> |

#### 26.71.1 OSC Control Register (OSCx\_CR)

#### NOTE

After OSC is enabled and starts generating the clocks, the configurations such as low power and frequency range, must not be changed.

Address: Base address + 0h offset

| Bit   | 7       | 6 | 5        | 4 | 3    | 2    | 1    | 0     |
|-------|---------|---|----------|---|------|------|------|-------|
| Read  | ERCLKEN | 0 | EREFSTEN | 0 | SC2P | SC4P | SC8P | SC16P |
| Write |         |   |          |   |      |      |      |       |
| Reset | 0       | 0 | 0        | 0 | 0    | 0    | 0    | 0     |

### OSCx\_CR field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>ERCLKEN  | <p>External Reference Enable</p> <p>Enables external reference clock (OSCERCLK).</p> <p>0 External reference clock is inactive.<br/>1 External reference clock is enabled.</p>   |

## 26.8 Functional Description

Functional details of the module can be found here.

## 26.8.1 OSC module states

The states of the OSC module are shown in the following figure. The states and their transitions between each other are described in this section.

Figure 26-9. OSC Module state diagram

### NOTE

XTL\_CLK is the clock generated internally from OSC circuits.

### 26.8.1.1 Off

The OSC enters the Off state when the system does not require OSC clocks. Upon entering this state, XTL\_CLK is static unless OSC is configured to select the clock from the EXTAL pad by clearing the external reference clock selection bit. For details regarding the external reference clock source in this MCU, refer to the chip configuration details. The EXTAL and XTAL pins are also decoupled from all other oscillator circuitry in this state. The OSC module circuitry is configured to draw minimal current.

### 26.8.1.2 Oscillator startup

The OSC enters startup state when it is configured to generate clocks (internally the OSC\_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit. In this state, the OSC module is enabled and oscillations are starting up, but have not yet stabilized. When the oscillation amplitude becomes large enough to pass through the input buffer, XTL\_CLK begins clocking the counter. When the counter reaches 4096 cycles of XTL\_CLK, the oscillator is considered stable and XTL\_CLK is passed to the output clock OSC\_CLK\_OUT.

### 26.8.1.3 Oscillator Stable

The OSC enters stable state when it is configured to generate clocks (internally the OSC\_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit and the counter reaches 4096 cycles of XTL\_CLK (when CNT\_DONE\_4096 is high). In this state, the OSC module is producing a stable output clock on OSC\_CLK\_OUT. Its frequency is determined by the external components being used.

### 26.8.1.4 External Clock mode

The OSC enters external clock state when it is enabled and external reference clock selection bit is cleared. For details regarding external reference clock source in this MCU, see the chip configuration details. In this state, the OSC module is set to buffer (with hysteresis) a clock from EXTAL onto the OSC\_CLK\_OUT. Its frequency is determined by the external clock being supplied.

## 26.8.2 OSC module modes

The OSC is a pierce-type oscillator that supports external crystals or resonators operating over the frequency ranges shown in [Table 26-9](#). These modes assume the following conditions: OSC is enabled to generate clocks (OSC\_EN=1), configured to generate clocks internally (MCG\_C2[EREFS] = 1), and some or one of the other peripherals (MCG, Timer, and so on) is configured to use the oscillator output clock (OSC\_CLK\_OUT).

**Table 26-9. Oscillator modes**

| Mode                            | Frequency Range  |
|---------------------------------|--|
| Low-frequency, high-gain        | $f_{osc\_lo}$ (32.768 kHz) up to $f_{osc\_lo}$ (39.0625 kHz) |
| High-frequency mode1, high-gain | $f_{osc\_hi\_1}$ (3 MHz) up to $f_{osc\_hi\_1}$ (8 MHz)      |
| High-frequency mode1, low-power |  |
| High-frequency mode2, high-gain | $f_{osc\_hi\_2}$ (8 MHz) up to $f_{osc\_hi\_2}$ (32 MHz)     |
| High-frequency mode2, low-power |  |

### NOTE

For information about low power modes of operation used in this chip and their alignment with some OSC modes, see the chip's Power Management details.

#### 26.8.2.1 Low-Frequency, High-Gain Mode

In Low-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes.

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

#### 26.8.2.2 Low-Frequency, Low-Power Mode

In low-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

In this mode, the amplifier inputs, gain-control input, and input buffer input are all capacitively coupled for leakage tolerance (not sensitive to the DC level of EXTAL).

Also in this mode, all external components except for the resonator itself are integrated, which includes the load capacitors and feedback resistor that biases EXTAL.

### 26.8.2.3 High-Frequency, High-Gain Mode

In high-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

### 26.8.2.4 High-Frequency, Low-Power Mode

In high-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

The oscillator input buffer in this mode is differential. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

## 26.8.3 Counter

The oscillator output clock (OSC\_CLK\_OUT) is gated off until the counter has detected 4096 cycles of its input clock (XTL\_CLK). After 4096 cycles are completed, the counter passes XTL\_CLK onto OSC\_CLK\_OUT. This counting timeout is used to guarantee output clock stability.

## 26.8.4 Reference clock pin requirements

The OSC module requires use of both the EXTAL and XTAL pins to generate an output clock in Oscillator mode, but requires only the EXTAL pin in External clock mode. The EXTAL and XTAL pins are available for I/O. For the implementation of these pins on this device, refer to the Signal Multiplexing chapter.

## 26.9 Reset

There is no reset state associated with the OSC module. The counter logic is reset when the OSC is not configured to generate clocks.

There are no sources of reset requests for the OSC module.

## 26.10 Low power modes operation

When the MCU enters Stop modes, the OSC is functional depending on CR[ERCLKEN] and CR[EREFSETN] bit settings. If both these bits are set, the OSC is in operation.

In Low Leakage Stop (LLS) modes, the OSC holds all register settings. If CR[ERCLKEN] and CR[EREFSTEN] are set before entry to Low Leakage Stop modes, the OSC is still functional in these modes. After waking up from Very Low Leakage Stop (VLLSx) modes, all OSC register bits are reset and initialization is required through software.

## 26.11 Interrupts

The OSC module does not generate any interrupts.

## Chapter 27

# RTC Oscillator (OSC32K)

### 27.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The RTC oscillator module provides the clock source for the RTC. The RTC oscillator module, in conjunction with an external crystal, generates a reference clock for the RTC.

#### 27.1.1 Features and Modes

The key features of the RTC oscillator are as follows:

- Supports 32 kHz crystals with very low power
- Consists of internal feed back resistor
- Consists of internal programmable capacitors as the  $C_{load}$  of the oscillator
- Automatic Gain Control (AGC) to optimize power consumption

The RTC oscillator operations are described in detail in [Functional Description](#) .

#### 27.1.2 Block Diagram

The following is the block diagram of the RTC oscillator.

Figure 27-1. RTC Oscillator Block Diagram

## 27.2 RTC Signal Descriptions

The following table shows the user-accessible signals available for the RTC oscillator. See the chip-level specification to find out which signals are actually connected to the external pins.

Table 27-1. RTC Signal Descriptions

| Signal  | Description       | I/O |
|---------|-------------------|-----|
| EXTAL32 | Oscillator Input  | I   |
| XTAL32  | Oscillator Output | O   |

### 27.2.1 EXTAL32 — Oscillator Input

This signal is the analog input of the RTC oscillator.

### 27.2.2 XTAL32 — Oscillator Output

This signal is the analog output of the RTC oscillator module.

## 27.3 External Crystal Connections

The connections with a crystal is shown in the following figure. External load capacitors and feedback resistor are not required.

**Figure 27-2. Crystal Connections**

## 27.4 Memory Map/Register Descriptions

RTC oscillator control bits are part of the RTC registers. Refer to RTC Control register RTC\_GP\_DATA\_REG in the chip-specific information section for more details.

## 27.5 Functional Description

As shown in [Figure 27-1](#), the module includes an amplifier which supplies the negative resistor for the RTC oscillator. The gain of the amplifier is controlled by the amplitude detector, which optimizes the power consumption. A schmitt trigger is used to translate the sine-wave generated by this oscillator to a pulse clock out, which is a reference clock for the RTC digital core.

The oscillator includes an internal feedback resistor of approximately 100 M $\Omega$  between EXTAL32 and XTAL32.

In addition, there are two programmable capacitors with this oscillator, which can be used as the Cload of the oscillator. The programmable range is from 0pF to 30pF.

## 27.6 Reset Overview

There is no reset state associated with the RTC oscillator.

## 27.7 Interrupts

The RTC oscillator does not generate any interrupts.

# Chapter 28

## Local Memory Controller

### 28.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Local Memory Controller provides the ARM® Cortex-M4™ processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

#### 28.1.1 Block Diagram

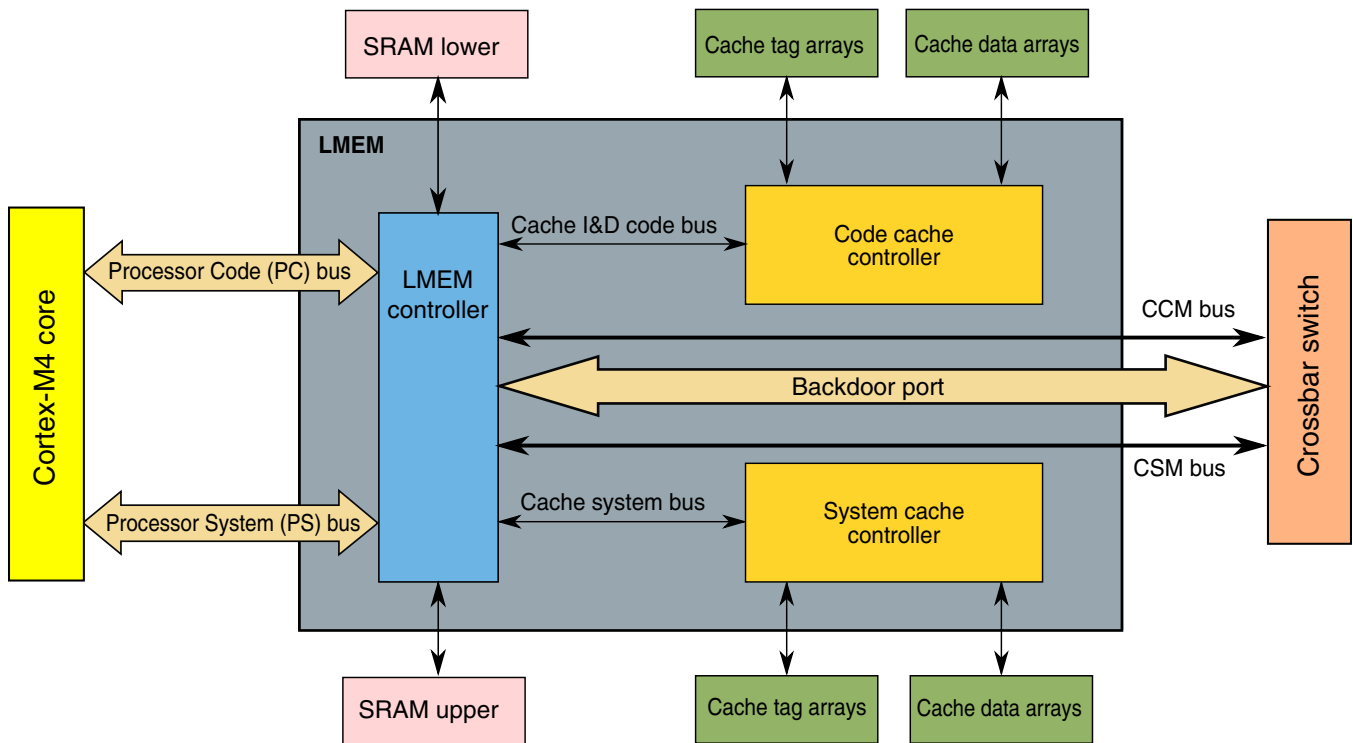

The Cortex-M4 processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000\_0000 through 0x1FFF\_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000\_0000 through 0xFFFF\_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes four memory controllers and their attached memories:

- SRAM lower (SRAM\_L) controller via the PC bus
- SRAM upper (SRAM\_U) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

**Figure 28-1. Local memory controller block diagram**

**NOTE**

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific and are specified in the device's Chip Configuration chapter.

**28.1.2 Cache features**

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports three modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
  - A write-through read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
  - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
  - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
  - A write-through write hit updates the cache hit data and writes to the output bus.
2. Write-back — access to address spaces with this cache mode are cacheable.
  - A write-back read miss on the input bus will cause a line read on the output bus of a 16-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.
  - A write-back read hit to a valid cache location will return data from the cache with no output bus access.
  - A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 16 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.

- 3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

## 28.2 Memory Map/Register Definition

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

### LMEM memory map

| Absolute address (hex) | Register name                                 | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|---|-----------------|--------|-------------|-----------------------------|
| E008_2000              | Cache control register (LMEM_PCCCR)           | 32              | R/W    | 0000_0000h  | <a href="#">28.2.1/688</a>  |

| 1<br>ENWRBUF      | Enable Write Buffer<br><br>0 Write buffer disabled<br>1 Write buffer enabled  |
| 0<br>ENCACHE      | Cache enable  |

Table continues on the next page...

### LMEM\_PCCCR field descriptions (continued)

| Field | Description    |
|-------|----------------|
| 0     | Cache disabled |
| 1     | Cache enabled  |

## 28.2.2 Cache line control register (LMEM\_PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008\_2000h base + 4h offset = E008\_2004h

### LMEM\_PCCLCR field descriptions

| Field             | Description   |
|-------------------|---|
| 31-28<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

Table continues on the next page...

**LMEM\_PCCLCR field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
| 27<br>LACC        | Line access type<br>0 Read<br>1 Write   |
| 26<br>LADSEL      | Line Address Select<br>When using the cache address, the way must also be specified in CLCR[WSEL].<br>When using the physical address, both ways are searched and the command is performed only if a hit.<br>0 Cache address<br>1 Physical address                              |
| 25–24<br>LCMD     | Line Command<br>00 Search and read or write<br>01 Invalidate<br>10 Push<br>11 Clear   |
| 23<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 22<br>LCWAY       | Line Command Way<br>Indicates the way used by the line command.   |
| 21<br>LCIMB       | Line Command Initial Modified Bit<br>If command used cache address and way, then this bit shows the initial state of the modified bit<br>If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero. |
| 20<br>LCIVB       | Line Command Initial Valid Bit<br>If command used cache address and way, then this bit shows the initial state of the valid bit<br>If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.          |
| 19–17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 16<br>TDSEL       | Tag/Data Select<br>Selects tag or data for search and read or write commands.<br>0 Data<br>1 Tag  |
| 15<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

| Field             | Description   |
|-------------------|---|
| 11–2<br>CACHEADDR | Cache address<br>CLCR[11:4] bits are used to access the tag arrays<br>CLCR[11:2] bits are used to access the data arrays  |
| 1<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 0<br>LGO          | Initiate Cache Line Command<br><br>Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active<br><br><b>NOTE:</b> This bit stays set until the command completes. Writing zero has no effect.<br><br><b>NOTE:</b> This bit is shared with CSAR[LGO]<br><br>0 Write: no effect. Read: no line command active.<br>1 Write: initiate line command indicated by bits 27-24. Read: line command active. |

### 28.2.3 Cache search address register (LMEM\_PCCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008\_2000h base + 8h offset = E008\_2008h

|       |         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

### LMEM\_PCCSAR field descriptions

| Field           | Description   |
|-----------------|---|
| 31–2<br>PHYADDR | Physical Address<br>PHYADDR represents bits [31:2] of the system address.<br>CSAR[31:12] bits are used for tag compare<br>CSAR[11:4] bits are used to access the tag arrays<br>CSAR[11:2] bits are used to access the data arrays |
| 1<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

Table continues on the next page...

### LMEM\_PCCSAR field descriptions (continued)

| Field    | Description   |
|----------|---|
| 0<br>LGO | <p>Initiate Cache Line Command</p> <p>Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active</p> <p><b>NOTE:</b> This bit stays set until the command completes. Writing zero has no effect.</p> <p><b>NOTE:</b> This bit is shared with CLCR[LGO]</p> <p>0 Write: no effect. Read: no line command active.<br/>1 Write: initiate line command indicated by bits CLCR[27:24]. Read: line command active.</p> |

### 28.2.4 Cache read/write value register (LMEM\_PCCVVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008\_2000h base + Ch offset = E008\_200Ch

### LMEM\_PCCVVR field descriptions

| Field        | Description   |
|--------------|---|
| 31–0<br>DATA | <p>Cache read/write Data</p> <p>For tag search, read or write:</p> <ul style="list-style-type: none"> <li>• CCVR[31:12] bits are used for tag array R/W value</li> <li>• CCVR[11:4] bits are used for tag set address on reads; unused on writes</li> <li>• CCVR[3:2] bits are reserved</li> </ul> <p>For data search, read or write:</p> <ul style="list-style-type: none"> <li>• CCVR[31:0] bits are used for data array R/W value</li> </ul> |

### 28.2.5 Cache regions mode register (LMEM\_PCCRMR)

The CRMR register allows you to demote the cache mode of various subregions within the device's memory map. Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state.

To maintain cache coherency, changes to the cache mode should be completed while the address space being changed is not being accessed or the cache is disabled. Before a cache mode change, complete a cache clear all command to push and invalidate any cache entries that may have changed.

### NOTE

The address/module assignment of the 16 subregions is device-specific and are detailed in the Chip Configuration section. Some of the regions may not be used (non-cacheable), and some regions may not be capable of write-back.

Address: E008\_2000h base + 20h offset = E008\_2020h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 28.2.7 Cache line control register (LMEM\_PSCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008\_2000h base + 804h offset = E008\_2804h

**LMEM\_PSCLCR field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–28<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 27<br>LACC        | Line access type<br>0 Read<br>1 Write   |
| 26<br>LADSEL      | Line Address Select<br>When using the cache address, the way must also be specified in CLCR[WSEL].<br>When using the physical address, both ways are searched and the command is performed only if a hit.<br>0 Cache address<br>1 Physical address                              |

## 28.2.8 Cache search address register (LMEM\_PSCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008\_2000h base + 808h offset = E008\_2808h

|       |         |    |    |    |    |    |    |    |  |    |    |    |    |    |    |    |    |     |

Read: line command active. |

### 28.2.9 Cache read/write value register (LMEM\_PSCCVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008\_2000h base + 80Ch offset = E008\_280Ch

#### LMEM\_PSCCVR field descriptions

| Field        | Description   |
|--------------|---|
| 31–0<br>DATA | <p>Cache read/write Data</p> <p>For tag search, read or write:</p> <ul style="list-style-type: none"> <li>• CCVR[31:12] bits are used for tag array R/W value</li> <li>• CCVR[11:4] bits are used for tag set address on reads; unused on writes</li> <li>• CCVR[3:2] bits are reserved</li> </ul> <p>For data search, read or write:</p> <ul style="list-style-type: none"> <li>• CCVR[31:0] bits are used for data array R/W value</li> </ul> |

### 28.2.10 Cache regions mode register (LMEM\_PSCRMR)

The CRMR register allows you to demote the cache mode of various subregions within the device's memory map. Demoting the cache mode reduces the cache function applied to a memory region from write-back to write-through to non-cacheable. After a region is demoted, its cache mode can only be raised by a reset, which returns it to its default state.

To maintain cache coherency, changes to the cache mode should be completed while the address space being changed is not being accessed or the cache is disabled. Before a cache mode change, complete a cache clear all command to push and invalidate any cache entries that may have changed.

#### NOTE

The address/module assignment of the 16 subregions is device-specific and are detailed in the Chip Configuration section. Some of the regions may not be used (non-cacheable), and some regions may not be capable of write-back.

Address: E008\_2000h base + 820h offset = E008\_2820h

## 28.3 Functional Description

### 28.3.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor Space (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

### 28.3.1.1 Processor Code accesses

Processor Code accesses are routed to the SRAM\_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

### 28.3.1.2 Processor System accesses

Processor Space accesses are routed to the SRAM\_U if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master1 port.

### 28.3.1.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM\_L or the SRAM\_U depending on their specific address.

## 28.3.2 SRAM Function

### 28.3.2.1 SRAM Configuration

[SRAM Configuration](#) shows how the SRAM controller is configured.

Figure 28-12. SRAM configuration

### 28.3.2.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM\_L and SRAM\_U.

The on-chip SRAM is implemented so the SRAM\_L and SRAM\_U ranges form a contiguous block in the memory map. As such:

- SRAM\_L is anchored at address 0x2000\_0000 and occupies the space below this address, that is, addresses < 0x2000\_0000
- SRAM\_U is anchored at address 0x2000\_0000 and occupies the space at and above this beginning address, that is, addresses ≥ 0x2000\_0000.

From equal-sized memories, valid address ranges for SRAM\_L and SRAM\_U are then defined as:

- SRAM\_L = [0x2000\_0000 - (SRAM\_size/2)] to 0x1FFF\_FFFF
- SRAM\_U = 0x2000\_0000 to [0x2000\_0000 + (SRAM\_size/2) - 1]

This is illustrated in [Figure 28-13](#).

**Figure 28-13. SRAM Arrays**

For example, for a device containing 64 KB of SRAM the ranges are:

- SRAM\_L: 0x1FFF\_8000 – 0x1FFF\_FFFF
- SRAM\_U: 0x2000\_0000 – 0x2000\_7FFF

### 28.3.2.3 SRAM accesses

The SRAM is split into two logical arrays that are 32-bits wide:

- SRAM\_L — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- SRAM\_U — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

[Figure 28-14](#) illustrates the SRAM accesses within the device.

**Figure 28-14. SRAM access diagram**

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

#### **NOTE**

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM\_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

#### **NOTE**

Burst-access cannot occur across the 0x2000\_0000 boundary that separates the two SRAM arrays. The two arrays should be treated as separate memory ranges for burst accesses.

### **28.3.3 Cache Function**

The caches on this device are structured as follows. Both caches have a 2-way set-associative cache structure with a total size of 8 KBytes. The caches have 32-bit address and data paths and a 16-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these 8-KByte caches, each cache TAG function uses two 256 x 22-bit RAM arrays and the cache DATA function uses two 1024 x 32-bit RAM arrays. The cache TAG entries store 20 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store four bytes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 8 KByte size = (256 sets) x (16-byte lines) x (2-way set-associative)

TAG:

- address[31:12] used in tag for compare (hit) logic
- address[11:4] used to select 1 of 256 sets
- address[3:0] not used

DATA

- address[31:12] not used
- address[11:4] used to select one of 256 sets
- address[3:2] used to select one of four 32-bit words within a set
- address[1:0] used to select the byte within the 32-bit word

## 28.3.4 Cache Control

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

### 28.3.4.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in [Table 28-12](#). Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

**Table 28-12. Cache Set Commands**

| CCR[27:24] |       |         |       | Command   |
|------------|-------|---------|-------|---|
| PUSH W1    | INVW1 | PUSH W0 | INVW0 |   |
| 0          | 0     | 0       | 0     | NOP   |
| 0          | 0     | 0       | 1     | Invalidate all way 0  |
| 0          | 0     | 1       | 0     | Push all way 0  |
| 0          | 0     | 1       | 1     | Clear all way 0   |
| 0          | 1     | 0       | 0     | Invalidate all way 1  |
| 0          | 1     | 0       | 1     | Invalidate all way 1; invalidate all way 0 (invalidate cache) |
| 0          | 1     | 1       | 0     | Invalidate all way 1; push all way 0                          |
| 0          | 1     | 1       | 1     | Invalidate all way 1; clear all way 0                         |
| 1          | 0     | 0       | 0     | Push all way 1  |
| 1          | 0     | 0       | 1     | Push all way 1; invalidate all way 0                          |
| 1          | 0     | 1       | 0     | Push all way 1; push all way 0 (push cache)                   |
| 1          | 0     | 1       | 1     | Push all way 1; clear all way 0                               |
| 1          | 1     | 0       | 0     | Clear all way 1   |
| 1          | 1     | 0       | 1     | Clear all way 1; invalidate all way 0                         |
| 1          | 1     | 1       | 0     | Clear all way 1; push all way 0                               |
| 1          | 1     | 1       | 1     | Clear all way 1; clear all way 0 (clear cache)                |

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500\_0003 will invalidate the cache and enable the cache and write buffer.

### 28.3.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

## Functional Description

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by bits [11:4] of the physical address. If they hit, the commands perform their action on the hit way.

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts as a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

**Table 28-13. Cache Line Commands**

| CLCR[27:24] |        |      | Command                             |
|-------------|--------|------|-------------------------------------|
| LACC        | LADSEL | LCMD |                                     |
| 0           | 0      | 00   | Search by cache address and way     |
| 0           | 0      | 01   | Invalidate by cache address and way |
| 0           | 0      | 10   | Push by cache address and way       |
| 0           | 0      | 11   | Clear by cache address and way      |
| 0           | 1      | 00   | Search by physical address          |
| 0           | 1      | 01   | Invalidate by physical address      |
| 0           | 1      | 10   | Push by physical address            |
| 0           | 1      | 11   | Clear by physical address           |
| 1           | 0      | 00   | Write by cache address and way      |
| 1           | 0      | 01   | Reserved, NOP                       |
| 1           | 0      | 10   | Reserved, NOP                       |
| 1           | 0      | 11   | Reserved, NOP                       |
| 1           | 1      | xx   | Reserved, NOP                       |

### 28.3.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,

- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

#### 28.3.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
  - Place the command in CLCR[27:24]
  - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

#### 28.3.4.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB]) is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

**Table 28-14. Line command results**

| CLCR[22:20] |       |       | For cache address commands | For physical address commands |
|-------------|-------|-------|----------------------------|-------------------------------|
| LCWAY       | LCIMB | LCIVB |                            |                               |
| 0           | 0     | 0     | Way 0 line was invalid     | No hit                        |
| 0           | 0     | 1     | Way 0 valid, not modified  | Way 0 valid, not modified     |
| 0           | 1     | 0     | Way 0 line was invalid     | No hit                        |
| 0           | 1     | 1     | Way 0 valid and modified   | Way 0 valid and modified      |
| 1           | 0     | 0     | Way 1 line was invalid     | No hit                        |
| 1           | 0     | 1     | Way 1 valid, not modified  | Way 1 valid, not modified     |
| 1           | 1     | 0     | Way 1 line was invalid     | No hit                        |
| 1           | 1     | 1     | Way 1 valid and modified   | Way 1 valid and modified      |

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

### 28.3.4.3 Special considerations when using the cache with low power modes

If the cache is enabled, entry into a low power mode could interrupt a cache operation in progress, leading to corruption of the cache contents. In order to avoid this situation the following code sequence should be used for entry into low power modes:

```

LMEM_PCCLCR = 0x09000001;
LMEM_PSCLCR = 0x09000001;

/* Wait for cache command to complete */
While (LMEM_PCCLCR & 1);

/* Wait for cache command to complete */
While (LMEM_PSCLCR & 1);

Asm("DSB");
Asm("WFI");

Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");
Asm("NOP");

```

The code sequence above must be executed from a non-cached memory location, such as SRAM\_L (recommended). The NOPs in the sequence can be replaced with other code as long as that code doesn't make reference to cached addresses.

# Chapter 29

## Flash Memory Controller (FMC)

### 29.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Flash Memory Controller (FMC) is a memory acceleration unit that provides:

- an interface between the device and the multi-bank nonvolatile memory.
- buffers that can accelerate flash memory and FlexNVM data transfers.

#### 29.1.1 Overview

The Flash Memory Controller manages the interface between the device and the multi-bank flash memory. The FMC receives status information detailing the configuration of the memory and uses this information to ensure a proper interface. The following table shows the supported 8-bit, 16-bit, and 32-bit read/write operations.

| Flash memory type                  | Read | Write          |
|------------------------------------|------|----------------|
| Program flash memory               | x    | — <sup>1</sup> |
| FlexNVM used as data flash memory  | x    | — <sup>1</sup> |
| FlexNVM and FlexRAM used as EEPROM | x    | x              |

1. A write operation to program flash memory or to FlexNVM used as data flash memory results in a bus error.

In addition, the FMC provides three separate mechanisms for accelerating the interface between the device and the flash memory. A 128-bit speculation buffer can prefetch the next 128-bit flash memory location, and both a 4-way, 4-set cache (with 128-bit entries) and a single-entry 128-bit buffer can store previously accessed flash memory or FlexNVM data for quick access times.

## 29.1.2 Features

The FMC's features include:

- Interface between the device and the multi-bank flash memory and FlexMemory:
  - 8-bit, 16-bit, and 32-bit read operations to program flash memory and FlexNVM used as data flash memory.
  - 8-bit, 16-bit, and 32-bit read and write operations to FlexNVM and FlexRAM used as EEPROM.
  - Read accesses to consecutive 32-bit spaces in memory return the second, third, and fourth read data with no wait states. The memory returns 128 bits via the 32-bit bus access.
  - Crossbar master access protection for setting no access, read only access, write only access, or read/write access for each crossbar master.
- Acceleration of data transfer from program flash memory and FlexMemory to the device:
  - 128-bit prefetch speculation buffer with controls for instruction/data access per master
  - 4-way, 4-set, 128-bit line size cache for a total of sixteen 128-bit entries with controls for replacement algorithm and lock per way
  - Single-entry buffer with enable
  - Invalidation control for the speculation buffer and the single-entry buffer

## 29.2 Modes of operation

The FMC only operates when the device accesses the flash memory or FlexMemory.

For any device power mode where the flash memory or FlexMemory cannot be accessed, the FMC is disabled.

## 29.3 External signal description

The FMC has no external signals.

## 29.4 Memory map and register descriptions

The programming model consists of the FMC control registers and the program visible cache (data and tag/valid entries).

### NOTE

Program the registers only while the flash controller is idle (for example, execute from RAM). Changing configuration settings while a flash access is in progress can lead to non-deterministic behavior.

**Table 29-2. FMC register access**

| Registers                                   | Read access                               |         | Write access                      |                   |
|---|---|---------|-----------------------------------|-------------------|
|   | Mode                                      | Length  | Mode                              | Length            |
| Control registers (PFAPR, PFB01CR, PFB23CR) | Supervisor (privileged) mode or user mode | 32 bits | Supervisor (privileged) mode only | 8, 16, or 32 bits |
| Cache registers                             | Supervisor (privileged) mode or user mode | 32 bits | Supervisor (privileged) mode only | 32 bits           |

### NOTE

Accesses to unimplemented registers within the FMC's address space return a bus error.

The 16 cache entries, both data and tag/valid, can be read at any time.

### NOTE

System software is required to maintain memory coherence when any segment of the flash cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

The cache is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. The following table elaborates on the tag/valid and data entries.

**Table 29-3. Program visible cache registers**

| Cache storage | Based at offset | Contents of 32-bit read       | Nomenclature   | Nomenclature example  |
|---------------|-----------------|-------------------------------|--|---|
| Tag           | 100h            | 12'h0, tag[19:6], 5'h0, valid | In TAGVDWxSy, x denotes the way and y denotes the set. | TAGVDW2S3 is the 14-bit tag and 1-bit valid for cache entry way 2, set 3. |

*Table continues on the next page...*

**Table 29-3. Program visible cache registers (continued)**

| Cache storage | Based at offset | Contents of 32-bit read                            | Nomenclature  | Nomenclature example   |
|---------------|-----------------|--|---|--|
| Data          | 200h            | One of the four longwords in a 128-bit cache entry | In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost). | For data entry way 1, set 3, DATAW1S3UM represents bits [127:96], DATAW1S3MU represents bits [95:64], DATAW1S3ML represents bits [63:32], and DATAW1S3LM represents bits [31:0]. |

| Field                  | Description  |
|------------------------|--|
| 23–20<br>CINV_WAY[3:0] | <p>Cache Invalidate Way x</p> <p>These bits determine if the given cache way is to be invalidated (cleared). When a bit within this field is written, the corresponding cache way is immediately invalidated: the way's tag, data, and valid contents are cleared. This field always reads as zero.</p> <p>Cache invalidation takes precedence over locking. The cache is invalidated by system reset. System software is required to maintain memory coherency when any segment of the flash memory is programmed or erased. Accordingly, cache invalidations must occur after a programming or erase event is completed and before the new memory image is accessed.</p> <p>The bit setting definitions are for each bit in the field.</p> <p>0 No cache way invalidation for the corresponding cache<br/>1 Invalidate cache way for the corresponding cache: clear the tag, data, and vld bits of ways selected</p> |
| 19<br>S_B_INV          | <p>Invalidate Prefetch Speculation Buffer</p> <p>This bit determines if the FMC's prefetch speculation buffer and the single entry page buffer are to be invalidated (cleared). When this bit is written, the speculation buffer and single entry buffer are immediately cleared. This bit always reads as zero.</p> <p>0 Speculation buffer and single entry buffer are not affected.<br/>1 Invalidate (clear) speculation buffer and single entry buffer.</p>  |
| 18–17<br>B01MW[1:0]    | <p>Bank 0-1 Memory Width</p> <p>This read-only field defines the width of the bank 0-1 memory.</p> <p>00 32 bits<br/>01 64 bits<br/>10 128 bits<br/>11 Reserved</p>  |

| 0<br>valid        | 1-bit valid for cache entry   |

### 29.4.8 Cache Data Storage (uppermost word) (FMC\_DATAW0SnUM)

The cache of sixteen 128-bit entries is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost). This section represents data for the uppermost word (bits [127:96]) of all 4 sets (n=0-3) in way 0.

Address: 4001\_F000h base + 200h offset + (16d × i), where i=0d to 3d

#### FMC\_DATAW0SnUM field descriptions

| Field                | Description                 |
|----------------------|-----------------------------|
| 31–0<br>data[127:96] | Bits [127:96] of data entry |

### 29.4.9 Cache Data Storage (mid-upper word) (FMC\_DATAW0SnMU)

The cache of sixteen 128-bit entries is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost). This section represents data for the mid-upper word (bits [95:64]) of all 4 sets (n=0-3) in way 0.

Address: 4001\_F000h base + 204h offset + (16d × i), where i=0d to 3d

#### FMC\_DATAW0SnMU field descriptions

| Field               | Description                |
|---------------------|----------------------------|
| 31–0<br>data[95:64] | Bits [95:64] of data entry |

### 29.4.10 Cache Data Storage (mid-lower word) (FMC\_DATAW0SnML)

The cache of sixteen 128-bit entries is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost). This section represents data for the mid-lower word (bits [63:32]) of all 4 sets (n=0-3) in way 0.

Address: 4001\_F000h base + 208h offset + (16d × i), where i=0d to 3d

#### FMC\_DATAW0SnML field descriptions

| Field               | Description                |
|---------------------|----------------------------|
| 31–0<br>data[63:32] | Bits [63:32] of data entry |

### 29.4.11 Cache Data Storage (lowermost word) (FMC\_DATAW0SnLM)

The cache of sixteen 128-bit entries is a 4-way, set-associative cache with 4 sets. The ways are numbered 0-3 and the sets are numbered 0-3. In DATAWxSyUM, DATAWxSyMU, DATAWxSyML, and DATAWxSyLM, x denotes the way, y denotes the set, and the final two letters identify the word: UM (uppermost), MU (mid-upper), ML (mid-lower), and LM (lowermost). This section represents data for the lowermost word (bits [31:0]) of all 4 sets (n=0-3) in way 0.

Address: 4001\_F000h base + 20Ch offset + (16d × i), where i=0d to 3d

| 31–0<br>data[31:0] | Bits [31:0] of data entry |

## 29.5 Functional description

The FMC is a flash acceleration unit with flexible buffers for user configuration. Besides managing the interface between the device and the flash memory and FlexMemory, the FMC can be used to restrict access from crossbar switch masters and customize the cache and buffers to provide single-cycle system-clock data-access times. Whenever a hit occurs for the prefetch speculation buffer, the cache, or the single-entry buffer, the requested data is transferred within a single system clock.

### 29.5.1 Default configuration

Upon system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory or FlexMemory:

- Crossbar masters 0-2 have read access to banks 0-3.
- Crossbar masters 0-2 have write access to a portion of banks 2-3 when FlexNVM is used with FlexRAM as EEPROM.
- Prefetch support for data and instructions is enabled for crossbar masters 0-2.
- The cache is configured for least recently used (LRU) replacement for all four ways.
- The cache is configured for data or instruction replacement.
- The single-entry buffer is enabled.

### 29.5.2 Configuration options

Though the default configuration provides a high degree of flash acceleration, advanced users may desire to customize the FMC buffer configurations to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory or FlexMemory is being accessed. Instead, change the control registers with a routine executing from RAM in supervisor mode.

The FMC's cache and buffering controls within PFB01CR and PFB23CR allow the tuning of resources to suit particular applications' needs. The cache and two buffers are each controlled individually. The register controls enable buffering and prefetching per memory bank pair (banks 0-1 and 2-3) and access type (instruction fetch or data reference). The cache also supports three types of LRU replacement algorithms:

- LRU per set across all four ways,
- LRU with ways [0-1] for instruction fetches and ways [2-3] for data fetches, and
- LRU with ways [0-2] for instruction fetches and way [3] for data fetches.

As an application example: if both instruction fetches and data references are accessing banks 0-1, control is available to send instruction fetches, data references, or both to the cache or the single-entry buffer. Likewise, speculation can be enabled or disabled for either type of access. If both instruction fetches and data references are cached, the cache's way resources may be divided in several ways between the instruction fetches and data references.

In another application example, the cache can be configured for replacement from banks 0-1, while the single-entry buffer can be enabled for banks 2-3 only. This configuration is ideal for applications that use banks 0-1 for program space and banks 2-3 for data space.

### 29.5.3 Wait states

Because the core, crossbar switch, and bus masters can be clocked at a higher frequency than the flash clock, flash memory accesses that do not hit in the speculation buffer or cache usually require wait states. The number of wait states depends on both of the following:

1. the ratio of the core clock to the flash clock, and
2. the phase relationship of the core clock and flash clock at the time the read is requested.

The ratio of the core clock to the flash clock is equal to the value of  $\text{PFB01CR}[\text{B01RWSC}] + 1$  for banks 0-1 and to the value of  $\text{PFB23CR}[\text{B23RWSC}] + 1$  for banks 2-3.

For example, in a system with a 4:1 core-to-flash clock ratio, a read that does not hit in the speculation buffer or the cache can take between 4 and 7 core clock cycles to complete.

- The best-case scenario is a period of 4 core clock cycles because a read from the flash memory takes 1 flash clock, which translates to 4 core clocks.
- The worst-case scenario is a period of 7 core clock cycles, consisting of 4 cycles for the read operation and 3 cycles of delay to align the core and flash clocks.
  - A delay to align the core and flash clocks might occur because you can request a read cycle on any core clock edge, but that edge does not necessarily align with a flash clock edge where the read can start.
  - In this case, the read operation is delayed by a number of core clocks equal to the core-to-flash clock ratio minus one:  $4 - 1 = 3$ . That is, 3 additional core clock cycles are required to synchronize the clocks before the read operation can start.

All wait states and synchronization delays are handled automatically by the Flash Memory Controller. No direct user configuration is required or even allowed to set up the flash wait states.

## 29.5.4 Speculative reads

The FMC has a single buffer that reads ahead to the next word in the flash memory if there is an idle cycle. Speculative prefetching is programmable for each bank for instruction and/or data accesses using the B01DPE and B01IPE fields of PFB01CR and the B23DPE and B23IPE fields of PFB23CR. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

When speculative reads are enabled, the FMC immediately requests the next sequential address after a read completes. By requesting the next word immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

For example, consider the following scenario:

- Assume a system with a 4:1 core-to-flash clock ratio and with speculative reads enabled.
- The core requests eight sequential longwords in back-to-back requests, meaning there are no core cycle delays except for stalls waiting for flash memory data to be returned.
- None of the data is already stored in the cache or speculation buffer.

In this scenario, the sequence of events for accessing the eight longwords is as follows:

1. The first longword read requires 4 to 7 core clocks. See [Wait states](#) for more information.
2. Due to the 128-bit data bus of the flash memory, the second longword read takes only 1 core clock because the data is already available inside the FMC. For the same reason, the third and fourth longword reads each take only 1 core clock.
3. Accessing the fifth longword requires 1 core clock cycle. The flash memory read itself takes 4 clocks, but the access starts immediately after the first read. As a result, 3 clocks for this access overlap with the second, third, and fourth longword reads from the core.
4. Reading the sixth, seventh, and eighth longwords takes only 1 clock each because the data is already available inside the FMC.

## 29.6 Initialization and application information

The FMC does not require user initialization. Flash acceleration features are enabled by default.

The FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly. As a result, if an application is executing flash memory commands, the FMC's cache might need to be disabled and/or flushed to prevent the possibility of returning stale data. Use the PFB01CR[CINV\_WAY] field to invalidate the cache in this manner.

## Chapter 30

# Flash Memory Module (FTFE)

### 30.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FTFE module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- For FlexNVM devices: FlexNVM for data store and additional code store
- For FlexNVM devices: FlexRAM for high-endurance data store or traditional RAM
- For program flash only devices: Programming acceleration RAM to speed flash programming

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The FTFE module includes a memory controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

#### CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased with security disabled. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that each flash block or sector be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

### 30.1.1 Features

The FTFE module includes the following features.

#### NOTE

See the device's Chip Configuration details for the exact amount of flash memory available on your device.

#### 30.1.1.1 Program Flash Memory Features

- Sector size of 4 Kbytes
- Program flash protection scheme prevents accidental program or erase of stored data
- Automated, built-in, program and erase algorithms with verify
- Section programming for faster bulk programming times
- For devices containing only program flash memory: Read access to one program flash block is possible while programming or erasing data in another program flash block
- For devices containing FlexNVM memory: Read access to one program flash block is possible while programming or erasing data in another program flash block, data flash block, or FlexRAM

#### 30.1.1.2 FlexNVM memory features

When FlexNVM is partitioned for data flash memory (on devices that contain FlexNVM memory):

- Sector size of 4 Kbytes
- Protection scheme prevents accidental program or erase of stored data

- Automated, built-in program and erase algorithms with verify
- Section programming for faster bulk programming times
- Read access to one data flash block possible while programming or erasing data in another program flash block or data flash block

### 30.1.1.3 Programming Acceleration RAM features

- For devices with only program flash memory: RAM to support section programming

### 30.1.1.4 FlexRAM features

For devices with FlexNVM memory:

- Memory that can be used as traditional RAM or as high-endurance EEPROM storage
- Up to 16 Kbytes of FlexRAM configured for EEPROM or traditional RAM operations
- When configured for EEPROM:
  - Protection scheme prevents accidental program or erase of data written for EEPROM
  - Built-in hardware emulation scheme to automate EEPROM record maintenance functions
  - Programmable EEPROM data set size and FlexNVM partition code facilitating EEPROM memory endurance trade-offs
  - Supports FlexRAM aligned writes of 1, 2, or 4 bytes at a time
  - Read access to FlexRAM possible while programming or erasing data in the program or data flash memory
- When configured for traditional RAM:
  - Read and write access possible to the FlexRAM while programming or erasing data in the program or data flash memory

### 30.1.1.5 Other FTFE module features

- Internal high-voltage supply generator for flash memory program and erase operations
- Optional interrupt generation upon flash command completion
- Supports MCU security mechanisms which prevent unauthorized access to the flash memory contents

### 30.1.2 Block diagram

The block diagram of the FTFE module is shown in the following figure.

For devices with FlexNVM feature:

**Figure 30-1. FTFE block diagram**

For devices that contain only program flash:

Figure 30-2. FTFE block diagram

### 30.1.3 Glossary

**Command write sequence** — A series of MCU writes to the Flash FCCOB register group that initiates and controls the execution of Flash algorithms that are built into the FTFE module.

**Data flash memory** — Partitioned from the FlexNVM block, the data flash memory provides nonvolatile storage for user data, boot code, and additional code store.

**Data flash sector** — The data flash sector is the smallest portion of the data flash memory that can be erased.

**EEPROM** — Using a built-in filing system, the FTFE module emulates the characteristics of an EEPROM by effectively providing a high-endurance, byte-writeable (program and erase) NVM.

**EEPROM backup data header** — The EEPROM backup data header is comprised of a 64-bit field found in EEPROM backup data memory which contains information used by the EEPROM filing system to determine the status of a specific EEPROM backup flash sector.

**EEPROM backup data record** — The EEPROM backup data record is comprised of a 7-bit status field, a 13-bit address field, and a 32-bit data field found in EEPROM backup data memory which is used by the EEPROM filing system. If the status field indicates a record is valid, the data field is mirrored in the FlexRAM at a location determined by the address field.

**EEPROM backup data memory** — Partitioned from the FlexNVM block, EEPROM backup data memory provides nonvolatile storage for the EEPROM filing system representing data written to the FlexRAM requiring highest endurance.

**EEPROM backup data sector** — The EEPROM backup data sector contains one EEPROM header and up to 255 EEPROM backup data records, which are used by the EEPROM filing system.

**Endurance** — The number of times that a flash memory location can be erased and reprogrammed.

**FCCOB (Flash Common Command Object)** — A group of flash registers that are used to pass command, address, data, and any associated parameters to the memory controller in the FTFE module.

**Flash block** — A macro within the FTFE module which provides the nonvolatile memory storage.

**FlexMemory** — FTFE configuration that supports data flash, EEPROM, and FlexRAM.

**FlexNVM Block** — The FlexNVM block can be configured to be used as data flash memory, EEPROM backup flash memory, or a combination of both.

**FlexRAM** — The FlexRAM refers to a RAM, dedicated to the FTFE module, that can be configured to store EEPROM data or as traditional RAM. When configured for EEPROM, valid writes to the FlexRAM generates a new EEPROM backup data record stored in the EEPROM backup flash memory.

**FTFE Module** — All flash blocks plus a flash management unit providing high-level control and an interface to MCU buses.

**IFR** — Nonvolatile information register found in each flash block, separate from the main memory array.

**NVM** — Nonvolatile memory. A memory technology that maintains stored data during power-off. The flash array is an NVM using NOR-type flash memory technology.

**NVM Normal Mode** — An NVM mode that provides basic user access to FTFE resources. The CPU or other bus masters initiate flash program and erase operations (or other flash commands) using writes to the FCCOB register group in the FTFE module.

**NVM Special Mode** — An NVM mode enabling external, off-chip access to the memory resources in the FTFE module. A reduced flash command set is available when the MCU is secured. See the Chip Configuration details for information on when this mode is used.

**Double-Phrase** — 128 bits of data with an aligned double-phrase having byte-address[3:0] = 0000.

**Phrase** — 64 bits of data with an aligned phrase having byte-address[2:0] = 000.

**Longword** — 32 bits of data with an aligned longword having byte-address[1:0] = 00.

**Word** — 16 bits of data with an aligned word having byte-address[0] = 0.

**Program flash** — The program flash memory provides nonvolatile storage for vectors and code store.

**Program flash sector** — The smallest portion of the program flash memory (consecutive addresses) that can be erased.

**Retention** — The length of time that data can be kept in the NVM without experiencing errors upon readout. Since erased (1) states are subject to degradation just like programmed (0) states, the data retention limit may be reached from the last erase operation (not from the programming time).

**RWW**— Read-While-Write. The ability to simultaneously read from one memory resource while commanded operations are active in another memory resource.

**Section program buffer** — Lower quarter of the programming acceleration FlexRAM allocated for storing large amounts of data for programming via the Program Section command.

**Secure** — An MCU state conveyed to the FTFE module as described in the Chip Configuration details for this device. In the secure state, reading and changing NVM contents is restricted.

## 30.2 External signal description

The FTFE module contains no signals that connect off-chip.

## 30.3 Memory map and registers

This section describes the memory map and registers for the FTFE module. Data read from unimplemented memory space in the FTFE module is undefined. Writes to unimplemented or reserved memory space (registers) in the FTFE module are ignored.

### 30.3.1 Flash configuration field description

The program flash memory contains a 16-byte flash configuration field that stores default protection settings (loaded on reset) and security information that allows the MCU to restrict access to the FTFE module.

| Flash Configuration Field Byte Address | Size (Bytes) | Field Description   |
|--|--------------|---|
| 0x0_0400 - 0x0_0407                    | 8            | Backdoor Comparison Key. Refer to <a href="#">Verify Backdoor Access Key command</a> and <a href="#">Unsecuring the MCU Using Backdoor Key Access</a> .       |
| 0x0_0408 - 0x0_040B                    | 4            | Program flash protection bytes. Refer to the description of the Program Flash Protection Registers (FPROT0-3).  |
| 0x0_040F                               | 1            | Program flash only devices: Reserved<br>FlexNVM devices: Data flash protection byte. Refer to the description of the Data Flash Protection Register (FDPROT). |
| 0x0_040E                               | 1            | Program flash only devices: Reserved<br>FlexNVM devices: EEPROM protection byte. Refer to the description of the EEPROM Protection Register (FEPROT).         |
| 0x0_040D                               | 1            | Flash nonvolatile option byte. Refer to the description of the Flash Option Register (FOPT).  |
| 0x0_040C                               | 1            | Flash security byte. Refer to the description of the Flash Security Register (FSEC).  |

### 30.3.2 Program flash 0 IFR map

The program flash 0 IFR is a 1 Kbyte nonvolatile information memory that can be read freely, but the user has no erase and limited program capabilities (see the Read Once, Program Once, and Read Resource commands in [Read Once Command](#), [Program Once command](#) and [Read Resource Command](#)). The contents of the program flash 0 IFR are summarized in the following table and further described in the subsequent paragraphs.

The program flash 0 IFR is located within the program flash 0 memory block.

| Address Range | Size (Bytes) | Field Description  |
|---------------|--------------|--------------------|
| 0x000 – 0x3BF | 960          | Reserved           |
| 0x3C0 – 0x3FF | 64           | Program Once Field |

### 30.3.2.1 Program Once field

The Program Once field in the program flash 0 IFR provides 64 bytes of user data storage separate from the program flash 0 main array. The user can program the Program Once field one time only as there is no program flash IFR erase mechanism available to the user. The Program Once field can be read any number of times. This section of the program flash 0 IFR is accessed in 8 byte records using the Read Once and Program Once commands (see [Read Once Command](#) and [Program Once command](#)).

### 30.3.3 Data flash 0 IFR map

The following only applies to devices with FlexNVM.

The data flash 0 IFR is a 1 Kbyte nonvolatile information memory that can be read and erased, but the user has limited program capabilities in the data flash 0 IFR (see the Program Partition command in [Program Partition command](#), the Erase All Blocks command in [Erase All Blocks Command](#), and the Read Resource command in [Read Resource Command](#)). The contents of the data flash 0 IFR are summarized in the following table and further described in the subsequent paragraphs.

The data flash 0 IFR is located within the data flash 0 memory block.

| Address Range               | Size (Bytes) | Field Description      |
|-----------------------------|--------------|------------------------|
| 0x00 – 0x3FB, 0x3FE – 0x3FF | 1022         | Reserved               |
| 0x3FD                       | 1            | EEPROM Data Set Size   |
| 0x3FC                       | 1            | FlexNVM Partition Code |

#### 30.3.3.1 EEPROM Data Set Size

The EEPROM data set size byte in the data flash 0 IFR supplies information which determines the amount of FlexRAM used in each of the available EEPROM subsystems. To program the EEERST, EEESPLIT and EEESIZE values, see the Program Partition command described in [Program Partition command](#).

**Table 30-1. EEPROM Data Set Size**

| Data flash IFR: 0x03FD |        |          |   |         |   |     |
|------------------------|--------|----------|---|---------|---|-----|
| 7                      | 6      | 5        | 4 | 3       | 2 | 1 0 |
| 1                      | 1      | EEESPLIT |   | EEESIZE |   |     |
| 1                      | EEERST | EEESPLIT |   | EEESIZE |   |     |

**Table 30-2. EEPROM Data Set Size Field Description**

| Field                | Description  |
|----------------------|--|
| 7-6<br>7<br>Reserved | This read-only bitfield is reserved and must always be written as one.   |
| 6<br>EEERST          | <p><b>EEPROM Load on Reset</b> — Determines whether the flash reset sequence takes time to load the FlexRAM with valid EEPROM data.</p> <p>'0' = FlexRAM is not loaded with valid EEPROM data during the flash reset sequence (see the Set FlexRAM Function command described in <a href="#">Set FlexRAM Function command</a> to load the FlexRAM with valid EEPROM data)</p> <p>'1' = FlexRAM is loaded with valid EEPROM data during the flash reset sequence</p>  |
| 5-4<br>EESPLIT       | This read-only bitfield is reserved and each bit will always read as one.  |
| 3-0<br>EESIZE        | <p><b>EEPROM Size</b> — Encoding of the total available FlexRAM for EEPROM use.</p> <p><b>NOTE:</b> EESIZE must be 0 bytes (1111b) when the FlexNVM partition code (<a href="#">FlexNVM partition code</a>) is set to 'No EEPROM'.</p> <p>'0000' = 16,384 Bytes<br/>           '0001' = 8,192 Bytes<br/>           '0010' = 4,096 Bytes<br/>           '0011' = 2,048 Bytes<br/>           '0100' = 1,024 Bytes<br/>           '0101' = 512 Bytes<br/>           '0110' = 256 Bytes<br/>           '0111' = 128 Bytes<br/>           '1000' = 64 Bytes<br/>           '1001' = Reserved32 Bytes<br/>           '1010' = Reserved<br/>           '1011' = Reserved<br/>           '1100' = Reserved<br/>           '1101' = Reserved<br/>           '1110' = Reserved<br/>           '1111' = 0 Bytes</p> |

### 30.3.3.2 FlexNVM partition code

The FlexNVM partition code byte in the data flash 0 IFR supplies a code which specifies how to split the FlexNVM block between data flash memory and EEPROM backup memory supporting EEPROM functions. To program the DEPART value, see the Program Partition command described in [Program Partition command](#).

**Table 30-3. FlexNVM partition code**

| Data Flash IFR: 0x03FC      |   |   |   |        |   |   |   |
|-----------------------------|---|---|---|--------|---|---|---|
| 7                           | 6 | 5 | 4 | 3      | 2 | 1 | 0 |
| 1                           | 1 | 1 | 1 | DEPART |   |   |   |
| = Unimplemented or Reserved |   |   |   |        |   |   |   |

**Table 30-4. FlexNVM partition code field description**

| Field           | Description   |                       |                    |                       |      |     |   |      |          |          |      |          |          |      |          |          |      |     |    |      |     |     |      |   |     |      |          |          |      |   |     |      |          |          |      |          |          |      |          |          |      |    |     |      |     |     |      |     |   |      |     |   |
|-----------------|---|-----------------------|--------------------|-----------------------|------|-----|---|------|----------|----------|------|----------|----------|------|----------|----------|------|-----|----|------|-----|-----|------|---|-----|------|----------|----------|------|---|-----|------|----------|----------|------|----------|----------|------|----------|----------|------|----|-----|------|-----|-----|------|-----|---|------|-----|---|
| 7-4<br>Reserved | This read-only bitfield is reserved and must always be written as one.  |                       |                    |                       |      |     |   |      |          |          |      |          |          |      |          |          |      |     |    |      |     |     |      |   |     |      |          |          |      |   |     |      |          |          |      |          |          |      |          |          |      |    |     |      |     |     |      |     |   |      |     |   |

### 30.3.4 Register descriptions

The FTFE module contains a set of memory-mapped control and status registers.

#### NOTE

While a command is running (FSTAT[CCIF]=0), register writes are not accepted to any register except FCNFG and FSTAT. The no-write rule is relaxed during the start-up reset

sequence, prior to the initial rise of CCIF. During this initialization period the user may write any register. All register writes are also disabled (except for registers FCNFG and FSTAT) whenever an erase suspend request is active (FCNFG[ERSSUSP]=1).

### FTFE memory map

| Absolute address (hex) | Register name                                       | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|---|-----------------|--------|-------------|-----------------------------|
| 4002_0000              | Flash Status Register (FTFE_FSTAT)                  | 8               | R/W    | 00h         | <a href="#">30.34.1/761</a> |

**30.34.1 Flash Status Register (FTFE\_FSTAT)**

The FSTAT register reports the operational status of the FTFE module.

The CCIF, RDCOLERR, ACCERR, and FPVIOL bits are readable and writable. The MGSTAT0 bit is read only. The unassigned bits read 0 and are not writable.

**NOTE**

When set, the Access Error (ACCERR) and Flash Protection Violation (FPVIOL) bits in this register prevent the launch of any more commands or writes to the FlexRAM (when EEERDY is set) until the flag is cleared (by writing a one to it).

Address: 4002\_0000h base + 0h offset = 4002\_0000h

| Bit   | 7    | 6        | 5      | 4      | 3 | 2 | 1 | 0       |
|-------|------|----------|--------|--------|---|---|---|---------|
| Read  | CCIF | RDCOLERR | ACCERR | FPVIOL |   | 0 |   | MGSTAT0 |
| Write | w1c  | w1c      | w1c    | w1c    |   |   |   |         |
| Reset | 0    | 0        | 0      | 0      | 0 | 0 | 0 | 0       |

**FTFE\_FSTAT field descriptions**

| Field     | Description  |
|-----------|--|
| 7<br>CCIF | <p>Command Complete Interrupt Flag</p> <p>The CCIF flag indicates that a FTFE command or EEPROM file system operation has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command, and CCIF stays low until command completion or command violation. The CCIF flag is also cleared by a successful write to FlexRAM while enabled for EEE, and CCIF stays low until the EEPROM file system has created the associated EEPROM data record.</p> <p>The CCIF bit is reset to 0 but is set to 1 by the memory controller at the end of the reset initialization sequence. Depending on how quickly the read occurs after reset release, the user may or may not see the 0 hardware reset value.</p> <p>0 FTFE command or EEPROM file system operation in progress<br/>                     1 FTFE command or EEPROM file system operation has completed</p> |

*Table continues on the next page...*

**FTFE\_FSTAT field descriptions (continued)**

| Field           | Description  |
|-----------------|--|
| 6<br>RDCOLERR   | <p>FTFE Read Collision Error Flag</p> <p>The RDCOLERR error bit indicates that the MCU attempted a read from an FTFE resource that was being manipulated by an FTFE command (CCIF=0). Any simultaneous access is detected as a collision error by the block arbitration logic. The read data in this case cannot be guaranteed. The RDCOLERR bit is cleared by writing a 1 to it. Writing a 0 to RDCOLERR has no effect.</p> <p>0 No collision error detected<br/>1 Collision error detected</p>   |
| 5<br>ACCERR     | <p>Flash Access Error Flag</p> <p>The ACCERR error bit indicates an illegal access has occurred to an FTFE resource caused by a violation of the command write sequence or issuing an illegal FTFE command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR bit has no effect.</p> <p>0 No access error detected<br/>1 Access error detected</p>   |
| 4<br>FPVIOL     | <p>Flash Protection Violation Flag</p> <p>The FPVIOL error bit indicates an attempt was made to program or erase an address in a protected area of program flash or data flash memory during a command write sequence or a write was attempted to a protected area of the FlexRAM while enabled for EEPROM. While FPVIOL is set, the CCIF flag cannot be cleared to launch a command. The FPVIOL bit is cleared by writing a 1 to FPVIOL while CCIF is set. Writing a 0 to the FPVIOL bit has no effect.</p> <p>0 No protection violation detected<br/>1 Protection violation detected</p>                       |
| 3-1<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 0<br>MGSTAT0    | <p>Memory Controller Command Completion Status Flag</p> <p>The MGSTAT0 status flag is set if an error is detected during execution of an FTFE command or during the flash reset sequence. As a status flag, this bit cannot (and need not) be cleared by the user like the other error flags in this register.</p> <p>The value of the MGSTAT0 bit for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the previous result is discarded and any previous error is cleared.</p> |

**30.34.2 Flash Configuration Register (FTFE\_FCENFG)**

This register provides information on the current functional state of the FTFE module.

The erase control bits (ERSAREQ and ERSSUSP) have write restrictions. SWAP, PFLSH, RAMRDY, and EEERDY are read-only status bits. The reset values for the SWAP, PFLSH, RAMRDY, and EEERDY bits are determined during the reset sequence.

Address: 4002\_0000h base + 1h offset = 4002\_0001h

|       |      |          |         |         |      |       |        |        |

| 1<br>RAMRDY | <p>RAM Ready</p> <p>This flag indicates the current status of the FlexRAM/programming acceleration RAM.</p> <p>For devices with FlexNVM: The state of the RAMRDY flag is normally controlled by the Set FlexRAM Function command. During the reset sequence, the RAMRDY flag is cleared if the FlexNVM block is partitioned for EEPROM and will be set if the FlexNVM block is not partitioned for EEPROM. The RAMRDY flag is cleared if the Program Partition command is run to partition the FlexNVM block for EEPROM. The RAMRDY flag sets after completion of the Erase All Blocks command or execution of the erase-all operation triggered external to the FTFE.</p> <p>For devices without FlexNVM: This bit should always be set.</p> <p>0 For devices with FlexNVM: FlexRAM is not available for traditional RAM access<br/>For devices without FlexNVM: Programming acceleration RAM is not available</p> <p>1 For devices with FlexNVM: FlexRAM is available as traditional RAM only; writes to the FlexRAM do not trigger EEPROM operations<br/>For devices without FlexNVM: Programming acceleration RAM is available</p> |
| 0<br>EEERDY | <p>For devices with FlexNVM: This flag indicates if the EEPROM backup data has been copied to the FlexRAM and is therefore available for read access.</p> <p>During the reset sequence, the EEERDY flag remains clear while CCIF=0 and only sets if the FlexNVM block is partitioned for EEPROM.</p> <p>For devices without FlexNVM: This bit is reserved and always has the value 0.</p> <p>0 For devices with FlexNVM: FlexRAM is not available for EEPROM operation<br/>For devices without FlexNVM: See RAMRDY for availability of programming acceleration RAM</p> <p>1 For devices with FlexNVM: FlexRAM is available for EEPROM operations where: <ul style="list-style-type: none"> <li>reads from the FlexRAM return data previously written to the FlexRAM in EEPROM mode and</li> <li>writes launch an EEPROM operation to store the written data in the FlexRAM and EEPROM backup</li> </ul> </p> <p>For devices without FlexNVM: Reserved</p>   |

### 30.34.3 Flash Security Register (FTFE\_FSEC)

This read-only register holds all bits associated with the security of the MCU and FTFE module.

During the reset sequence, the register is loaded with the contents of the flash security byte in the Flash Configuration Field located in program flash memory. The Flash basis for the values is signified by X in the reset value.

Address: 4002\_0000h base + 2h offset = 4002\_0002h

|       |       |    |      |    |        |    |     |    |
|-------|-------|----|------|----|--------|----|-----|----|
| Bit   | 7     | 6  | 5    | 4  | 3      | 2  | 1   | 0  |
| Read  | KEYEN |    | MEEN |    | FSLACC |    | SEC |    |
| Write |       |    |      |    |        |    |     |    |
| Reset | x*    | x* | x*   | x* | x*     | x* | x*  | x* |

- \* Notes:
- x = Undefined at reset.

**FTFE\_FSEC field descriptions**

| Field         | Description  |
|---------------|--|
| 7-6<br>KEYEN  | <p>Backdoor Key Security Enable</p> <p>These bits enable and disable backdoor key access to the FTFE module.</p> <p>00 Backdoor key access disabled<br/>           01 Backdoor key access disabled (preferred KEYEN state to disable backdoor key access)<br/>           10 Backdoor key access enabled<br/>           11 Backdoor key access disabled</p>   |
| 5-4<br>MEEN   | <p>Mass Erase Enable Bits</p> <p>Enables and disables mass erase capability of the FTFE module. The state of the MEEN bits is only relevant when the SEC bits are set to secure outside of NVM Normal Mode. When the SEC field is set to unsecure, the MEEN setting does not matter.</p> <p>00 Mass erase is enabled<br/>           01 Mass erase is enabled<br/>           10 Mass erase is disabled<br/>           11 Mass erase is enabled</p>  |
| 3-2<br>FSLACC | <p>Freescale Failure Analysis Access Code</p> <p>These bits enable or disable access to the flash memory contents during returned part failure analysis at Freescale. When SEC is secure and FSLACC is denied, access to the program flash contents is denied and any failure analysis performed by Freescale factory test must begin with a full erase to unsecure the part.</p> <p>When access is granted (SEC is unsecure, or SEC is secure and FSLACC is granted), Freescale factory testing has visibility of the current flash contents. The state of the FSLACC bits is only relevant when the SEC bits are set to secure. When the SEC field is set to unsecure, the FSLACC setting does not matter.</p> <p>00 Freescale factory access granted<br/>           01 Freescale factory access denied<br/>           10 Freescale factory access denied<br/>           11 Freescale factory access granted</p> |
| 1-0<br>SEC    | Flash Security   |

Table continues on the next page...

### FTFE\_FSEC field descriptions (continued)

| Field | Description   |
|-------|---|
|       | These bits define the security state of the MCU. In the secure state, the MCU limits access to FTFE module resources. The limitations are defined per device and are detailed in the Chip Configuration details. If the FTFE module is unsecured using backdoor key access, the SEC bits are forced to 10b. |
| 00    | MCU security status is secure   |
| 01    | MCU security status is secure   |
| 10    | MCU security status is unsecure (The standard shipping condition of the FTFE is unsecure.)  |
| 11    | MCU security status is secure   |

### 30.34.4 Flash Option Register (FTFE\_FOPT)

The flash option register allows the MCU to customize its operations by examining the state of these read-only bits, which are loaded from NVM at reset. The function of the bits is defined in the device's Chip Configuration details.

All bits in the register are read-only.

During the reset sequence, the register is loaded from the flash nonvolatile option byte in the Flash Configuration Field located in program flash memory. The flash basis for the values is signified by X in the reset value.

Address: 4002\_0000h base + 3h offset = 4002\_0003h

\* Notes:

- x = Undefined at reset.

### FTFE\_FOPT field descriptions

| Field      | Description  |
|------------|--|
| 7-0<br>OPT | Nonvolatile Option<br><br>These bits are loaded from flash to this register at reset. Refer to the device's Chip Configuration details for the definition and use of these bits. |

### 30.34.5 Flash Common Command Object Registers (FTFE\_FCCOBn)

The FCCOB register group provides 12 bytes for command codes and parameters. The individual bytes within the set append a 0-B hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOBB.

Address: 4002\_0000h base + 4h offset + (1d × i), where i=0d to 11d

**FTFE\_FCCOBn field descriptions**

| Field                     | Description  |                           |  |   |   |   |                       |   |                      |   |                     |   |             |   |             |   |             |   |             |   |             |   |             |
|---------------------------|--|---------------------------|--|---|---|---|-----------------------|---|----------------------|---|---------------------|---|-------------|---|-------------|---|-------------|---|-------------|---|-------------|---|-------------|
| 7-0<br>CCOBn              | <p>The FCCOB register provides a command code and relevant parameters to the memory controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command's execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes.</p> <p>Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1 by the memory controller.</p> <p>The following table shows a generic FTFE command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific FTFE command, typically an address and/or data values.</p> <p><b>NOTE:</b> The command parameter table is written in terms of FCCOB Number (which is equivalent to the byte number). This number is a reference to the FCCOB register name and is not the register address.</p> <table border="1"> <thead> <tr> <th>FCCOB Number<sup>1</sup></th> <th>Typical Command Parameter Contents [7:0]</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>FCMD (a code that defines the FTFE command)</td> </tr> <tr> <td>1</td> <td>Flash address [23:16]</td> </tr> <tr> <td>2</td> <td>Flash address [15:8]</td> </tr> <tr> <td>3</td> <td>Flash address [7:0]</td> </tr> <tr> <td>4</td> <td>Data Byte 0</td> </tr> <tr> <td>5</td> <td>Data Byte 1</td> </tr> <tr> <td>6</td> <td>Data Byte 2</td> </tr> <tr> <td>7</td> <td>Data Byte 3</td> </tr> <tr> <td>8</td> <td>Data Byte 4</td> </tr> <tr> <td>9</td> <td>Data Byte 5</td> </tr> </tbody> </table> | FCCOB Number <sup>1</sup> | Typical Command Parameter Contents [7:0] | 0 | FCMD (a code that defines the FTFE command) | 1 | Flash address [23:16] | 2 | Flash address [15:8] | 3 | Flash address [7:0] | 4 | Data Byte 0 | 5 | Data Byte 1 | 6 | Data Byte 2 | 7 | Data Byte 3 | 8 | Data Byte 4 | 9 | Data Byte 5 |

### FTFE\_FCCOB $n$ field descriptions (continued)

| Field  | Description               |  |
|--|---------------------------|--|
|  | FCCOB Number <sup>1</sup> | Typical Command Parameter Contents [7:0] |
|  | A                         | Data Byte 6                              |
|  | B                         | Data Byte 7                              |
| <p>1. Refers to FCCOB register name, not register address</p> <p><b>FCCOB Endianness and Multi-Byte Access:</b></p> <p>The FCCOB register group uses a big endian addressing convention. For all command parameter fields larger than 1 byte, the most significant data resides in the lowest FCCOB register number. The FCCOB register group may be read and written as individual bytes, aligned words (2 bytes) or aligned longwords (4 bytes).</p> |                           |  |

1. Refers to FCCOB register name, not register address

### 30.34.6 Program Flash Protection Registers (FTFE\_FPROT $n$ )

The FPROT registers define which program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any FTFE command. Unprotected regions can be changed by program and erase operations.

The four FPROT registers allow up to 32 protectable regions of equal memory size.

| Program flash protection register | Program flash protection bits |
|-----------------------------------|-------------------------------|
| FPROT0                            | PROT[31:24]                   |
| FPROT1                            | PROT[23:16]                   |
| FPROT2                            | PROT[15:8]                    |
| FPROT3                            | PROT[7:0]                     |

During the reset sequence, the FPROT registers are loaded with the contents of the program flash protection bytes in the Flash Configuration Field as indicated in the following table.

| Program flash protection register | Flash Configuration Field offset address |
|-----------------------------------|--|
| FPROT0                            | 0x000B                                   |
| FPROT1                            | 0x000A                                   |
| FPROT2                            | 0x0009                                   |
| FPROT3                            | 0x0008                                   |

To change the program flash protection that is loaded during the reset sequence, unprotect the sector of program flash memory that contains the Flash Configuration Field. Then, reprogram the program flash protection byte.

Address: 4002\_0000h base + 10h offset + (1d × i), where i=0d to 3d

- \* Notes:
- x = Undefined at reset.

**FTFE\_FPROTn field descriptions**

| Field       | Description   |

### 30.34.8 Data Flash Protection Register (FTFE\_FDPROT)

The FDPROT register defines which data flash regions are protected against program and erase operations. Protected Flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any FTFE command. Unprotected regions can be changed by both program and erase operations.

Address: 4002\_0000h base + 17h offset = 4002\_0017h

- \* Notes:
- x = Undefined at reset.

## 30.4 Functional Description

The following sections describe functional details of the FTFE module.

### 30.4.1 Program flash memory swap

The user can configure the memory map of the program flash space such that either half of the program flash memory can exist at relative address 0x0000. This swap feature enables the lower half of the program flash space to be operational while the upper half is being updated for future use.

The Swap Control command handles swapping the two halves of program flash memory within the memory map. See [Swap Control command \(program flash only devices\)](#) for details.

### 30.4.2 Flash Protection

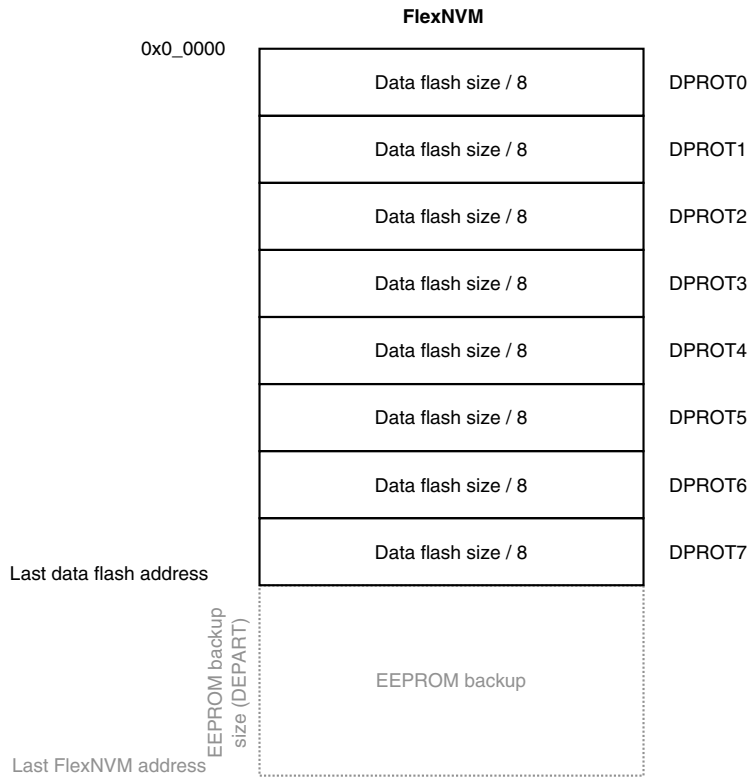

Individual regions within the flash memory can be protected from program and erase operations. Protection is controlled by the following registers:

- $FPROT_n$  — Four registers protect 32 regions of the program flash memory as shown in the following figure

**Figure 30-27. Program flash protection**

- FDPROT —
  - For  $2^n$  data flash sizes, protects eight regions of the data flash memory as shown in the following figure

**Figure 30-28. Data flash protection ( $2^n$  data flash sizes)**

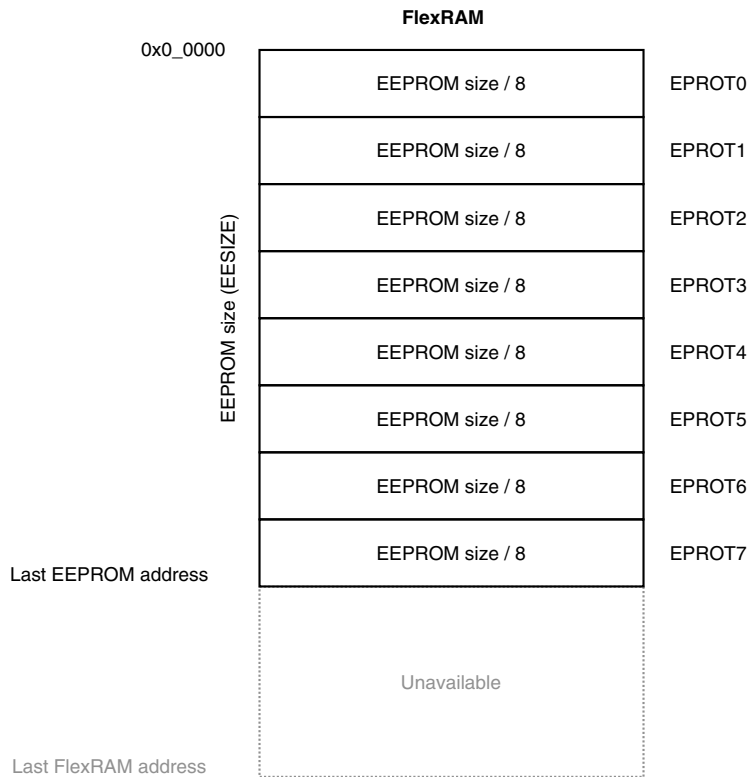

- For the non- $2^n$  data flash sizes, the protection granularity is 32KB. Therefore, for 192KB data flash size, only the DPROT[5:0] bits are used.

**Figure 30-29. Data flash protection (192KB data flash size)**

- FEPROT — Protects eight regions of the EEPROM memory as shown in the following figure

**Figure 30-30. EEPROM protection**

### 30.4.3 FlexNVM Description

This section describes the FlexNVM memory. This section does not apply for devices that contain only program flash memory.

#### 30.4.3.1 FlexNVM Block Partitioning for FlexRAM

The user can configure the FlexNVM block as either:

- Basic data flash,
- EEPROM flash records to support the built-in EEPROM feature, or
- A combination of both.

The user's FlexNVM configuration choice is specified using the Program Partition command described in [Program Partition command](#).

#### CAUTION

While different partitions of the FlexNVM block are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM partition code choices affect the endurance and data retention characteristics of the device.

#### 30.4.3.2 EEPROM User Perspective

The EEPROM system is shown in the following figure.

**Figure 30-31. Top Level EEPROM Architecture**

To handle varying customer requirements, the FlexRAM and FlexNVM blocks can be split into partitions as shown in the figure below.

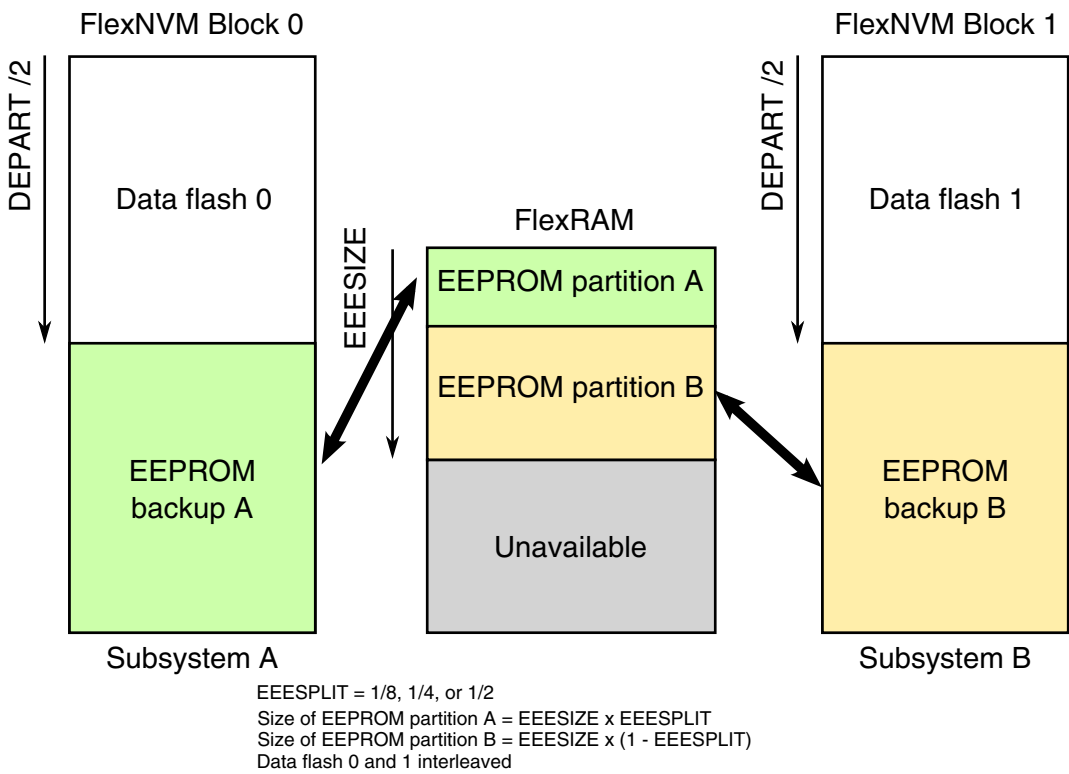

1. **EEPROM partition (EESIZE)** — The amount of FlexRAM used for EEPROM can be set from 0 Bytes (no EEPROM) to the maximum FlexRAM size (see [Table 30-2](#)). The remainder of the FlexRAM not used for EEPROM is not accessible while the FlexRAM is configured for EEPROM (see [Set FlexRAM Function command](#)).

The EEPROM partition grows upward from the bottom of the FlexRAM address space.

2. **Data flash partition (DEPART)** — The amount of FlexNVM memory used for data flash can be programmed from 0 bytes (all of the FlexNVM block is available for EEPROM backup) to the maximum size of the FlexNVM block (see [Table 30-4](#)).
3. **FlexNVM EEPROM partition** — The amount of FlexNVM memory used for EEPROM backup, which is equal to the FlexNVM block size minus the data flash memory partition size. The EEPROM backup size must be at least 16 times the EEPROM partition size in FlexRAM.
4. **EEPROM split factor (EEESPLIT)** — The FlexRAM partitioned for EEPROM can be divided into two subsystems, each backed by half of the partitioned EEPROM backup. One subsystem (A) is 1/8, 1/4, or 1/2 of the partitioned FlexRAM with the remainder belonging to the other subsystem (B).

The partition information (EEESIZE, DEPART, EEESPLIT) is stored in the data flash IFR and is programmed using the Program Partition command (see [Program Partition command](#)). Typically, the Program Partition command is executed only once in the lifetime of the device.

Data flash memory is useful for applications that need to quickly store large amounts of data or store data that is static. The EEPROM partition in FlexRAM is useful for storing smaller amounts of data that will be changed often. The EEPROM partition in FlexRAM can be further sub-divided to provide subsystems, each backed by the same amount of EEPROM backup with subsystem A having higher endurance if the split factor is 1/8 or 1/4.

**Figure 30-32. FlexRAM to FlexNVM Memory Mapping for EEPROM**

### 30.4.3.3 EEPROM implementation overview

Out of reset with the FSTAT[CCIF] bit clear, the partition settings (EEESIZE, DEPART, EEESPLIT) are read from the data flash IFR and the EEPROM file system is initialized accordingly. The EEPROM file system locates all valid EEPROM data records in EEPROM backup and copies the newest data to FlexRAM. The FSTAT[CCIF] and FCNFG[EEERDY] bits are set after data from all valid EEPROM data records is copied to the FlexRAM. After the CCIF bit is set, the FlexRAM is available for read or write access.

When configured for EEPROM use, writes to an unprotected location in FlexRAM invokes the EEPROM file system to program a new EEPROM data record in the EEPROM backup memory in a round-robin fashion. As needed, the EEPROM file system identifies the EEPROM backup sector that is being erased for future use and partially erases that EEPROM backup sector. After a write to the FlexRAM, the FlexRAM is not accessible until the FSTAT[CCIF] bit is set. The FCNFG[EEERDY] bit will also be set. If enabled, the interrupt associated with the FSTAT[CCIF] bit can be used to determine when the FlexRAM is available for read or write access.

After a sector in EEPROM backup is full of EEPROM data records, EEPROM data records from the sector holding the oldest data are gradually copied over to a previously-erased EEPROM backup sector. When the sector copy completes, the EEPROM backup sector holding the oldest data is tagged for erase.

### 30.4.3.4 Write endurance to FlexRAM for EEPROM

When the FlexNVM partition code is not set to full data flash, the EEPROM data set size can be set to any of several non-zero values.

The bytes not assigned to data flash via the FlexNVM partition code are used by the FTFE to obtain an effective endurance increase for the EEPROM data. The built-in EEPROM record management system raises the number of program/erase cycles that can be attained prior to device wear-out by cycling the EEPROM data through a larger EEPROM NVM storage space.

While different partitions of the FlexNVM are available, the intention is that a single choice for the FlexNVM partition code and EEPROM data set size is used throughout the entire lifetime of a given application. The EEPROM endurance equation and graph shown below assume that only one configuration is ever used.

$$\text{Writes\_subsystem} = \frac{\text{EEPROM} - 2 \times \text{EESPLIT} \times \text{EESIZE}}{\text{EESPLIT} \times \text{EESIZE}} \times \text{Write\_efficiency} \times n_{\text{nvmcycee}}$$

$$\text{Writes\_FlexRAM} = \frac{\text{EEPROM} - 2 \times \text{EESIZE}}{\text{EESIZE}} \times \text{Write\_efficiency} \times n_{\text{nvmcycee}}$$

where

- Writes\_FlexRAMsubsystem — minimum number of writes to each FlexRAM location for subsystem (each subsystem can have different endurance)
- EEPROM — allocated FlexNVM for each EEPROM subsystem based on DEPART; entered with the Program Partition command
- EESPLIT — FlexRAM split factor for subsystem; entered with the Program Partition command
- EESIZE — allocated FlexRAM based on DEPART; entered with the Program Partition command
- Write\_efficiency —
  - 0.25 for 8-bit writes to FlexRAM
  - 0.50 for 16-bit or 32-bit writes to FlexRAM
- $n_{\text{nvmcycee}}$  — EEPROM-backup cycling endurance

Figure 30-33. EEPROM backup writes to FlexRAM

### 30.4.4 Interrupts

The FTFE module can generate interrupt requests to the MCU upon the occurrence of various FTFE events. These interrupt events and their associated status and control bits are shown in the following table.

Table 30-30. FTFE Interrupt Sources

| FTFE Event                | Readable Status Bit | Interrupt Enable Bit |
|---------------------------|---------------------|----------------------|
| FTFE Command Complete     | FSTAT[CCIF]         | FCNFG[CCIE]          |
| FTFE Read Collision Error | FSTAT[RDCOLERR]     | FCNFG[RDCOLLIE]      |

**Note**

Vector addresses and their relative interrupt priority are determined at the MCU level.

## 30.4.5 Flash Operation in Low-Power Modes

### 30.4.5.1 Wait Mode

When the MCU enters wait mode, the FTFE module is not affected. The FTFE module can recover the MCU from wait via the command complete interrupt (see [Interrupts](#)).

### 30.4.5.2 Stop Mode

When the MCU requests stop mode, if an FTFE command is active (CCIF = 0) the command execution completes before the MCU is allowed to enter stop mode.

#### CAUTION

The MCU should never enter stop mode while any FTFE command is running (CCIF = 0).

#### NOTE

While the MCU is in very-low-power modes (VLPR, VLPW, VLPS), the FTFE module does not accept flash commands.

## 30.4.6 Functional modes of operation

The FTFE module has two operating modes: NVM Normal and NVM Special. The operating mode affects the command set availability (see [Table 30-31](#)). Refer to the Chip Configuration details of this device for how to activate each mode.

## 30.4.7 Flash memory reads and ignored writes

The FTFE module requires only the flash address to execute a flash memory read. MCU read access is available to all flash memory.

The MCU must not read from the flash memory while commands are running (as evidenced by CCIF=0) on that block. Read data cannot be guaranteed from a flash block while any command is processing within that block. The block arbitration logic detects any simultaneous access and reports this as a read collision error (see the FSTAT[RDCOLERR] bit).

### 30.4.8 Read while write (RWW)

The following simultaneous accesses are allowed for devices with FlexNVM:

- The user may read from the program flash memory while commands (typically program and erase operations) are active in the data flash and FlexRAM memory space.
- The user may read from one program flash memory block while commands are active in another program flash memory block.
- The MCU can fetch instructions from program flash during both data flash program and erase operations and while EEPROM-backup is maintained by the EEPROM commands.
- Conversely, the user may read from data flash and FlexRAM while program and erase commands are executing on the program flash.
- The user may also read from one data flash memory block while commands other than Program Partition are active in the other data flash memory block.
- When configured as traditional RAM, writes to the FlexRAM are allowed during data flash operations.

Simultaneous data flash operations and FlexRAM writes, when FlexRAM is used for EEE, are not possible.

The following simultaneous accesses are allowed for devices with program flash only:

- The user may read from one program flash memory block while commands are active in the other program flash memory block.

Simultaneous operations are further discussed in [Allowed simultaneous flash operations](#).

### 30.4.9 Flash Program and Erase

All flash functions except read require the user to setup and launch an FTFE command through a series of peripheral bus writes. The user cannot initiate any further FTFE commands until notified that the current command has completed. The FTFE command structure and operation are detailed in [FTFE Command Operations](#).

### 30.4.10 FTFE Command Operations

FTFE command operations are typically used to modify flash memory contents. The next sections describe:

## Functional Description

- The command write sequence used to set FTFE command parameters and launch execution
- A description of all FTFE commands available

### 30.4.10.1 Command Write Sequence

FTFE commands are specified using a command write sequence illustrated in [Figure 30-34](#). The FTFE module performs various checks on the command (FCCOB) content and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be zero and the CCIF flag must read 1 to verify that any previous command has completed. If CCIF is zero, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

Attempts to launch an FTFE command in VLP mode will be ignored.

#### 30.4.10.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the desired FTFE command. The individual registers that make up the FCCOB data set can be written in any order.

#### 30.4.10.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The CCIF flag remains zero until the FTFE command completes.

The FSTAT register contains a blocking mechanism, which prevents a new command from launching (can't clear CCIF) if the previous command resulted in an access error (FSTAT[ACCERR]=1) or a protection violation (FSTAT[FPVIOL]=1). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write clears the error flags, the second write clears CCIF.

#### 30.4.10.1.3 Command Execution and Error Reporting

The command processing has several steps:

1. The FTFE reads the command code and performs a series of parameter checks and protection checks, if applicable, which are unique to each command.

If the parameter check fails, the FSTAT[ACCERR] (access error) flag is set. ACCERR reports invalid instruction codes and out-of bounds addresses. Usually, access errors suggest that the command was not set-up with valid parameters in the FCCOB register group.

Program and erase commands also check the address to determine if the operation is requested to execute on protected areas. If the protection check fails, the FSTAT[FPVIOL] (protection error) flag is set.

Command processing never proceeds to execution when the parameter or protection step fails. Instead, command processing is terminated after setting the FSTAT[CCIF] bit.

2. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to erase verify, may occur during the execution phase. Run-time errors are reported in the FSTAT[MGSTAT0] bit. A command may have access errors, protection errors, and run-time errors, but the run-time errors are not seen until all access and protection errors have been corrected.
3. Command execution results, if applicable, are reported back to the user via the FCCOB and FSTAT registers.
4. The FTFE sets the FSTAT[CCIF] bit signifying that the command has completed.

The flow for a generic command write sequence is illustrated in the following figure.

Figure 30-34. Generic Flash Command Write Sequence Flowchart

### 30.4.10.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

| FCMD | Command         | Program flash 0 | Program flash 1 | Program flash 2<br>(Devices with only program flash) | Program flash 3<br>(Devices with only program flash) | Data flash 0-1<br>(Devices with FlexNVM) | FlexRAM<br>(Devices with FlexNVM) | Function   |
|------|-----------------|-----------------|-----------------|--|--|--|-----------------------------------|--|
| 0x00 | Read 1s Block   | x               | x               | x  | x  | x  |                                   | Verify that a program flash or data flash block is erased. FlexNVM block must not be partitioned for EEPROM. |
| 0x01 | Read 1s Section | x               | x               | x  | x  | x  |                                   | Verify that a given number of program flash or data flash locations from a starting address are erased.      |
| 0x02 | Program Check   | x               | x               | x  | x  | x  |                                   | Tests previously-programmed phrases at margin read levels.   |
| 0x03 | Read Resource   | IFR,ID          | IFR             | IFR  | IFR  | IFR                                      |                                   | Read 8 bytes from program flash IFR, data flash IFR, or version ID.  |
| 0x07 | Program Phrase  | x               | x               | x  | x  | x  |                                   | Program 8 bytes in a program flash block or a data flash block.  |

Table continues on the next page...

**Functional Description**

### 30.4.10.3 Flash commands by mode

The following table shows the flash commands that can be executed in each flash operating mode.

**Table 30-31. Flash commands by mode**

| FCMD | Command            | NVM Normal |        |         | NVM Special |        |         |
|------|--------------------|------------|--------|---------|-------------|--------|---------|
|      |                    | Unsecure   | Secure | MEEN=10 | Unsecure    | Secure | MEEN=10 |
| 0x00 | Read 1s Block      | ×          | ×      | ×       | ×           | —      | —       |
| 0x01 | Read 1s Section    | ×          | ×      | ×       | ×           | —      | —       |
| 0x02 | Program Check      | ×          | ×      | ×       | ×           | —      | —       |
| 0x03 | Read Resource      | ×          | ×      | ×       | ×           | —      | —       |
| 0x07 | Program Phrase     | ×          | ×      | ×       | ×           | —      | —       |
| 0x08 | Erase Flash Block  | ×          | ×      | ×       | ×           | —      | —       |
| 0x09 | Erase Flash Sector | ×          | ×      | ×       | ×           | —      | —       |
| 0x0B | Program Section    | ×          | ×      | ×       | ×           | —      | —       |
| 0x40 | Read 1s All Blocks | ×          | ×      | ×       | ×           | ×      | —       |
| 0x41 | Read Once          | ×          | ×      | ×       | ×           | —      | —       |
| 0x43 | Program Once       | ×          | ×      | ×       | ×           | —      | —       |
| 0x44 | Erase All Blocks   | ×          | ×      | ×       | ×           | ×      | —       |

*Table continues on the next page...*

**Table 30-31. Flash commands by mode (continued)**

| FCMD | Command                    | NVM Normal |        |         | NVM Special |        |         |
|------|----------------------------|------------|--------|---------|-------------|--------|---------|
|      |                            | Unsecure   | Secure | MEEN=10 | Unsecure    | Secure | MEEN=10 |
| 0x45 | Verify Backdoor Access Key | x          | x      | x       | x           | —      | —       |
| 0x46 | Swap Control               | x          | x      | x       | x           | —      | —       |
| 0x80 | Program Partition          | x          | x      | x       | x           | —      | —       |
| 0x81 | Set FlexRAM Function       | x          | x      | x       | x           | —      | —       |

### 30.4.10.4 Allowed simultaneous flash operations

Only the operations marked 'OK' in the following table are permitted to run simultaneously on the program flash, data flash, and FlexRAM memories. Some operations cannot be executed simultaneously because certain hardware resources are shared by the memories. The priority has been placed on permitting program flash reads while program and erase operations execute on the FlexNVM and FlexRAM. This provides read (program flash) while write (FlexNVM, FlexRAM) functionality.

For devices containing FlexNVM:

**Table 30-32. Allowed Simultaneous Memory Operations**

|                              |                                 | Program flash X <sup>1</sup> |                |                                 | Data flash 0/1 |                |                                 | FlexRAM |                      |                      |
|------------------------------|---------------------------------|------------------------------|----------------|---------------------------------|----------------|----------------|---------------------------------|---------|----------------------|----------------------|
|                              |                                 | Read                         | Program Phrase | Erase Flash Sector <sup>2</sup> | Read           | Program Phrase | Erase Flash Sector <sup>2</sup> | Read    | E-Write <sup>3</sup> | R-Write <sup>4</sup> |
| Program flash Y <sup>1</sup> | Read                            |                              | OK             | OK                              |                | OK             | OK                              |         | OK                   |                      |
|                              | Program Phrase                  | OK                           |                |                                 | OK             |                |                                 | OK      |                      | OK                   |
|                              | Erase Flash Sector <sup>2</sup> | OK                           |                |                                 | OK             |                |                                 | OK      |                      | OK                   |
| Data flash 1/0               | Read                            |                              | OK             | OK                              |                | OK             | OK                              |         |                      |                      |
|                              | Program Phrase                  | OK                           |                |                                 | OK             |                |                                 | OK      |                      | OK                   |
|                              | Erase Flash Sector <sup>2</sup> | OK                           |                |                                 | OK             |                |                                 | OK      |                      | OK                   |
| FlexRAM                      | Read                            |                              | OK             | OK                              |                | OK             | OK                              |         |                      |                      |
|                              | E-Write <sup>3</sup>            | OK                           |                |                                 |                |                |                                 |         |                      |                      |
|                              | R-Write <sup>4</sup>            |                              | OK             | OK                              |                | OK             | OK                              |         |                      |                      |

1. P-Flash X refers to any of the P-Flash blocks (0, 1) and P-Flash Y refers to any of the P-Flash blocks (0, 1), but not the same block. Thus, it is possible to read from any of the blocks while programming or erasing another.
2. Also applies to Erase Flash Block

- 3. When FlexRAM configured for EEPROM (EEERDY=1).
- 4. When FlexRAM configured as traditional RAM (RAMRDY=1); single cycle operation.

For devices containing program flash only:

**Table 30-33. Allowed Simultaneous Memory Operations**

|                              |                    | Program flash X <sup>1</sup> |                |                    |                   |
|------------------------------|--------------------|------------------------------|----------------|--------------------|-------------------|
|                              |                    | Read                         | Program Phrase | Erase Flash Sector | Erase Flash Block |
| Program flash Y <sup>1</sup> | Read               |                              | OK             | OK                 | OK                |
|                              | Program Phrase     | OK                           |                |                    |                   |
|                              | Erase Flash Sector | OK                           |                |                    |                   |
|                              | Erase Flash Block  | OK                           |                |                    |                   |

1. P-Flash X refers to any of the P-Flash blocks (0, 1, 2, 3) and P-Flash Y refers to any of the P-Flash blocks (0, 1, 2, 3), but not the same block. Thus, it is possible to read from any of the blocks while programming or erasing another.

### 30.4.11 Margin Read Commands

The Read-1s commands (Read 1s All Blocks, Read 1s Block, and Read 1s Section) and the Program Check command have a margin choice parameter that allows the user to apply non-standard read reference levels to the program flash and data flash array reads performed by these commands. Using the preset 'user' and 'factory' margin levels, these commands perform their associated read operations at tighter tolerances than a 'normal' read. These non-standard read levels are applied only during the command execution. All simple (uncommanded) flash array reads to the MCU always use the standard, un-margined, read reference level.

Only the 'normal' read level should be employed during normal flash usage. The non-standard, 'user' and 'factory' margin levels should be employed only in special cases. They can be used during special diagnostic routines to gain confidence that the device is not suffering from the end-of-life data loss customary of flash memory devices.

Erased ('1') and programmed ('0') bit states can degrade due to elapsed time and data cycling (number of times a bit is erased and re-programmed). The lifetime of the erased states is relative to the last erase operation. The lifetime of the programmed states is measured from the last program time.

The 'user' and 'factory' levels become, in effect, a minimum safety margin; i.e. if the reads pass at the tighter tolerances of the 'user' and 'factory' margins, then the 'normal' reads have at least this much safety margin before they experience data loss.

The 'user' margin is a small delta to the normal read reference level. 'User' margin levels can be employed to check that flash memory contents have adequate margin for normal level read operations. If unexpected read results are encountered when checking flash memory contents at the 'user' margin levels, loss of information might soon occur during 'normal' readout.

The 'factory' margin is a bigger deviation from the norm, a more stringent read criteria that should only be attempted immediately (or very soon) after completion of an erase or program command, early in the cycling life. 'Factory' margin levels can be used to check that flash memory contents have adequate margin for long-term data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at 'factory' margin levels, the flash memory contents should be erased and reprogrammed.

### CAUTION

Factory margin levels must only be used during verify of the initial factory programming.

## 30.4.12 Flash command descriptions

This section describes all flash commands that can be launched by a command write sequence. The FTFE sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in a FCCOB field for the specific commands. Refer to the error handling table provided for each command.

Ensure that the ACCERR and FPVIOL bits in the FSTAT register are cleared prior to starting the command write sequence. As described in [Launch the Command by Clearing CCIF](#), a new command cannot be launched while these error flags are set.

Do not attempt to read a flash block while the FTFE is running a command (CCIF = 0) on that same block. The FTFE may return invalid data to the MCU with the collision error flag (FSTAT[RDCOLERR]) set.

When required by the command, address bit 23 selects between program flash memory (=0) and data flash memory (=1).

## CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

### 30.4.12.1 Read 1s Block command

The Read 1s Block command checks to see if an entire program flash or data flash block has been erased to the specified margin level. The FCCOB flash address bits determine which block is erase-verified.

**Table 30-34. Read 1s Block Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]   |
|--------------|--|
| 0            | 0x00 (RD1BLK)  |
| 1            | Flash address [23:16] in the flash block to be verified            |
| 2            | Flash address [15:8] in the flash block to be verified             |
| 3            | Flash address [7:0] <sup>1</sup> in the flash block to be verified |
| 4            | Read-1 Margin Choice   |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Read 1s Block command, the FTFE sets the read margin for 1s according to [Table 30-35](#) and then reads all locations within the selected program flash or data flash block.

When the data flash is targeted, DEPART must be set for no EEPROM, else the Read 1s Block command aborts setting the FSTAT[ACCERR] bit. If the FTFE fails to read all 1s (i.e. the flash block is not fully erased), the FSTAT[MGSTAT0] bit is set. The CCIF flag sets after the Read 1s Block operation has completed.

**Table 30-35. Margin Level Choices for Read 1s Block**

| Read Margin Choice | Margin Level Description                              |
|--------------------|---|
| 0x00               | Use the 'normal' read level for 1s                    |
| 0x01               | Apply the 'User' margin to the normal read-1 level    |
| 0x02               | Apply the 'Factory' margin to the normal read-1 level |

**Table 30-36. Read 1s Block Command Error Handling**

| Error Condition                                | Error Bit     |
|--|---------------|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid margin choice is specified          | FSTAT[ACCERR] |

*Table continues on the next page...*

**Table 30-36. Read 1s Block Command Error Handling (continued)**

| Error Condition   | Error Bit      |
|---|----------------|
| Program flash is selected and the address is out of program flash range | FSTAT[ACCERR]  |
| Data flash is selected and the address is out of data flash range       | FSTAT[ACCERR]  |
| Data flash is selected with EEPROM enabled                              | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned                                    | FSTAT[ACCERR]  |
| Read-1s fails   | FSTAT[MGSTAT0] |

### 30.4.12.2 Read 1s Section command

The Read 1s Section command checks if a section of program flash or data flash memory is erased to the specified read margin level. The Read 1s Section command defines the starting address and the number of double-phrases to be verified.

**Table 30-37. Read 1s Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]   |
|--------------|--|
| 0            | 0x01 (RD1SEC)  |
| 1            | Flash address [23:16] of the first double-phrase to be verified            |
| 2            | Flash address [15:8] of the first double-phrase to be verified             |
| 3            | Flash address [7:0] <sup>1</sup> of the first double-phrase to be verified |
| 4            | Number of doublephrases to be verified [15:8]                              |
| 5            | Number of doublephrases to be verified [7:0]                               |
| 6            | Read-1 Margin Choice   |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Read 1s Section command, the FTFE sets the read margin for 1s according to [Table 30-38](#) and then reads all locations within the specified section of flash memory.

If the FTFE fails to read all 1s (i.e. the flash section is not erased), the FSTAT(MGSTAT0) bit is set. The CCIF flag sets after the Read 1s Section operation completes.

**Table 30-38. Margin Level Choices for Read 1s Section**

| Read Margin Choice | Margin Level Description                              |
|--------------------|---|
| 0x00               | Use the 'normal' read level for 1s                    |
| 0x01               | Apply the 'User' margin to the normal read-1 level    |
| 0x02               | Apply the 'Factory' margin to the normal read-1 level |

**Table 30-39. Read 1s Section Command Error Handling**

| Error Condition                                      | Error Bit      |
|--|----------------|
| Command not available in current mode/security       | FSTAT[ACCERR]  |
| An invalid margin code is supplied                   | FSTAT[ACCERR]  |
| An invalid flash address is supplied                 | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned                 | FSTAT[ACCERR]  |
| The requested section crosses a flash block boundary | FSTAT[ACCERR]  |
| The requested number of double-phrases is zero       | FSTAT[ACCERR]  |
| Read-1s fails  | FSTAT[MGSTAT0] |

### 30.4.12.3 Program Check command

The Program Check command tests a previously programmed program flash or data flash longword to see if it reads correctly at the specified margin level.

**Table 30-40. Program Check Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]             |
|--------------|----------------------------------|
| 0            | 0x02 (PGMCHK)                    |
| 1            | Flash address [23:16]            |
| 2            | Flash address [15:8]             |
| 3            | Flash address [7:0] <sup>1</sup> |
| 4            | Margin Choice                    |
| 8            | Byte 0 expected data             |
| 9            | Byte 1 expected data             |
| A            | Byte 2 expected data             |
| B            | Byte 3 expected data             |

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Check command, the FTFE sets the read margin for 1s based on the provided margin choice according to [Table 30-41](#). The Program Check operation then reads the specified longword, and compares the actual read data to the expected data provided by the FCCOB. If the comparison at margin-1 fails, the MGSTAT0 bit is set.

The FTFE will then set the read margin for 0s based on the provided margin choice. The Program Check operation will then read the specified longword and compare the actual read data to the expected data provided by the FCCOB. If the comparison at margin-0 fails, the MGSTAT0 bit will be set. The CCIF flag will set after the Program Check operation has completed.

## Functional Description

The starting address must be longword aligned (the lowest two bits of the byte address must be 00):

- Byte 0 data is expected at the supplied 32-bit aligned address,
- Byte 1 data is expected at byte address specified + 0b01,
- Byte 2 data is expected at byte address specified + 0b10, and
- Byte 3 data is expected at byte address specified + 0b11.

### NOTE

See the description of margin reads, [Margin Read Commands](#)

**Table 30-41. Margin Level Choices for Program Check**

| Read Margin Choice | Margin Level Description                          |
|--------------------|---|
| 0x01               | Read at 'User' margin-1 and 'User' margin-0       |
| 0x02               | Read at 'Factory' margin-1 and 'Factory' margin-0 |

**Table 30-42. Program Check Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security              | FSTAT[ACCERR]  |
| An invalid flash address is supplied                        | FSTAT[ACCERR]  |
| Flash address is not longword aligned                       | FSTAT[ACCERR]  |
| An invalid margin choice is supplied                        | FSTAT[ACCERR]  |
| Either of the margin reads does not match the expected data | FSTAT[MGSTAT0] |

## 30.4.12.4 Read Resource Command

The Read Resource command is provided for the user to read data from special-purpose memory resources located within the Flash module. The special-purpose memory resources available include program flash IFR, data flash IFR space, and the Version ID field. The Version ID field contains an 8 byte code that indicates a specific FTFE implementation.

**Table 30-43. Read Resource Command FCCOB Requirements**

| FCCOB Number    | FCCOB contents [7:0]                                    |
|-----------------|---|
| 0               | 0x03 (RDRSRC)   |
| 1               | Flash address [23:16]                                   |
| 2               | Flash address [15:8]                                    |
| 3               | Flash address [7:0] <sup>1</sup>                        |
| 4               | Resource select code (see <a href="#">Table 30-44</a> ) |
| Returned values |   |

*Table continues on the next page...*

**Table 30-43. Read Resource Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB contents [7:0] |
|--------------|----------------------|
| 4            | Read Data [64:56]    |
| 5            | Read Data [55:48]    |
| 6            | Read Data [47:40]    |
| 7            | Read Data [39:32]    |
| 8            | Read Data [31:24]    |
| 9            | Read Data [23:16]    |
| A            | Read Data [15:8]     |
| B            | Read Data [7:0]      |

1. Must be 64-bit aligned (Flash address [2:0] = 000).

**Table 30-44. Read Resource Select Codes**

| Resource Select Code | Description            | Resource Size | Local Address Range   |
|----------------------|------------------------|---------------|-----------------------|
| 0x00                 | Program Flash 0 IFR    | 1024 Bytes    | 0x00_0000 - 0x00_03FF |
| 0x00                 | Program Flash Swap IFR | 1024 Bytes    | 0x02_0000 - 0x02_03FF |
| 0x00                 | Data Flash 0 IFR       | 1024 Bytes    | 0x80_0000 - 0x80_03FF |
| 0x01                 | Version ID             | 8 Bytes       | 0x00_0008 - 0x00_000F |

After clearing CCIF to launch the Read Resource command, eight consecutive bytes are read from the selected resource at the provided relative address and stored in the FCCOB register. The CCIF flag will set after the Read Resource operation has completed. The Read Resource command exits with an access error if an invalid resource code is provided or if the address for the applicable area is out-of-range.

**Table 30-45. Read Resource Command Error Handling**

| Error Condition  | Error Bit     |
|--|---------------|
| Command not available in current mode/security           | FSTAT[ACCERR] |
| An invalid resource code is entered                      | FSTAT[ACCERR] |
| Flash address is out-of-range for the targeted resource. | FSTAT[ACCERR] |
| Flash address is not 64-bit aligned                      | FSTAT[ACCERR] |

### 30.4.12.5 Program Phrase command

The Program Phrase command programs eight previously-erased bytes in the program flash memory or in the data flash memory using an embedded algorithm.

## CAUTION

A Flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a Flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 30-46. Program Phrase Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]             |
|--------------|----------------------------------|
| 0            | 0x07 (PGM8)                      |
| 1            | Flash address [23:16]            |
| 2            | Flash address [15:8]             |
| 3            | Flash address [7:0] <sup>1</sup> |
| 4            | Byte 0 program value             |
| 5            | Byte 1 program value             |
| 6            | Byte 2 program value             |
| 7            | Byte 3 program value             |
| 8            | Byte 4 program value             |
| 9            | Byte 5 program value             |
| A            | Byte 6 program value             |
| B            | Byte 7 program value             |

1. Must be 64-bit aligned (Flash address [2:0] = 000)

Upon clearing CCIF to launch the Program Phrase command, the FTFE programs the data bytes into the flash using the supplied address. The protection status is always checked. If the swap system is enabled, the double-phrase containing the swap indicator address in each half of the program flash space is implicitly protected from programming. The targeted flash locations must be currently unprotected (see the description of the FPROT registers) to permit execution of the Program Phrase operation.

The programming operation is unidirectional. It can only move NVM bits from the erased state ('1') to the programmed state ('0'). Erased bits that fail to program to the '0' state are flagged as errors in MGSTAT0. The CCIF flag is set after the Program Phrase operation completes.

The starting address must be 64-bit aligned (flash address [2:0] = 000):

- Byte 0 data is written to the starting address ('start'),
- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10, and
- Byte 3 data is programmed to byte address start+0b11, etc.

**Table 30-47. Program Phrase Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security                | FSTAT[ACCERR]  |
| An invalid flash address is supplied                          | FSTAT[ACCERR]  |
| Flash address is not 64-bit aligned                           | FSTAT[ACCERR]  |
| Flash address points to a protected area                      | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation. | FSTAT[MGSTAT0] |

### 30.4.12.6 Erase Flash Block Command

The Erase Flash Block operation erases all addresses in a single program flash or data flash block.

**Table 30-48. Erase Flash Block Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]   |
|--------------|--|
| 0            | 0x08 (ERSBLK)  |
| 1            | Flash address [23:16] in the flash block to be erased            |
| 2            | Flash address [15:8] in the flash block to be erased             |
| 3            | Flash address [7:0] <sup>1</sup> in the flash block to be erased |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Erase Flash Block command, the FTFE erases the main array of the selected flash block and verifies that it is erased. When the data flash is targeted, DEPART must be set for no EEPROM (see [Table 30-4](#)) else the Erase Flash Block command aborts setting the FSTAT[ACCERR] bit. The Erase Flash Block command aborts and sets the FSTAT[FPVIOL] bit if any region within the block is protected (see the description of the program flash protection (FPROT) registers and the data flash protection (FDPROT) registers). If the swap system is enabled, the swap indicator address is implicitly protected from block erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the program flash block being erased is the non-active block that contains the swap indicator address. If the erase verify fails, the MGSTAT0 bit in FSTAT is set. The CCIF flag will set after the Erase Flash Block operation has completed.

**Table 30-49. Erase Flash Block Command Error Handling**

| Error Condition   | Error Bit     |
|---|---------------|
| Command not available in current mode/security                          | FSTAT[ACCERR] |
| Program flash is selected and the address is out of program flash range | FSTAT[ACCERR] |
| Data flash is selected and the address is out of data flash range       | FSTAT[ACCERR] |

*Table continues on the next page...*

**Table 30-49. Erase Flash Block Command Error Handling (continued)**

| Error Condition   | Error Bit      |
|---|----------------|
| Data flash is selected with EEPROM enabled                                | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned                                      | FSTAT[ACCERR]  |
| Any area of the selected flash block is protected                         | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation <sup>1</sup> | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s Block command to verify all bits are erased.

### 30.4.12.7 Erase Flash Sector command

The Erase Flash Sector operation erases all addresses in a flash sector.

**Table 30-50. Erase Flash Sector Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]  |
|--------------|---|
| 0            | 0x09 (ERSSCR)   |
| 1            | Flash address [23:16] in the flash sector to be erased            |
| 2            | Flash address [15:8] in the flash sector to be erased             |
| 3            | Flash address [7:0] <sup>1</sup> in the flash sector to be erased |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Erase Flash Sector command, the FTFE erases the selected program flash or data flash sector and then verifies that it is erased. The Erase Flash Sector command aborts if the selected sector is protected (see the description of the FPROT registers). If the swap system is enabled, the swap indicator address in each program flash block is implicitly protected from sector erase unless the swap system is in the UPDATE or UPDATE-ERASED state and the program flash sector containing the swap indicator address being erased is in the non-active block. If the erase-verify fails the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase Flash Sector operation completes. The Erase Flash Sector command is suspendable (see the FCNFG[ERSSUSP] bit and [Figure 30-35](#)).

**Table 30-51. Erase Flash Sector Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security                            | FSTAT[ACCERR]  |
| An invalid Flash address is supplied                                      | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned                                      | FSTAT[ACCERR]  |
| The selected program flash or data flash sector is protected              | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation <sup>1</sup> | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s Section command to verify all bits are erased.

### 30.4.12.7.1 Suspending an Erase Flash Sector Operation

To suspend an Erase Flash Sector operation set the FCNFG[ERSSUSP] bit (see [Flash configuration field description](#)) when CCIF is clear and the CCOB command field holds the code for the Erase Flash Sector command. During the Erase Flash Sector operation (see [Erase Flash Sector command](#)), the flash samples the state of the ERSSUSP bit at convenient points. If the FTFE detects that the ERSSUSP bit is set, the Erase Flash Sector operation is suspended and the FTFE sets CCIF. While ERSSUSP is set, all writes to flash registers are ignored except for writes to the FSTAT and FCNFG registers.

If an Erase Flash Sector operation effectively completes before the FTFE detects that a suspend request has been made, the FTFE clears the ERSSUSP bit prior to setting CCIF. When an Erase Flash Sector operation has been successfully suspended, the FTFE sets CCIF and leaves the ERSSUSP bit set. While CCIF is set, the ERSSUSP bit can only be cleared to prevent the withdrawal of a suspend request before the FTFE has acknowledged it.

### 30.4.12.7.2 Resuming a Suspended Erase Flash Sector Operation

If the ERSSUSP bit is still set when CCIF is cleared to launch the next command, the previous Erase Flash Sector operation resumes. The FTFE acknowledges the request to resume a suspended operation by clearing the ERSSUSP bit. A new suspend request can then be made by setting ERSSUSP. A single Erase Flash Sector operation can be suspended and resumed multiple times.

There is a minimum elapsed time limit between the request to resume the Erase Flash Sector operation (CCIF is cleared) and the request to suspend the operation again (ERSSUSP is set). This minimum time period is required to ensure that the Erase Flash Sector operation will eventually complete. If the minimum period is continually violated, i.e. the suspend requests come repeatedly and too quickly, no forward progress is made by the Erase Flash Sector algorithm. The resume/suspend sequence runs indefinitely without completing the erase.

### 30.4.12.7.3 Aborting a Suspended Erase Flash Sector Operation

The user may choose to abort a suspended Erase Flash Sector operation by clearing the ERSSUSP bit prior to clearing CCIF for the next command launch. When a suspended operation is aborted, the FTFE starts the new command using the new FCCOB contents.

While FCNFG[ERSSUSP] is set, a write to the FlexRAM while FCNFG[EEERDY] is set clears ERSSUSP and aborts the suspended operation. The FlexRAM write operation is executed by the FTFE.

### Note

Aborting the erase leaves the bitcells in an indeterminate, partially-erased state. Data in this sector is not reliable until a new erase command fully completes.

The following figure shows how to suspend and resume the Erase Flash Sector operation.

**Figure 30-35. Suspend and Resume of Erase Flash Sector Operation**

### 30.4.12.8 Program Section command

The Program Section operation programs the data found in the section program buffer to previously erased locations in the flash memory using an embedded algorithm. Data is preloaded into the section program buffer by writing to the FlexRAM while it is set to function as a programming acceleration RAM (see [Flash sector programming](#)).

The section program buffer is limited to the lower quarter of the programming acceleration RAM (byte addresses 0x0000-0x0FFF). Data written to the remainder of the programming acceleration RAM is ignored and may be overwritten during Program Section command execution.

#### CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 30-52. Program Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                       |
|--------------|--|
| 0            | 0x0B (PGMSEC)                              |
| 1            | Flash address [23:16]                      |
| 2            | Flash address [15:8]                       |
| 3            | Flash address [7:0] <sup>1</sup>           |
| 4            | Number of double-phrases to program [15:8] |
| 5            | Number of double-phrases to program [7:0]  |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

After clearing CCIF to launch the Program Section command, the FTFE will block access to the programming acceleration RAM (program flash only devices) or FlexRAM (FlexNVM devices) and program the data residing in the Section Program Buffer into the flash memory starting at the flash address provided.

The starting address must be unprotected (see the description of the FPROT registers) to permit execution of the Program Section operation. If the swap system is enabled, the double-phrase containing the swap indicator address in each half of the program flash space is implicitly protected from programming. If the double-phrase containing the swap indicator address is encountered during the Program Section operation, it will be bypassed without setting FPVIOL and the contents will not be programmed. Programming, which is not allowed to cross a flash sector boundary, continues until all requested double-phrases have been programmed.

After the Program Section operation has completed, the CCIF flag will set and normal access to the FlexRAM is restored. The contents of the Section Program Buffer is not changed by the Program Section operation.

**Table 30-53. Program Section Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security  | FSTAT[ACCERR]  |
| An invalid flash address is supplied  | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned  | FSTAT[ACCERR]  |
| The requested section crosses a program flash sector boundary   | FSTAT[ACCERR]  |
| The requested number of double-phrases is zero  | FSTAT[ACCERR]  |
| The space required to store data for the requested number of double-phrases is more than one quarter the size of the programming acceleration RAM (program flash only devices) or FlexRAM (FlexNVM devices) | FSTAT[ACCERR]  |
| The FlexRAM is not set to function as a traditional RAM, i.e. set if RAMRDY=0   | FSTAT[ACCERR]  |
| The flash address falls in a protected area   | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation  | FSTAT[MGSTAT0] |

### 30.4.12.8.1 Flash sector programming

The process of programming an entire flash sector using the Program Section command is as follows:

1. If required, execute the Set FlexRAM Function command to make the FlexRAM available as traditional RAM and initialize the FlexRAM to all ones.
2. Launch the Erase Flash Sector command to erase the flash sector to be programmed.
3. Beginning with the starting address of the programming acceleration RAM (program flash only devices) or FlexRAM (FlexNVM devices), sequentially write enough data to the RAM to fill an entire flash sector. This area of the RAM serves as the section program buffer.

#### NOTE

In step 1, the section program buffer was initialized to all ones, the erased state of the flash memory.

The section program buffer can be written to while the operation launched in step 2 is executing, i.e. while CCIF = 0.

4. Execute the Program Section command to program the contents of the section program buffer into the selected flash sector.
5. To program additional flash sectors, repeat steps 2 through 4.
6. To restore EEPROM functionality, execute the Set FlexRAM Function command to make the FlexRAM available for EEPROM.

### 30.4.12.9 Read 1s All Blocks Command

The Read 1s All Blocks command checks if the program flash blocks, data flash blocks, EEPROM backup records, and data flash IFR have been erased to the specified read margin level, if applicable, and releases security if the readout passes, i.e. all data reads as '1'.

**Table 30-54. Read 1s All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 0            | 0x40 (RD1ALL)        |
| 1            | Read-1 Margin Choice |

After clearing CCIF to launch the Read 1s All Blocks command, the FTFE :

- sets the read margin for 1s according to [Table 30-55](#),
- checks the contents of the program flash, data flash, EEPROM backup records, and data flash IFR are in the erased state.

If the FTFE confirms that these memory resources are erased, security is released by setting the FSEC[SEC] field to the unsecure state. The security byte in the flash configuration field (see [Flash configuration field description](#)) remains unaffected by the Read 1s All Blocks command. If the read fails, i.e. all flash memory resources are not in the fully erased state, the FSTAT[MGSTAT0] bit is set.

The EEERDY and RAMRDY bits are clear during the Read 1s All Blocks operation and are restored at the end of the Read 1s All Blocks operation.

The CCIF flag sets after the Read 1s All Blocks operation has completed.

**Table 30-55. Margin Level Choices for Read 1s All Blocks**

| Read Margin Choice | Margin Level Description                              |
|--------------------|---|
| 0x00               | Use the 'normal' read level for 1s                    |
| 0x01               | Apply the 'User' margin to the normal read-1 level    |
| 0x02               | Apply the 'Factory' margin to the normal read-1 level |

**Table 30-56. Read 1s All Blocks Command Error Handling**

| Error Condition                       | Error Bit      |
|---------------------------------------|----------------|
| An invalid margin choice is specified | FSTAT[ACCERR]  |
| Read-1s fails                         | FSTAT[MGSTAT0] |

### 30.4.12.10 Read Once Command

The Read Once command provides read access to a reserved 64-byte field located in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 8 records, each 8 bytes long. The Program Once field is programmed using the Program Once command described in [Program Once command](#).

**Table 30-57. Read Once Command FCCOB Requirements**

| FCCOB Number    | FCCOB Contents [7:0]                    |
|-----------------|---|
| 0               | 0x41 (RDONCE)                           |
| 1               | Program Once record index (0x00 - 0x07) |
| Returned Values |   |
| 4               | Program Once byte 0 value               |
| 5               | Program Once byte 1 value               |
| 6               | Program Once byte 2 value               |
| 7               | Program Once byte 3 value               |
| 8               | Program Once byte 4 value               |
| 9               | Program Once byte 5 value               |
| A               | Program Once byte 6 value               |
| B               | Program Once byte 7 value               |

After clearing CCIF to launch the Read Once command, an 8-byte Program Once record is read from the program flash IFR and stored in the FCCOB register. The CCIF flag is set after the Read Once operation completes. Valid record index values for the Read Once command range from 0x00 to 0x07. During execution of the Read Once command, any attempt to read addresses within the program flash block containing this 64-byte field returns invalid data. The Read Once command can be executed any number of times.

**Table 30-58. Read Once Command Error Handling**

| Error Condition                                | Error Bit     |
|--|---------------|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid record index is supplied            | FSTAT[ACCERR] |

### 30.4.12.11 Program Once command

The Program Once command enables programming to a reserved 64-byte field in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 8 records, each 8 bytes long. The Program Once field can

be read using the Read Once command (see [Read Once Command](#)) or using the Read Resource command (see [Read Resource Command](#)). Each Program Once record can be programmed only once since the program flash 0 IFR cannot be erased.

**Table 30-59. Program Once Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                    |
|--------------|---|
| 0            | 0x43 (PGMONCE)                          |
| 1            | Program Once record index (0x00 - 0x07) |
| 2            | Not Used                                |
| 3            | Not Used                                |
| 4            | Program Once Byte 0 value               |
| 5            | Program Once Byte 1 value               |
| 6            | Program Once Byte 2 value               |
| 7            | Program Once Byte 3 value               |
| 8            | Program Once Byte 4 value               |
| 9            | Program Once Byte 5 value               |
| A            | Program Once Byte 6 value               |
| B            | Program Once Byte 7 value               |

After clearing CCIF to launch the Program Once command, the FTFE first verifies that the selected record is erased. If erased, then the selected record is programmed using the values provided. The Program Once command also verifies that the programmed values read back correctly. The CCIF flag is set after the Program Once operation has completed.

The reserved program flash 0 IFR location accessed by the Program Once command cannot be erased and any attempt to program one of these records when the existing value is not Fs (erased) is not allowed. Valid record index values for the Program Once command range from 0x00 to 0x07. During execution of the Program Once command, any attempt to read addresses within program flash 0 returns invalid data.

**Table 30-60. Program Once Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security                                      | FSTAT[ACCERR]  |
| An invalid record index is supplied   | FSTAT[ACCERR]  |
| The requested record has already been programmed to a non-erased value <sup>1</sup> | FSTAT[ACCERR]  |
| Any errors have been encountered during the verify operation.                       | FSTAT[MGSTAT0] |

1. If a Program Once record is initially programmed to 0xFFFF\_FFFF\_FFFF\_FFFF, the Program Once command is allowed to execute again on that same record.

### 30.4.12.12 Erase All Blocks Command

The Erase All Blocks operation erases all flash memory, initializes the FlexRAM, verifies all memory contents, and releases MCU security.

**Table 30-61. Erase All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 0            | 0x44 (ERSALL)        |

After clearing CCIF to launch the Erase All Blocks command, the FTFE erases all program flash memory, program flash swap IFR space, data flash memory, data flash IFR space, EEPROM backup memory, and FlexRAM, then verifies that all are erased.

If the FTFE verifies that all flash memories and the FlexRAM were properly erased, security is released by setting the FSEC[SEC] field to the unsecure state and the FCNFG[RAMRDY] bit is set. The Erase All Blocks command aborts if any flash or FlexRAM region is protected. The swap indicator address in the program flash blocks are not implicitly protected from the erase operation. The security byte and all other contents of the flash configuration field (see [Flash configuration field description](#)) are erased by the Erase All Blocks command. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks operation completes.

**Table 30-62. Erase All Blocks Command Error Handling**

| Error Condition  | Error Bit      |
|--|----------------|
| Command not available in current mode/security                                     | FSTAT[ACCERR]  |
| Any region of the program flash memory, data flash memory, or FlexRAM is protected | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation <sup>1</sup>          | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s All Blocks command to verify all bits are erased.

#### 30.4.12.12.1 Triggering an erase all external to the flash module

The functionality of the Erase All BlocksUnsecure command is also available in an uncommanded fashion outside of the flash memory. Refer to the device's Chip Configuration details for information on this functionality.

Before invoking the external erase all function, the FCCOB0 register must not contain 0x44. When invoked, the erase-all function erases all program flash memory, program flash swap IFR space, data flash memory, data flash IFR space, EEPROM backup, and FlexRAM regardless of the state of the FSTAT[ACCERR and FPVIOL] flags or the protection settings or the state of the flash swap system. If the post-erase verify passes, the routine releases security by setting the FSEC[SEC] field register to the unsecure state and the FCNFG[RAMRDY] bit sets. The security byte in the Flash Configuration Field is

also programmed to the unsecure state. The status of the erase-all request is reflected in the FCNFG[ERSAREQ] bit. The FCNFG[ERSAREQ] bit is cleared once the operation completes and the normal FSTAT error reporting is available as described in [Erase All Blocks Command](#).

### CAUTION

Since the IFR Swap Field in the program flash swap IFR containing the swap indicator address is erased during the Erase All Blocks command operation, the swap system becomes uninitialized. The Swap Control command must be run with the initialization code to set the swap indicator address and initialize the swap system.

#### 30.4.12.13 Verify Backdoor Access Key command

The Verify Backdoor Access Key command only executes if the mode and security conditions are satisfied (see [Flash commands by mode](#)). Execution of the Verify Backdoor Access Key command is further qualified by the FSEC[KEYEN] bits. The Verify Backdoor Access Key command releases security if user-supplied keys in the FCCOB match those stored in the Backdoor Comparison Key bytes of the Flash Configuration Field. The column labeled Flash Configuration Field offset address shows the location of the matching byte in the Flash Configuration Field.

**Table 30-63. Verify Backdoor Access Key Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] | Flash Configuration Field Offset Address |
|--------------|----------------------|--|
| 0            | 0x45 (VFYKEY)        |  |
| 1-3          | Not Used             |  |
| 4            | Key Byte 0           | 0x0_0003                                 |
| 5            | Key Byte 1           | 0x0_0002                                 |
| 6            | Key Byte 2           | 0x0_0001                                 |
| 7            | Key Byte 3           | 0x0_0000                                 |
| 8            | Key Byte 4           | 0x0_0007                                 |
| 9            | Key Byte 5           | 0x0_0006                                 |
| A            | Key Byte 6           | 0x0_0005                                 |
| B            | Key Byte 7           | 0x0_0004                                 |

After clearing CCIF to launch the Verify Backdoor Access Key command, the FTFE checks the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the FTFE sets the FSTAT[ACCERR] bit and terminates. If the command is enabled, the FTFE compares the key provided in FCCOB to the backdoor comparison key in the Flash

Configuration Field. If the backdoor keys match, the FSEC[SEC] field is changed to the unsecure state and security is released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are immediately aborted and the FSTAT[ACCERR] bit is (again) set to 1 until a reset of the FTFE module occurs. If the entire 8-byte key is all zeros or all ones, the Verify Backdoor Access Key command fails with an access error. The CCIF flag is set after the Verify Backdoor Access Key operation completes.

**Table 30-64. Verify Backdoor Access Key Command Error Handling**

| Error Condition  | Error Bit     |
|--|---------------|
| Command not available in current mode/security   | FSTAT[ACCERR] |
| The supplied key is all-0s or all-Fs   | FSTAT[ACCERR] |
| An incorrect backdoor key is supplied  | FSTAT[ACCERR] |
| Backdoor key access has not been enabled (see the description of the FSEC register)          | FSTAT[ACCERR] |
| This command is launched and the backdoor key has mismatched since the last power down reset | FSTAT[ACCERR] |

**30.4.12.14 Swap Control command (program flash only devices)**

The Swap Control command handles specific activities associated with swapping the two halves of program flash memory within the memory map.

**Table 30-65. Swap Control Command FCCOB Requirements**

| FCCOB Number    | FCCOB Contents [7:0]   |
|-----------------|--|
| 0               | 0x46 (SWAP)  |
| 1               | Flash address [23:16]  |
| 2               | Flash address [15:8]   |
| 3               | Flash address [7:0] <sup>1</sup>   |
| 4               | Swap Control Code:<br>0x01 - Initialize Swap System<br>0x02 - Set Swap in Update State<br>0x04 - Set Swap in Complete State<br>0x08 - Report Swap Status |
| Returned values |  |

*Table continues on the next page...*

**Table 30-65. Swap Control Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0]   |
|--------------|--|
| 5            | Current Swap Mode:<br>0x00 - Uninitialized<br>0x01 - Ready<br>0x02 - Update<br>0x03 - Update-Erased<br>0x04 - Complete   |

| 7            | Next Swap Block Status (after any reset):<br>For devices with FlexNVM:<br>0x00 - Program flash block 0 at 0x0_0000<br>0x01 - Program flash block 1 at 0x0_0000<br>For devices with program flash only:<br>0x00 - Program flash block 0/1 at 0x0_0000<br>0x01 - Program flash block 2/3 at 0x0_0000 |

1. Must be 128-bit aligned (Flash address [3:0] = 0000).

Upon clearing CCIF to launch the Swap Control command, the FTFE will handle swap-related activities based on the Swap Control code provided in FCCOB4 as follows:

- 0x01 (Initialize Swap System to UPDATE-ERASED State) - After verifying that the current swap state is UNINITIALIZED, and that both phrases which will contain the swap indicators (located in each half of the Program flash memory within the relative double-phrase flash address provided) are erased, and that the flash address provided is in the lower half of Program flash memory but not in the Flash Configuration Field, the flash address provided (shifted with bits[3:0] removed) will be programmed into the IFR Swap Field found in the program flash swap IFR. After the swap indicator address has been programmed into the IFR Swap Field, the swap enable word will be programmed to 0x0000. After the swap enable word has been programmed, the swap indicator located in the lower half of the Program flash memory will be programmed to 0xFF00.
- 0x02 (Progress Swap to UPDATE State) - After verifying that the current swap state is READY and that the aligned flash address provided matches the one stored in the

IFR Swap Field, the swap indicator located in the currently active program flash block will be programmed to 0xFF00.

- 0x04 (Progress Swap to COMPLETE State) - After verifying that the current swap state is UPDATE-ERASED and that the aligned flash address provided matches the one stored in the IFR Swap Field, the swap indicator located in the currently active program flash block will be programmed to 0x0000. Before executing with this Swap Control code, the user must erase the non-active swap indicator using the Erase Flash Block or Erase Flash Sector commands and update the application code or data as needed. The non-active swap indicator will be checked at the erase verify level and if the check fails, the current swap state will be changed to UPDATE with ACCERR set.
- 0x08 (Report Swap Status) - After verifying that the aligned flash address provided is in the lower half of Program flash memory but not in the Flash Configuration Field, the status of the swap system will be reported as follows:
  - FCCOB5 (Current Swap State) - indicates the current swap state based on the status of the swap enable word and the swap indicators. If the MGSTAT0 flag is set after command completion, the swap state returned was not successfully transitioned from and the appropriate swap command code must be attempted again. If the current swap state is UPDATE and the non-active swap indicator is 0xFFFF, the current swap state is changed to UPDATE-ERASED.
  - FCCOB6 (Current Swap Block Status) - indicates which program flash block is currently located at relative flash address 0x0\_0000.
  - FCCOB7 (Next Swap Block Status) - indicates which program flash block will be located at relative flash address 0x0\_0000 after the next reset of the FTFE module.
- 0x10 (Disable Swap System) - After verifying that the current swap state is UNINITIALIZED, the swap disable word, located in the IFR Swap Field, is programmed to 0x0000 and the swap system changed to the DISABLED state with Program flash block 0 located at relative flash address 0x0\_0000.

#### NOTE

It is recommended that the user execute the Swap Control command to report swap status (code 0x08) after any reset to determine if issues with the swap system were detected during the swap state determination procedure.

#### NOTE

It is recommended that the user write 0xFF to FCCOB5, FCCOB6, and FCCOB7 since the Swap Control command will not always return the swap state and status fields when an ACCERR is detected.

The CCIF flag is set after the Swap Control operation has completed.

## Functional Description

The swap indicators are implicitly protected from being programmed during Program Phrase or Program Section command operations and are implicitly unprotected during Swap Control command operations. The swap indicators are implicitly protected from being erased during Erase Flash Block and Erase Flash Sector command operations unless the swap indicator being erased is in the non-active program flash block and the swap system is in the UPDATE or UPDATE-ERASED state. The Erase All Blocks command or erase-all function can be used to place the swap system in the UNINITIALIZED state.

**Table 30-66. Swap Control Command Error Handling**

| Error Condition   | Swap Control Code | Error Bit      |
|---|-------------------|----------------|
| Command not available in current mode/security <sup>1</sup>   | All               | FSTAT[ACCERR]  |
| Flash address is not in the lower half of program flash memory  | All               | FSTAT[ACCERR]  |
| Flash address is in the Flash Configuration Field   | All               | FSTAT[ACCERR]  |
| Flash address is not 128-bit aligned  | All               | FSTAT[ACCERR]  |
| Flash address does not match the swap indicator address in the IFR  | 2, 4              | FSTAT[ACCERR]  |
| Swap initialize requested when phrase containing swap indicator (in each half of program flash memory) is not in the erased state | 1                 | FSTAT[ACCERR]  |
| Swap initialize requested when swap system is not in the uninitialized state  | 1                 | FSTAT[ACCERR]  |
| Swap update requested when swap system is not in the ready state  | 2                 | FSTAT[ACCERR]  |
| Swap complete requested when swap system is not in the update-erased state  | 4                 | FSTAT[ACCERR]  |
| An undefined swap control code is provided  | -                 | FSTAT[ACCERR]  |
| Any errors have been encountered during the swap determination and program-verify operations                                      | 1, 2, 4           | FSTAT[MGSTAT0] |
| Any brownouts were detected during the swap determination procedure   | 8                 | FSTAT[MGSTAT0] |

1. Returned fields will not be updated, i.e. no swap state or status reporting

**Block0 Active States    Block1 Active States**

**Figure 30-36. Valid Swap State Sequencing**

**Table 30-67. Swap State Report Mapping**

| Case            | Swap Enable Field <sup>1</sup> | Swap Indicator 0 <sup>1</sup> | Swap Indicator 1 <sup>1</sup> | Swap State <sup>2</sup> | State Code | MGSTAT0 | Active Block |
|-----------------|--------------------------------|-------------------------------|-------------------------------|-------------------------|------------|---------|--------------|
| 1               | 0xFFFF                         | -                             | -                             | Uninitialized           | 0          | 0       | 0            |
| 2               | 0x0000                         | 0xFF00                        | 0x0000                        | Update                  | 2          | 0       | 0            |
| 3               | 0x0000                         | 0xFF00                        | 0xFFFF                        | Update-Erased           | 3          | 0       | 0            |
| 4               | 0x0000                         | 0x0000                        | 0xFFFF <sup>3</sup>           | Complete <sup>4</sup>   | 4          | 0       | 0            |
| 5               | 0x0000                         | 0x0000                        | 0xFFFF                        | Ready <sup>5</sup>      | 1          | 0       | 1            |

| 27              | 0x0000                         | 0XXXXX                        | 0xFFFF                        | Update-Erased           | 3          | 1       | 0            |
| 28              | 0x0000                         | 0xFFFF                        | 0XX00                         | Update-Erased           | 3          | 1       | 1            |
| 29              | 0x0000                         | 0xFFFF                        | 0XXXXX                        | Update-Erased           | 3          | 1       | 1            |

1. 0XXXXX, 0xFFXX, 0XX00 indicates a non-valid value was read; 0xFF(00) indicates more 0's than other indicator (if same number of 0's, then swap system defaults to block 0 active)
2. Cases 10-29 due to brownout (abort) detected during program or erase steps related to swap
3. Must read 0xFFFF with erase verify level before transition to Complete allowed
4. No reset since successful Swap Complete execution
5. Reset after successful Swap Complete execution
6. Not a valid case
7. Fails to read 0xFFFF at erase verify level

### 30.4.12.14.1 Swap state determination

During the reset sequence, the state of the swap system is determined by evaluating the IFR Swap Field in the program flash swap IFR and the swap indicators found within the double-phrase containing the relative swap indicator address in each half of the program flash memory.

**Table 30-68. Program Flash Swap IFR Fields**

| Address Range | Size (Bytes) | Field Description      |
|---------------|--------------|------------------------|
| 0x000 – 0x001 | 2            | Swap Indicator Address |
| 0x002 – 0x003 | 2            | Swap Enable Word       |
| 0x004 – 0x3FF | 1020         | Reserved               |

### 30.4.12.15 Program Partition command

The Program Partition command prepares the FlexNVM block for use as data flash, EEPROM backup, or a combination of both and initializes the FlexRAM. The Program Partition command must not be launched from flash memory, since flash memory resources are not accessible during Program Partition command execution.

#### CAUTION

While different partitions of the FlexNVM are available, the intention is that a single partition choice is used throughout the entire lifetime of a given application. The FlexNVM Partition Code choices affect the endurance and data retention characteristics of the device.

**Table 30-69. Program Partition Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                   |
|--------------|--|
| 0            | 0x80 (PGMPART)                         |
| 1            | Not Used                               |
| 2            | Not Used                               |
| 3            | Not Used                               |
| 4            | EEPROM Data Set Size Code <sup>1</sup> |
| 5            | FlexNVM Partition Code <sup>2</sup>    |

**Table 30-70. Valid EEPROM Data Set Size Codes (continued)**

| EEPROM Data Set Size Code (FCCOB4) <sup>1</sup> |                       | EEPROM Data Set Size (Bytes)<br>Subsystem A + B |
|---|-----------------------|---|
| EEESPLIT (FCCOB4[5:4])                          | EEESIZE (FCCOB4[3:0]) |   |
| 00 <sup>4</sup>                                 | 0x1                   | 1,024 + 7,168                                   |
| 01 <sup>4</sup>                                 |                       | 2,048 + 6,144                                   |
| 10  |                       | 4,096 + 4,096                                   |
| 11  |                       | 4,096 + 4,096                                   |
| 00 <sup>5</sup>                                 | 0x0 <sup>4</sup>      | 2,048 + 14,336                                  |
| 01 <sup>5</sup>                                 |                       | 4,096 + 12,288                                  |
| 10  |                       | 8,192 + 8,192                                   |
| 11  |                       | 8,192 + 8,192                                   |

1. FCCOB4[7:6] = 00
2. EEPROM Data Set Size must be set to 0 Bytes when the FlexNVM Partition Code is set for no EEPROM.
3. Not a valid case for 32 Kbytes of EEPROM backup.
4. Not a valid case for 64 Kbytes of EEPROM backup.
5. Not a valid case for 128 Kbytes of EEPROM backup.

**Table 30-71. Valid FlexNVM Partition Codes**

| FlexNVM Partition Code DEPART<br>(FCCOB5[3:0]) <sup>1</sup> | Data flash Size (Kbytes) | EEPROM-backup Size (Kbytes) |
|---|--------------------------|-----------------------------|
| 0000  | 256                      | 0                           |
| 0100  | 192                      | 64                          |
| 0101  | 128                      | 128                         |
| 0110  | 0                        | 256                         |
| 1000  | 0                        | 256                         |
| 1100  | 64                       | 192                         |
| 1101  | 128                      | 128                         |
| 1110  | 256                      | 0                           |

1. FCCOB5[7:4] = 0000

After clearing CCIF to launch the Program Partition command, the FTFE first verifies that the EEPROM Data Set Size Code and FlexNVM Partition Code in the data flash IFR are erased. If erased, the Program Partition command erases the contents of the FlexNVM memory. If the FlexNVM is to be partitioned for EEPROM backup, the allocated EEPROM backup sectors are formatted for EEPROM use. Finally, the partition codes are programmed into the data flash IFR using the values provided. The Program Partition command also verifies that the partition codes read back correctly after programming. The CCIF flag is set after the Program Partition operation completes.

## Functional Description

Prior to launching the Program Partition command, the data flash IFR must be in an erased state, which can be accomplished by executing the Erase All Blocks command or by an external request (see [Erase All Blocks Command](#)). The EEPROM Data Set Size Code and FlexNVM Partition Code are read using the Read Resource command (see [Read Resource Command](#)).

**Table 30-72. Program Partition Command Error Handling**

| Error Condition   | Error Bit      |
|---|----------------|
| Command not available in current mode/security  | FSTAT[ACCERR]  |
| The EEPROM data size and FlexNVM partition code bytes are not initially 0xFFFF  | FSTAT[ACCERR]  |
| Invalid EEPROM Data Set Size Code is entered (see <a href="#">Table 30-70</a> for valid codes)                          | FSTAT[ACCERR]  |
| Invalid FlexNVM Partition Code is entered (see <a href="#">Table 30-71</a> for valid codes)                             | FSTAT[ACCERR]  |
| FlexNVM Partition Code = full data flash (no EEPROM) and EEPROM Data Set Size Code allocates FlexRAM for EEPROM         | FSTAT[ACCERR]  |
| FlexNVM Partition Code allocates space for EEPROM backup, but EEPROM Data Set Size Code allocates no FlexRAM for EEPROM | FSTAT[ACCERR]  |
| FCCOB4[7:6] != 00   | FSTAT[ACCERR]  |
| FCCOB5[7:4] != 0000   | FSTAT[ACCERR]  |
| Any errors have been encountered during the verify operation  | FSTAT[MGSTAT0] |

### 30.4.12.16 Set FlexRAM Function command

The Set FlexRAM Function command changes the function of the FlexRAM:

- When not partitioned for EEPROM, the FlexRAM is typically used as traditional RAM.
- When partitioned for EEPROM, the FlexRAM is typically used to store EEPROM data.

**Table 30-73. Set FlexRAM Function Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]  |
|--------------|---|
| 0            | 0x81 (SETRAM)   |
| 1            | FlexRAM Function Control Code<br>(see <a href="#">Table 30-74</a> ) |

**Table 30-74. FlexRAM Function Control**

| FlexRAM Function Control Code | Action   |
|-------------------------------|--|
| 0xFF                          | Make FlexRAM available as RAM: <ul style="list-style-type: none"> <li>• Clear the FCNFG[RAMRDY] and FCNFG[EEERDY] flags</li> <li>• Write a background of ones to all FlexRAM locations</li> <li>• Set the FCNFG[RAMRDY] flag</li> </ul>  |
| 0x00                          | Make FlexRAM available for EEPROM: <ul style="list-style-type: none"> <li>• Clear the FCNFG[RAMRDY] and FCNFG[EEERDY] flags</li> <li>• Write a background of ones to all FlexRAM locations</li> <li>• Copy-down existing EEPROM data to FlexRAM</li> <li>• Set the FCNFG[EEERDY] flag</li> </ul> |

After clearing CCIF to launch the Set FlexRAM Function command, the FTFE sets the function of the FlexRAM based on the FlexRAM Function Control Code.

When making the FlexRAM available as traditional RAM, the FTFE clears the FCNFG[EEERDY] and FCNFG[RAMRDY] flags, overwrites the contents of the entire FlexRAM with a background pattern of all ones, and sets the FCNFG[RAMRDY] flag. The state of the EPROT register does not prevent the FlexRAM from being overwritten. When the FlexRAM is set to function as a RAM, normal read and write accesses to the FlexRAM are available. When large sections of flash memory need to be programmed, e.g. during factory programming, the FlexRAM can be used as the Section Program Buffer for the Program Section command (see [Program Section command](#)).

When making the FlexRAM available for EEPROM, the FTFE clears the FCNFG[RAMRDY] and FCNFG[EEERDY] flags, overwrites the contents of the FlexRAM allocated for EEPROM with a background pattern of all ones, and copies the existing EEPROM data from the EEPROM backup record space to the FlexRAM. After completion of the EEPROM copy-down, the FCNFG[EEERDY] flag is set. When the FlexRAM is set to function as EEPROM, normal read and write access to the FlexRAM is available, but writes to the FlexRAM also invoke EEPROM activity.

The CCIF flag will be set after the Set FlexRAM Function operation has completed.

**Table 30-75. Set FlexRAM Function Command Error Handling**

| Error Condition  | Error Bit     |
|--|---------------|
| Command not available in current mode/security   | FSTAT[ACCERR] |
| FlexRAM Function Control Code is not defined   | FSTAT[ACCERR] |
| FlexRAM Function Control Code is set to make the FlexRAM available for EEPROM, but FlexNVM is not partitioned for EEPROM | FSTAT[ACCERR] |

### 30.4.13 Security

The FTFE module provides security information to the MCU based on contents of the FSEC security register. The MCU then limits access to FTFE resources as defined in the device's Chip Configuration details. During reset, the FTFE module initializes the FSEC register using data read from the security byte of the Flash Configuration Field (see [Flash configuration field description](#)).

The following fields are available in the FSEC register. Details of the settings are described in the FSEC register description.

**Table 30-76. FSEC fields**

| FSEC field | Description              |
|------------|--------------------------|
| KEYEN      | Backdoor Key Access      |
| MEEN       | Mass Erase Capability    |
| FSLACC     | Freescall Factory Access |
| SEC        | MCU security             |

#### 30.4.13.1 FTFE Access by Mode and Security

The following table summarizes how access to the FTFE module is affected by security and operating mode.

**Table 30-77. FTFE Access Summary**

| Operating Mode | MCU Security State |  |
|----------------|--------------------|--|
|                | Unsecure           | Secure   |
| NVM Normal     | Full command set   |  |
| NVM Special    | Full command set   | Only the Erase All Blocks and Read 1s All Blocks commands. |

#### 30.4.13.2 Changing the Security State

The security state out of reset can be permanently changed by programming the security byte of the flash configuration field. This assumes that you are starting from a mode where the necessary program flash erase and program commands are available and that the region of the program flash containing the flash configuration field is unprotected. If the flash security byte is successfully programmed, its new value takes affect after the next MCU reset.

### 30.4.13.2.1 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash configuration field description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key command](#)) can be run which allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e. 0x0000\_0000\_0000\_0000 and 0xFFFF\_FFFF\_FFFF\_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key command](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash configuration field description](#)). After the next reset of the MCU, the security state of the FTFE module reverts back to the Flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

### 30.4.14 Reset Sequence

On each system reset the FTFE module executes a sequence which establishes initial values for the flash block configuration parameters, FPROT, FDPROT, FEPROT, FOPT, and FSEC registers and the FCNFG[SWAP, PFLSH, RAMRDY, EEERDY] bits.

CCIF is cleared throughout the reset sequence. The FTFE module holds off all CPU access for a portion of the reset sequence. Flash reads are possible when the hold is removed. Completion of the reset sequence is marked by setting CCIF which enables flash user commands.

If a reset occurs while any FTFE command is in progress, that command is immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed. Commands and operations do not automatically resume after exiting reset.

# Chapter 31

## EzPort

### 31.1 Overview

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The EzPort module is a serial flash programming interface that enables In-System Programming (ISP) of flash memory contents in a 32-bit general-purpose microcontroller. Memory contents can be read/erased/programmed from an external source, in a format that is compatible with many standalone flash memory chips, without requiring the removal of the microcontroller from the system board.

### 31.1.1 Block diagram

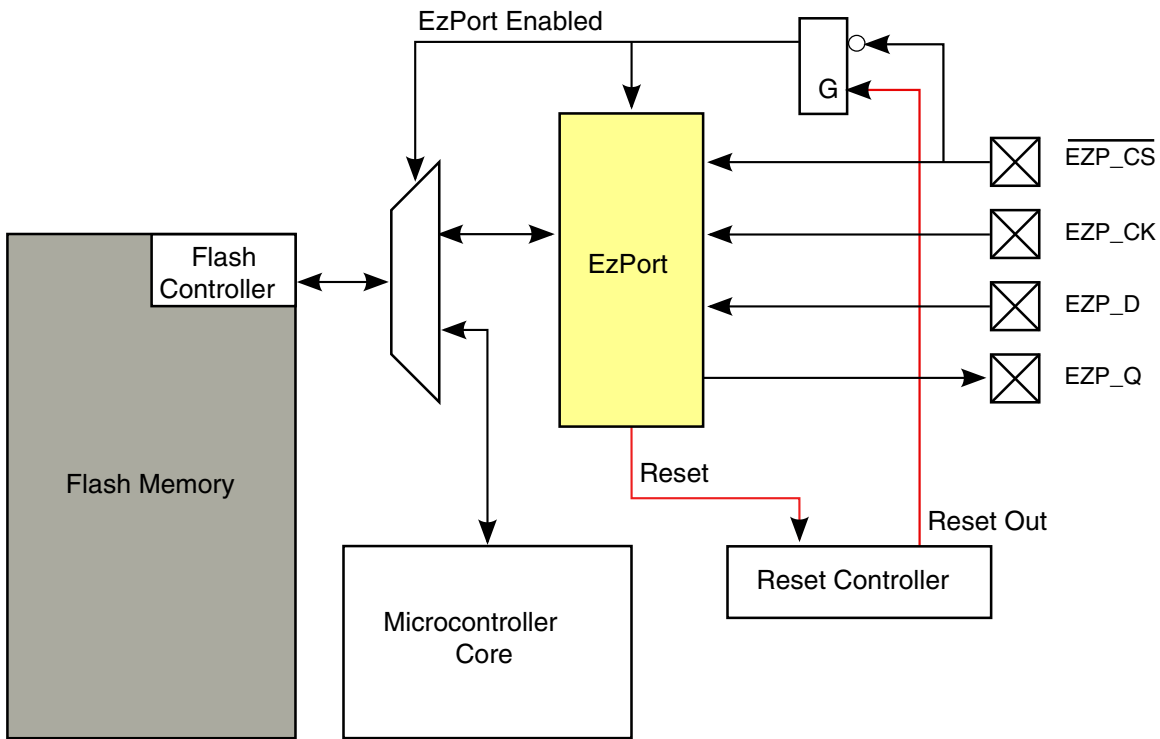

Figure 31-1. EzPort block diagram

### 31.1.2 Features

EzPort includes the following features:

- Serial interface that is compatible with a subset of the SPI format.
- Ability to read, erase, and program flash memory.
- Ability to reset the microcontroller, allowing it to boot from the flash memory after the memory has been configured.

### 31.1.3 Modes of operation

The EzPort can operate in one of two modes, enabled or disabled.

- Enabled — When enabled, the EzPort steals access to the flash memory, preventing access from other cores or peripherals. The rest of the microcontroller is disabled to avoid conflicts. The flash is configured for NVM Special mode.
- Disabled — When the EzPort is disabled, the rest of the microcontroller can access flash memory as normal.

The EzPort provides a simple interface to connect an external device to the flash memory on board a 32 bit microcontroller. The interface itself is compatible with the SPI interface, with the EzPort operating as a slave, running in either of the two following modes. The data is transmitted with the most significant bit first.

- CPOL = 0, CPHA = 0
- CPOL = 1, CPHA = 1

Commands are issued by the external device to erase, program, or read the contents of the flash memory. The serial data out from the EzPort is tri-stated unless data is being driven. This allows the signal to be shared among several different EzPort (or compatible) devices in parallel, as long as they have different chip-selects.

## 31.2 External signal descriptions

After the table of EzPort external signals, subsequent sections explain the signals in more detail.

**Table 31-1. EzPort external signals**

| JTAG (cJTAG) Signal | External Signal | Name                   | I/O    |
|---------------------|-----------------|------------------------|--------|
| TCK (TCKC)          | EZP_CK          | EzPort Clock           | Input  |
| TMS (TMSC)          | EZP_CS          | EzPort Chip Select     | Input  |
| TDI (TDIC)          | EZP_D           | EzPort Serial Data In  | Input  |
| TDO (TDOC)          | EZP_Q           | EzPort Serial Data Out | Output |

### 31.2.1 EzPort Clock (EZP\_CK)

EZP\_CK is the serial clock for data transfers. The serial data in (EZP\_D) and chip select ( $\overline{\text{EZP\_CS}}$ ) are registered on the rising edge of EZP\_CK, while serial data out (EZP\_Q) is driven on the falling edge of EZP\_CK.

The maximum frequency of the EzPort clock is half the system clock frequency for all commands, except when executing the Read Data or Read FlexRAM commands. When executing the Read Data or Read FlexRAM commands, the EzPort clock has a maximum frequency of 1/8 the system clock frequency.

### 31.2.2 EzPort Chip Select ( $\overline{\text{EZP\_CS}}$ )

$\overline{\text{EZP\_CS}}$  is the chip select for signaling the start and end of serial transfers. While  $\overline{\text{EZP\_CS}}$  is asserted, if the microcontroller's reset out signal is negated, then EzPort is enabled out of reset; otherwise EzPort is disabled. After EzPort is enabled, asserting  $\overline{\text{EZP\_CS}}$  starts a serial data transfer, which continues until  $\overline{\text{EZP\_CS}}$  is negated again. The negation of  $\overline{\text{EZP\_CS}}$  indicates that the current command has finished and resets the EzPort state machine, so that EzPort is ready to receive the next command.

### 31.2.3 EzPort Serial Data In ( $\text{EZP\_D}$ )

$\text{EZP\_D}$  is the serial data in for data transfers.  $\text{EZP\_D}$  is registered on the rising edge of  $\text{EZP\_CK}$ . All commands, addresses, and data are shifted in most significant bit first. When the EzPort is driving output data on  $\text{EZP\_Q}$ , the data shifted in  $\text{EZP\_D}$  is ignored.

### 31.2.4 EzPort Serial Data Out ( $\text{EZP\_Q}$ )

$\text{EZP\_Q}$  is the serial data out for data transfers.  $\text{EZP\_Q}$  is driven on the falling edge of  $\text{EZP\_CK}$ . It is tri-stated unless  $\overline{\text{EZP\_CS}}$  is asserted and the EzPort is driving data out. All data is shifted out most significant bit first.

## 31.3 Command definition

The EzPort receives commands from an external device and translates the commands into flash memory accesses. The following table lists the supported commands.

**Table 31-2. EzPort commands**

| Command | Description          | Code | Address Bytes | Data Bytes | Accepted when secure? |
|---------|----------------------|------|---------------|------------|-----------------------|
| WREN    | Write Enable         | 0x06 | 0             | 0          | Yes                   |
| WRDI    | Write Disable        | 0x04 | 0             | 0          | Yes                   |
| RDSR    | Read Status Register | 0x05 | 0             | 1          | Yes                   |

*Table continues on the next page...*

**Table 31-2. EzPort commands (continued)**

| Command         | Description                        | Code | Address Bytes  | Data Bytes                | Accepted when secure? |
|-----------------|------------------------------------|------|----------------|---------------------------|-----------------------|
| READ            | Flash Read Data                    | 0x03 | 3 <sup>1</sup> | 1+                        | No                    |
| FAST_READ       | Flash Read Data at High Speed      | 0x0B | 3 <sup>1</sup> | 1+ <sup>2</sup>           | No                    |
| SP              | Flash Section Program              | 0x02 | 3 <sup>3</sup> | 16 - SECTION <sup>4</sup> | No                    |
| SE              | Flash Sector Erase                 | 0xD8 | 3 <sup>3</sup> | 0                         | No                    |
| BE              | Flash Bulk Erase                   | 0xC7 | 0              | 0                         | Yes <sup>5</sup>      |
| RESET           | Reset Chip                         | 0xB9 | 0              | 0                         | Yes                   |
| WRFCCOB         | Write FCCOB Registers              | 0xBA | 0              | 12                        | Yes <sup>6</sup>      |
| FAST_RDFFCOB    | Read FCCOB registers at high speed | 0xBB | 0              | 1 - 12 <sup>2</sup>       | No                    |
| WRFLEXRAM       | Write FlexRAM                      | 0xBC | 3 <sup>1</sup> | 4                         | No                    |
| RDFLEXRAM       | Read FlexRAM                       | 0xBD | 3 <sup>1</sup> | 1+                        | No                    |
| FAST_RDFFLEXRAM | Read FlexRAM at high speed         | 0xBE | 3 <sup>1</sup> | 1+ <sup>2</sup>           | No                    |

1. Address must be 32-bit aligned (two LSBs must be zero).
2. One byte of dummy data must be shifted in before valid data is shifted out.
3. Address must be 128-bit aligned (four LSBs must be zero).
4. Please see the Flash Memory chapter for a definition of section size. Total number of data bytes programmed must be a multiple of 16.
5. Bulk Erase is accepted when security is set and only when the BEDIS status field is not set.
6. The flash will be in NVM Special mode, restricting the type of commands that can be executed through WRITE\_FCCOB when security is enabled.

## 31.3.1 Command descriptions

This section describes the module commands.

### 31.3.1.1 Write Enable

**Figure 31-2. Write Enable command sequence**

**Command definition**

The Write Enable (WREN) command sets the write enable register field in the EzPort status register. The write enable field must be set for a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) to be accepted. The write enable register field clears on reset, on a Write Disable command, and at the completion of write command. This command must not be used if a write is already in progress.

### 31.3.1.2 Write Disable

**Figure 31-3. Write Disable command sequence**

The Write Disable (WRDI) command clears the write enable register field in the status register. This command must not be used if a write is already in progress.

### 31.3.1.3 Read Status Register

**Figure 31-4. Read Status Register command sequence**

The Read Status Register (RDSR) command returns the contents of the EzPort status register.

**Table 31-3. EzPort status register**

|   | 7  | 6   | 5 | 4 | 3       | 2     | 1   | 0   |
|---|----|-----|---|---|---------|-------|-----|-----|
| R | FS | WEF |   |   | FLEXRAM | BEDIS | WEN | WIP |

*Table continues on the next page...*

**Table 31-3. EzPort status register (continued)**

|        |                  |   |   |   |                  |                  |   |                |
|--------|------------------|---|---|---|------------------|------------------|---|----------------|
| W      |                  |   |   |   |                  |                  |   |                |
| Reset: | 0/1 <sup>1</sup> | 0 | 0 | 0 | 0/1 <sup>2</sup> | 0/1 <sup>3</sup> | 0 | 1 <sup>4</sup> |

1. Reset value reflects the status of flash security out of reset.
2. Reset value reflects FlexNVM flash partitioning. If FlexNVM flash has been partitioned for EEPROM, this field is set immediately after reset. Note that FLEXRAM is cleared after the EzPort initialization sequence completes, as indicated by clearing of WIP.
3. Reset value reflects whether bulk erase is enabled or disabled out of reset.
4. Initial value of WIP is 1, but the value clears to 0 after EzPort initialization is complete.

**Table 31-4. EzPort status register field description**

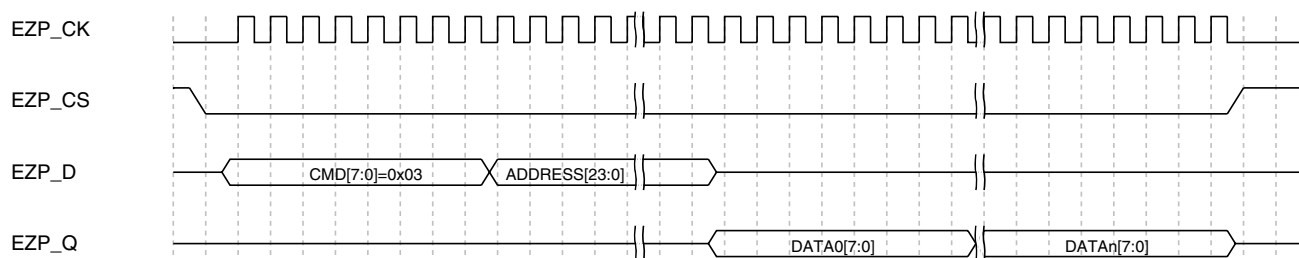

| Field        | Description   |
|--------------|---|
| 0<br>WIP     | <p>Write in progress.</p> <p>Sets after a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) is accepted and clears after the flash memory has completed all operations associated with the write command, as indicated by the Command Complete Interrupt Flag (CCIF) inside the flash. This field is also asserted on reset and cleared when EzPort initialization is complete. Only the Read Status Register (RDSR) command is accepted while a write is in progress.</p> <p>0 = Write is not in progress. Accept any command.<br/>1 = Write is in progress. Only accept RDSR command.</p>                                   |
| 1<br>WEN     | <p>Write enable</p> <p>Enables the write command that follows. It is a control field that must be set before a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM) is accepted. Is set by the Write Enable (WREN) command and cleared by reset or a Write Disable (WRDI) command. This field also clears when the flash memory has completed all operations associated with the command.</p> <p>0 = Disables the following write command.<br/>1 = Enables the following write command.</p>  |
| 2<br>BEDIS   | <p>Bulk erase disable</p> <p>Indicates whether bulk erase (BE) is disabled when flash is secure.</p> <p>0 = BE is enabled.<br/>1 = BE is disabled if FS is also set. Attempts to issue a BE command will result in the WEF flag being set.</p>  |
| 3<br>FLEXRAM | <p>FlexRAM mode</p> <p>Indicates the current mode of the FlexRAM. Valid only when WIP is cleared.</p> <p>0 = FlexRAM is in RAM mode. RD/WRFLEXRAM command can be used to read/write data in FlexRAM.<br/>1 = FlexRAM is in EEPROM mode. SP command is not accepted. RD/WRFLEXRAM command can be used to read/write data in the FlexRAM.</p>   |
| 6<br>WEF     | <p>Write error flag</p> <p>Indicates whether there has been an error while executing a write command (SP, SE, BE, WRFCCOB, or WRFLEXRAM). The WEF flag will set if Flash Access Error Flag (ACCERR), Flash Protection Violation (FPVIOL), or Memory Controller Command Completion Status (MGSTAT0) inside the flash memory is set at the completion of the write command. See the flash memory chapter for further description of these flags and their sources. The WEF flag clears after a Read Status Register (RDSR) command.</p> <p>0 = No error on previous write command.<br/>1 = Error on previous write command.</p> |

*Table continues on the next page...*

**Table 31-4. EzPort status register field description (continued)**

| Field   | Description   |
|---------|---|
| 7<br>FS | Flash security<br>Indicates whether the flash is secure. See <a href="#">Table 31-2</a> for the list of commands that will be accepted when flash is secure. Flash security can be disabled by performing a BE command.<br>0 = Flash is not secure.<br>1 = Flash is secure. |

### 31.3.1.4 Read Data

**Figure 31-5. Read command sequence**

The Read Data (READ) command returns data from the flash memory or FlexNVM, depending on the initial address specified in the command word. The initial address must be 32-bit aligned with the two LSBs being zero.

Data continues being returned for as long as the EzPort chip select ( $\overline{\text{EZP\_CS}}$ ) is asserted, with the address automatically incrementing. In this way, the entire contents of flash can be returned by one command. Attempts to read from an address which does not fall within the valid address range for the flash memory regions returns unknown data. See [Flash memory map for EzPort access](#).

For this command to return the correct data, the EzPort clock (EZP\_CK) must run at the internal system clock divided by eight or slower. This command is not accepted if the WEF, WIP, or FS field in the EzPort status register is set.

### 31.3.1.5 Read Data at High Speed

**Figure 31-6. Read Data at High Speed command sequence**

The Read Data at High Speed (FAST\_READ) command is identical to the READ command, except for the inclusion of a dummy byte following the address bytes and before the first data byte is returned.

This command can be run with an EzPort clock (EZP\_CK) frequency of half the internal system clock frequency of the microcontroller or slower. This command is not accepted if the WEF, WIP, or FS field in the EzPort status register is set.

### 31.3.1.6 Section Program

**Figure 31-7. Section Program command sequence**

The Section Program (SP) command programs up to one section of flash memory that has previously been erased. Please see the Flash Memory chapter for a definition of section size. The starting address of the memory to program is sent after the command word and must be a 128-bit aligned address with the four LSBs being zero.

As data is shifted in, the EzPort buffers the data in FlexRAM before executing an SP command within the flash. For this reason, the number of bytes to be programmed must be a multiple of 16 and up to one flash section can be programmed at a time. For more details, see the Flash Memory Module.

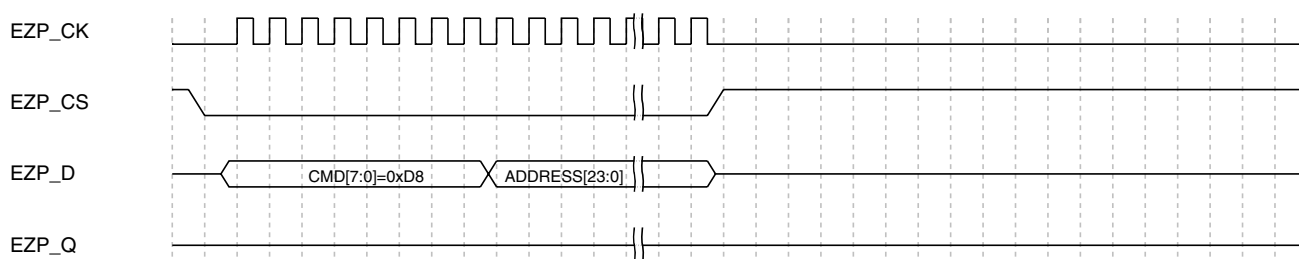

### Command definition

Attempts to program more than one section, across a sector boundary or from an initial address which does not fall within the valid address range for the flash causes the WEF flag to set. See [Flash memory map for EzPort access](#).

This command requires the FlexRAM to be configured for traditional RAM operation. By default, after entering EzPort mode, the FlexRAM is configured for traditional RAM operation. If the user reconfigures FlexRAM for EEPROM operation, then the user should use the WRFCCOB command to configure FlexRAM back to traditional RAM operation before issuing an SP command. See the Flash Memory chapter for details on how the FlexRAM function is modified.

This command is not accepted if the WEF, WIP, FLEXRAM, or FS field is set or if the WEN field is not set in the EzPort status register.

### 31.3.1.7 Sector Erase

**Figure 31-8. Sector Erase command sequence**

The Sector Erase (SE) command erases the contents of one sector of flash memory. The three byte address sent after the command byte can be any address within the sector to erase, but must be a 128-bit aligned address (the four LSBs must be zero). Attempts to erase from an initial address which does not fall within the valid address range (see [Flash memory map for EzPort access](#)) for the flash results in the WEF flag being set.

This command is not accepted if the WEF, WIP or FS field is set or if the WEN field is not set in the EzPort status register.

### 31.3.1.8 Bulk Erase

**Figure 31-9. Bulk Erase command sequence**

The Bulk Erase (BE) command erases the entire contents of flash memory, ignoring any protected sectors or flash security. Flash security is disabled upon successful completion of the BE command.

Attempts to issue a BE command while the BEDIS and FS fields are set results in the WEF flag being set in the EzPort status register. Also, this command is not accepted if the WEF or WIP field is set or if the WEN field is not set in the EzPort status register.

### 31.3.1.9 EzPort Reset Chip

**Figure 31-10. Reset Chip command sequence**

The Reset Chip (RESET) command forces the chip into the reset state. If the EzPort chip select ( $\overline{\text{EZP\_CS}}$ ) pin is asserted at the end of the reset period, EzPort is enabled; otherwise, it is disabled. This command allows the chip to boot up from flash memory after being programmed by an external source.

This command is not accepted if the WIP field is set in the EzPort status register.

### 31.3.1.10 Write FCCOB Registers

**Figure 31-11. Write FCCOB Registers command sequence**

The Write FCCOB Registers (WRFCCOB) command allows the user to write to the flash common command object registers and execute any command allowed by the flash.

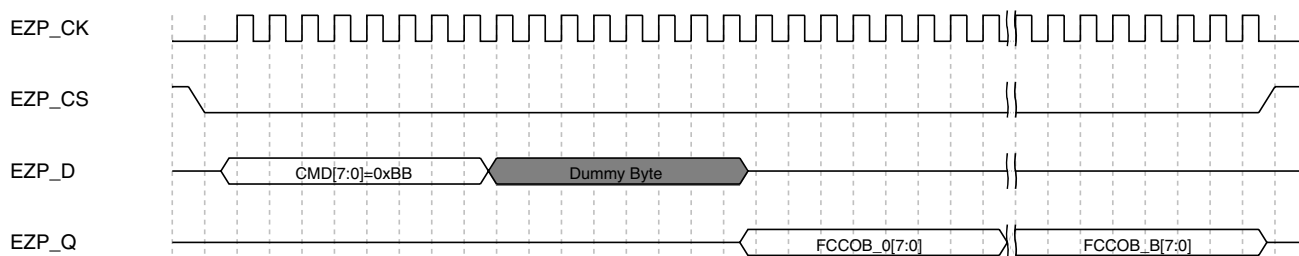

**NOTE**

When security is enabled, the flash is configured in NVM Special mode, restricting the commands that can be executed by the flash.

After receiving 12 bytes of data, EzPort writes the data to the FCCOB 0-B registers in the flash and then automatically launches the command within the flash. If greater or less than 12 bytes of data is received, this command has unexpected results and may result in the WEF flag being set.

This command is not accepted if the WEF or WIP field is set or if the WEN field is not set in the EzPort status register.

### 31.3.1.11 Read FCCOB Registers at High Speed

**Figure 31-12. Read FCCOB Registers at High Speed command sequence**

The Read FCCOB Registers at High Speed (FAST\_RDFCCOB) command allows the user to read the contents of the flash common command object registers. After receiving the command, EzPort waits for one dummy byte of data before returning FCCOB register data starting at FCCOB 0 and ending with FCCOB B.

This command can be run with an EzPort clock (EZP\_CK) frequency half the internal system clock frequency of the microcontroller or slower. Attempts to read greater than 12 bytes of data returns unknown data. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are 1.

### 31.3.1.12 Write FlexRAM

**Figure 31-13. Write FlexRAM command sequence**

The Write FlexRAM (WRFLEXRAM) command allows the user to write four bytes of data to the FlexRAM. If the FlexRAM is configured for EEPROM operation, the WRFLEXRAM command can effectively be used to create data records in the EEPROM flash memory.

By default, after entering EzPort mode, the FlexRAM is configured for traditional RAM operation and functions as direct RAM. The user can alter the FlexRAM configuration by using WRFCCOB to execute a Set FlexRAM or Program Partition command within the flash.

The address of the FlexRAM location to be written is sent after the command word and must be a 32-bit aligned address (the two LSBs must be zero). Attempts to write an address which does not fall within the valid address range for the FlexRAM results in the value of the WEF flag being 1. See [Flash memory map for EzPort access](#) for more information.

After receiving four bytes of data, EzPort writes the data to the FlexRAM. If greater or less than four bytes of data is received, this command has unexpected results and may result in the value of the WEF flag being 1.

This command is not accepted if the WEF, WIP or FS fields are 1 or if the WEN field is 0 in the EzPort status register.

### 31.3.1.13 Read FlexRAM

**Figure 31-14. Read FlexRAM command sequence**

The Read FlexRAM (RDFLEXRAM) command returns data from the FlexRAM. If the FlexRAM is configured for EEPROM operation, the RDFLEXRAM command can effectively be used to read data from EEPROM flash memory.

Data continues being returned for as long as the EzPort chip select ( $\overline{\text{EZP\_CS}}$ ) is asserted, with the address automatically incrementing. In this way, the entire contents of FlexRAM can be returned by one command.

The initial address must be 32-bit aligned (the two LSBs must be zero). Attempts to read from an address which does not fall within the valid address range for the FlexRAM returns unknown data. See [Flash memory map for EzPort access](#) for more information.

For this command to return the correct data, the EzPort clock (EZP\_CK) must run at the internal system clock divided by eight or slower. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are set.

### 31.3.1.14 Read FlexRAM at High Speed

**Figure 31-15. Read FlexRAM at High Speed command sequence**

The Read FlexRAM at High Speed (FAST\_RDFLEXRAM) command is identical to the RDFLEXRAM command, except for the inclusion of a dummy byte following the address bytes and before the first data byte is returned.

This command can be run with an EzPort clock (EZIP\_CK) frequency up to and including half the internal system clock frequency of the microcontroller. This command is not accepted if the WEF, WIP, or FS fields in the EzPort status register are set.

## 31.4 Flash memory map for EzPort access

The following table shows the flash memory map for access through EzPort.

### NOTE

The flash block address map for access through EzPort may not conform to the system memory map. Changes are made to allow the EzPort address width to remain 24 bits.

**Table 31-5. Flash Memory Map for EzPort Access**

| Valid start address | Size                                    | Flash block | Valid commands                           |
|---------------------|---|-------------|--|
| 0x0000_0000         | See device's chip configuration details | Flash       | READ, FAST_READ, SP, SE, BE              |
| 0x0000_0000         | See device's chip configuration details | FlexRAM     | RDFLEXRAM, FAST_RDFLEXRAM, WRFLEXRAM, BE |

# Chapter 32

## NAND Flash Controller (NFC)

### 32.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The NAND flash controller (NFC) interfaces to standard NAND flash memory devices. It is composed of various control logic units and a 9 KB SRAM buffer. The NFC provides a glueless interface to 8- and 16-bit NAND flash devices with page sizes of 512 bytes, 2 KB, 4 KB, 8 KB and 16 KB.

Throughout this chapter the following terms are used:

- Block — (specified by device) smallest erasable unit in a NAND device, consisting of multiple pages
- Page — (specified by device) unit of flash data containing main and spare areas
- Main area of a page — stores data
- Spare area of a page — stores ECC and other software information
- Sector — an elementary transfer unit
  - For devices with pages of 2KB and smaller, this is the same size of the page
  - For devices with pages larger than 2KB, the pages are split into multiple virtual pages. In this case, the sector size is the size of the virtual page
- Virtual page — is the physical page size divided by the splitting factor, `NFC_CFG[PAGECNT]`

- ECC — error-correcting code
- BCH (Bose Chaudhuri Hocquenghem) — cyclic error-correcting code that corrects multi-bit errors

### 32.1.1 Block Diagram

The following is a block diagram of the NAND flash controller.

Figure 32-1. NAND Flash Controller Block Diagram

### 32.1.2 Features

The NAND flash controller includes the following features:

- 8- and 16-bit NAND flash interface

- 9 KB RAM buffer
  - Memory-mapped registers and SRAM buffer
- Supports all NAND flash products regardless of density/organization
- Supports flash device commands, such as page read, page program, reset, block erase, read status, read ID, copy-back, multiplane read/program, interleaved read/program, random input/output, read in EDO mode.
- Integrated DMA engine
  - Two configurable DMA channels
    - Use DMA channel 1 only to read/write a page for main and spare area of a page
    - Use DMA channel 1 to read/write the main area of a page, and DMA channel 2 for the spare area
- ECC mode
  - In ECC mode, NFC supports 4/6/8/12/16/24/32-bit error correction.
  - ECC mode can be bypassed.

## 32.2 External Signal Description

The signals shown in the next table are used to control NAND flash device.

**Table 32-1. NFC Signal Properties**

| Name         | Function                   | I/O | Reset                |
|--------------|----------------------------|-----|----------------------|
| NFC_ALE      | Flash address latch enable | O   | 1                    |
| NFC_CE       | Flash chip enable          | O   | 1                    |
| NFC_CLE      | Flash command latch enable | O   | 1                    |
| NFC_R/B      | Flash ready/busy           | I   | Pull up <sup>1</sup> |
| NFC_RE       | Flash read enable          | O   | 1                    |
| NFC_WE       | Flash write enable         | O   | 1                    |
| NFC_IO[15:0] | Flash data bus             | I/O | —                    |

1. Need to configure both PE and PS bit to 1'b1 of pin control register PORTC\_PCR18 to make NFC\_R/B pull up, when PTC18 is configured to MUX=6 (NFC\_R/B).

## 32.3 Memory Map/Register Definition

This section defines the NAND flash controller's registers.

### NFC memory map

| Absolute address (hex) | Register name                       | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|-------------------------------------|-----------------|--------|-------------|-----------------------------|
| 400A_BF00              | Flash command 1 (NFC_CMD1)          | 32              | R/W    | 30FF_0000h  | <a href="#">32.3.1/844</a>  |
| 400A_BF04              | Flash command 2 (NFC_CMD2)          | 32              | R/W    | 007E_E000h  | <a href="#">32.3.2/845</a>  |
| 400A_BF08              | Column address (NFC_CAR)            | 32              | R/W    | 0000_0000h  | <a href="#">32.3.3/846</a>  |
| 400A_BF0C              | Row address (NFC_RAR)               | 32              | R/W    | 1100_0000h  | <a href="#">32.3.4/846</a>  |
| 400A_BF10              | Flash command repeat (NFC_RPT)      | 32              | R/W    | 0000_0000h  | <a href="#">32.3.5/847</a>  |
| 400A_BF14              | Row address increment (NFC_RAI)     | 32              | R/W    | 0000_0001h  | <a href="#">32.3.6/848</a>  |
| 400A_BF18              | Flash status 1 (NFC_SR1)            | 32              | R      | 0000_0000h  | <a href="#">32.3.7/848</a>  |
| 400A_BF1C              | Flash status 2 (NFC_SR2)            | 32              | R      | 0000_0000h  | <a href="#">32.3.8/849</a>  |
| 400A_BF20              | DMA channel 1 address (NFC_DMA_CH1) | 32              | R/W    | 0000_0000h  | <a href="#">32.3.9/849</a>  |
| 400A_BF24              | DMA configuration (NFC_DMACFG)      | 32              | R/W    | 0000_0000h  | <a href="#">32.3.10/850</a> |
| 400A_BF28              | Cach swap (NFC_SWAP)                | 32              | R/W    | 0FFE_0FFEh  | <a href="#">32.3.11/850</a> |
| 400A_BF2C              | Sector size (NFC_SECSZ)             | 32              | R/W    | 0000_0420h  | <a href="#">32.3.12/851</a> |
| 400A_BF30              | Flash configuration (NFC_CFG)       | 32              | R/W    | 000E_A631h  | <a href="#">32.3.13/852</a> |
| 400A_BF34              | DMA channel 2 address (NFC_DMA_CH2) | 32              | R/W    | 0000_0000h  | <a href="#">32.3.14/854</a> |
| 400A_BF38              | Interrupt status (NFC_ISR)          | 32              | R/W    | 6000_0000h  | <a href="#">32.3.15/855</a> |

### 32.3.1 Flash command 1 (NFC\_CMD1)

Address: 400A\_8000h base + 3F00h offset = 400A\_BF00h

#### NFC\_CMD1 field descriptions

| Field          | Description  |
|----------------|--|
| 31–24<br>BYTE2 | Second command byte that may be sent to the flash device |

Table continues on the next page...

### NFC\_CMD1 field descriptions (continued)

| Field            | Description   |
|------------------|---|
| 23–16<br>BYTE3   | Third command byte that may be sent to the flash device                                 |
| 15–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 32.3.2 Flash command 2 (NFC\_CMD2)

Address: 400A\_8000h base + 3F04h offset = 400A\_BF04h

### NFC\_CMD2 field descriptions

| Field           | Description  |
|-----------------|--|
| 31–24<br>BYTE1  | First command byte that may be sent to the flash device  |
| 23–8<br>CODE    | User-defined flash operation sequencer<br><br>Each bit indicates a certain action. If the bit is set, the corresponding action is executed after writing 1 to START. The following are some configuration examples (other sequences are possible):<br><br>0111_1110_1110_0000 Read data (BYTE1, 5x Address, BYTE2, R/ $\bar{B}$ , read data)<br>1111_1111_1101_1000 Write page (DMA,BYTE1, 5x Address, write data, BYTE2, R/ $\bar{B}$ , BYTE3, read status)<br>0100_1110_1101_1000 Block erase (BYTE1, 3x Address, BYTE2, R/ $\bar{B}$ , BYTE3, read status)<br>0100_1000_0000_0100 Read ID (BYTE1, 1x Address, read ID)<br>0100_0000_0100_0000 Reset (BYTE1, R/ $\bar{B}$ )<br>0111_1110_0000_0000 CMD+address (BYTE1, 5xaddress)<br>1111_1111_1100_0000 Write page burst (DMA,BYTE1,5xAddress, write data, BYTE2,R/ $\bar{B}$ ) |
| 7–3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

Table continues on the next page...

### NFC\_CMD2 field descriptions (continued)

| Field           | Description  |
|-----------------|--|
| 2-1<br>BUFNO    | Internal buffer number used for this command   |
| 0<br>BUSY_START | <p>Busy indicator and start command</p> <p>This busy indicator is repeated in the NFC_ISR register.</p> <p><b>NOTE:</b> Read to this bitfield indicates BUSY whereas write indicates START.</p> <p>0 During reads, flash controller is idle and it is okay to send next command. During writes, no action.</p> <p>1 During reads, command execution is busy. During writes, start command execution.</p> |

### 32.3.3 Column address (NFC\_CAR)

Address: 400A\_8000h base + 3F08h offset = 400A\_BF08h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|-------|---|---|---|---|---|---|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9     | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | BYTE2 |    |    |    |    |    | BYTE1 |   |   |   |   |   |   |   |   |   |
| W     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0     |    |    |    |    |    | 0     |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0  | 0  | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |   |

#### NFC\_CAR field descriptions

| Field             | Description   |
|-------------------|---|
| 31-16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15-8<br>BYTE2     | Second byte of column address   |
| 7-0<br>BYTE1      | First byte of column address  |

### 32.3.4 Row address (NFC\_RAR)

Address: 400A\_8000h base + 3F0Ch offset = 400A\_BF0Ch

|       |       |    |     |     |    |    |     |     |       |    |    |    |    |    |    |    |
|-------|-------|----|-----|-----|----|----|-----|-----|-------|----|----|----|----|----|----|----|
| Bit   | 31    | 30 | 29  | 28  | 27 | 26 | 25  | 24  | 23    | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R     | 0     |    | RB1 | RB0 | 0  |    | CS1 | CS0 | BYTE3 |    |    |    |    |    |    |    |
| W     | 0     |    | 0   | 0   | 0  |    | 0   | 0   | 0     |    |    |    |    |    |    |    |
| Reset | 0     | 0  | 0   | 1   | 0  | 0  | 0   | 1   | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit   | 15    | 14 | 13  | 12  | 11 | 10 | 9   | 8   | 7     | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| R     | BYTE2 |    |     |     |    |    |     |     | BYTE1 |    |    |    |    |    |    |    |
| W     | 0     |    |     |     |    |    |     |     | 0     |    |    |    |    |    |    |    |
| Reset | 0     | 0  | 0   | 0   | 0  | 0  | 0   | 0   | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

### NFC\_RAR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–30<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 29<br>RB1         | Ready/busy 1 enable<br><br>Determines if NFC_R/ $\bar{B}$ 1 is waited on a wait for R/ $\bar{B}$ command. If an equal number of $\overline{\text{NFC\_CE}}$ and NFC_R/ $\bar{B}$ lines are used, the CS <i>n</i> and RB <i>n</i> fields must contain identical values. If only one NFC_R/ $\bar{B}$ is used, then CS <i>n</i> determines the true chip select, and this field is always 0.<br><br>0 NFC_R/ $\bar{B}$ 1 is disabled<br>1 NFC_R/ $\bar{B}$ 1 is enabled |
| 28<br>RB0         | Ready/busy 0 enable<br><br>Determines if NFC_R/ $\bar{B}$ 0 is waited on a wait for R/ $\bar{B}$ command. If an equal number of $\overline{\text{NFC\_CE}}$ and NFC_R/ $\bar{B}$ lines are used, the CS <i>n</i> and RB <i>n</i> fields must contain identical values. If only one NFC_R/ $\bar{B}$ is used, then CS <i>n</i> determines the true chip select, and this field is always 1.<br><br>0 NFC_R/ $\bar{B}$ 0 is disabled<br>1 NFC_R/ $\bar{B}$ 0 is enabled |
| 27–26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 32.3.5 Flash command repeat (NFC\_RPT)

Address: 400A\_8000h base + 3F10h offset = 400A\_BF10h

### NFC\_RPT field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 15–0<br>COUNT     | 16-bit repeat count<br><br>Determines how many times NFC_CMD2[CODE] is executed. If 0 or 1, the flash command is executed once. |

### 32.3.6 Row address increment (NFC\_RAI)

When auto-increment of row address is enabled (NFC\_CFG[AIAD] = 1), the row address is incremented as follows:

$$\text{new}\{\text{NFC\_RAR}[\text{BYTE3}, \text{BYTE2}, \text{BYTE1}]\} = \{\text{NFC\_RAR}[\text{BYTE3}], \text{NFC\_RAR}[\text{BYTE2}], \text{NFC\_RAR}[\text{BYTE1}]\} + \{\text{NFC\_RAI}[\text{INC3}, \text{INC2}, \text{INC1}]\}$$

Address: 400A\_8000h base + 3F14h offset = 400A\_BF14h

|       |    |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |      |    |   |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|------|----|----|----|------|----|---|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15   | 14 | 13 | 12 | 11   | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |
| R     | 0  |    |    |    |    |    |    |    | INC3 |    |    |    |    |    |    |    | INC2 |    |    |    | INC1 |    |   |   |   |   |   |   |   |   |   |   |   |
| W     | 0  |    |    |    |    |    |    |    | 0    |    |    |    |    |    |    |    | 0    |    |    |    | 0    |    |   |   |   |   |   |   |   |   |   |   |   |

| W     | 0   |    |    |    |    |    |    |    | 0   |    |    |    |    |    |    |    | 0   |    |    |    | 0   |    |   |   |   |   |   |   |   |   |   |   |   |
| Reset | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   | 0  | 0  | 0  | 0   | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### NFC\_SR1 field descriptions

| Field        | Description                             |
|--------------|---|
| 31–24<br>ID1 | First byte returned by read ID command  |
| 23–16<br>ID2 | Second byte returned by read ID command |
| 15–8<br>ID3  | Third byte returned by read ID command  |
| 7–0<br>ID4   | Fourth byte returned by read ID command |

### 32.3.8 Flash status 2 (NFC\_SR2)

Address: 400A\_8000h base + 3F1Ch offset = 400A\_BF1Ch

### NFC\_SR2 field descriptions

| Field            | Description   |
|------------------|---|
| 31–24<br>ID5     | Fifth byte returned by read ID command  |
| 23–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 7–0<br>STATUS1   | Byte returned by read status command  |

### 32.3.9 DMA channel 1 address (NFC\_DMA\_CH1)

Address: 400A\_8000h base + 3F20h offset = 400A\_BF20h

### NFC\_DMA\_CH1 field descriptions

| Field           | Description                                  |
|-----------------|--|
| 31–0<br>ADDRESS | DMA channel 1 address. It is 8-byte aligned. |

### 32.3.10 DMA configuration (NFC\_DMACFG)

Address: 400A\_8000h base + 3F24h offset = 400A\_BF24h

#### NFC\_DMACFG field descriptions

| Field           | Description   |
|-----------------|---|
| 31–20<br>COUNT1 | Number of bytes to be transferred by DMA channel 1. It should be multiple of 8 bytes.   |
| 19–13<br>COUNT2 | Number of bytes to be transferred by DMA channel 2. It should be multiple of 8 bytes.   |
| 12–9<br>OFFSET2 | 256-byte offset for DMA channel 2. DMA channel 2 transfer starts at this offset count x 256 bytes. For example, if OFFSET2 = 0x2, DMA channel 2 transfer starts at 0x200. |
| 8–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 1<br>ACT1       | DMA channel 1 status<br>0 Inactive<br>1 Active, and transfers to memory when triggered  |
| 0<br>ACT2       | DMA channel 2 status<br>0 Inactive<br>1 Active, and transfers to memory when triggered  |

### 32.3.11 Cach swap (NFC\_SWAP)

When DMA transfers data to/from the NFC cache (NFC SRAM buffer), or when the CPU reads or writes data to/from the NFC cache via the internal bus, all accesses that go to NFC\_SWAP[ADDR1] are directed to NFC\_SWAP[ADDR2]. Likewise, all accesses that go to NFC\_SWAP[ADDR2] are directed to NFC\_SWAP[ADDR1].

The feature allows the bad block marker in the first position of the spare area of a page. Because of the way the flash controller interleaves data and ECC bytes on flash devices with page sizes larger than 2 KB, the position of the bad block marker is shifted, and does not appear in the first position of the spare area of the page. The cache swap feature allows consistent swapping of the actual bad block line with the expected bad block line, and causes the operating system to get the bad block marker in the position where it is expected.

Address: 400A\_8000h base + 3F28h offset = 400A\_BF28h

|       |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |   |
|-------|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----|----|---|
| Bit   | 31 | 30 | 29 | 28 | 27    | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |   |
| R     | 0  |    |    |    | ADDR1 |    |    |    |    |    |    |    |    |    |    |    | 0 |
| W     | 0  |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |   |

**NFC\_SECSZ field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–13<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

*Table continues on the next page...*

### NFC\_SECSZ field descriptions (continued)

| Field        | Description  |
|--------------|--|
| 12–0<br>SIZE | <p>Size in bytes of one elementary transfer unit</p> <p>For devices with pages of 2KB and smaller, this is the physical size of the page in bytes (data bytes + ECC bytes) transferred in one page. When pages are larger than 2KB, they must be split in multiple virtual pages. In this case, the sector size is the size of the virtual page. The virtual page size is the physical size divided by the splitting factor, NFC_CFG[PAGECNT].</p> <p><b>NOTE:</b> If only a part of a page to be programmed or read, SIZE can be set to the number of affected bytes, not the page size. Then, ECC and DMA (data bytes) are all performed on the number of bytes, indicated by SIZE.</p> <p><b>NOTE:</b> For 16-bit data width flash devices, only odd SIZE is supported. If SIZE is even number, the real implemented size is SIZE – 1. So, write size + 1 to this field. For example, if SIZE = 1, no data is written or read.</p> <p><b>NOTE:</b> When programming NAND memory using the ECC feature, ensure that SIZE is equal to number of (data + ECC bytes).</p> |

### 32.3.13 Flash configuration (NFC\_CFG)

Address: 400A\_8000h base + 3F30h offset = 400A\_BF30h

|       |             |    |    |    |         |    |    |    |          |    |        |         |         |    |      |          |

## 32.4 Functional Description

The NFC executes commands on a single or bank of external NAND flash chips. The NFC supports commands such as read, program, reset, erase, status read, read ID.

The NFC block contains a DMA engine and built-in ECC logic. For each read or write, the NFC performs ECC calculations on-the-fly. Two DMA channels are organized for each read or write: one for the main area, and one for the spare area. It is possible to disable the second DMA channel, and transfer main and spare data with only the first DMA channel.

Page size supported is 512, 2K, 4K, 8K and 16K bytes. There are 8 different ECC settings provided: 0, 4, 6, 8, 12, 16, 24 and 32 bits errors. They use 0, 8, 12, 15, 23, 30, 45 and 60 ECC bytes. The ECC works on page sizes of 512+spares bytes, 1K+spares bytes, 2K+spares bytes. The ECC algorithm used is a BCH code.

The error corrector can write ECC status to the spare area, since the read is pipelined. This means, while the current page is transferred from flash to buffer, the previous page is ECC corrected, and the page before that is transferred using DMA. Because of the pipelining, it is difficult to inform the CPU in the foreground of ECC errors. To solve this, ECC status is written to the auxiliary area of the sector, and transferred to memory. See [Error Corrector Status](#) for more information. It's up to the CPU to inspect the ECC result in memory, and act appropriately.

As described, reads are pipelined. However, writes are flow-through; no advance operations are done during a write. If there is a problem found during a write, the command sequence may be interrupted, and the CPU is informed.

Each page read, page write, page erase, read ID, or read status command sequence needs CPU attention only once. The CPU needs to prepare the DMA to point to the data, write correct values to all registers, and start the command. After command completion, the NFC block may interrupt the CPU.

The block allows command repeat, which is useful for write, read and erase, and allows processing multiple pages with just one command given by the CPU. No bank interleaving is supported during command repeat.

### 32.4.1 NFC Buffer Memory Space

The next figure shows the organization of the buffer memory space in the NFC. The memory's size is  $1152 \times 64$  bit, and is separated into four buffers, each with inconspicuous physical address. For example, buffer 0's physical address is  $(0x000 + 0x20 \times i) - (0x007 + 0x20 \times i)$ .

However, when the CPU writes or reads a buffer in non-boot mode, the CPU address is continuous, since there's an address transition inside NFC: `sram_physical_addr[13:3] = {cpu_addr[11:3],cpu_addr[13:12]}`

So, in non-boot mode, the address ranges are:

**Functional Description**

- Buffer 0: 0x0000 – 0x08FF
- Buffer 1: 0x1000 – 0x18FF
- Buffer 2: 0x2000 – 0x28FF
- Buffer 3: 0x3000 – 0x38FF

**Figure 32-17. NFC Buffer Memory Space**

### 32.4.2 Error Corrector Status

The ECC engine determines if a page is correctable. If correctable, it corrects error bits, and indicates error number. Otherwise, CORFAIL bit is asserted as shown in the next table. For a bad block management strategy to work, it may be necessary for the processor to obtain this information.

The error corrector writes the status word to a byte location to the SRAM buffer, defined by NFC\_CFG[ECCAD]. It is selectable if the status is written or not with NFC\_CFG[ECCSRAM]. If the status is written to the SRAM buffer, it becomes effectively part of the flash data, and is processed like the flash data. Most likely, the status byte is written to memory as part of the page header. Once in memory, the ECC status is visible to the CPU, while CPU parses the rest of the flash header. No interrupt on error or status is available because this increases the interrupt load on the CPU. (The interrupt would be independent of the command done interrupt.) It is not possible to stop reading when ECC fails.

The organization of the status byte is shown here.

**Table 32-18. ECC Status Word**

| Field       | Definition   |
|-------------|--|
| 7           | 0 Page has been successfully corrected                 |
| CORFAIL     | 1 Page is uncorrectable                                |
| 5–0         | Number of errors that have been corrected in this page |
| ERROR_COUNT |  |

#### NOTE

The address of the ECC status byte = Buffer n's start address + NFC\_CFG[ECCAD] + 4 (n=0,1,2,3).

### 32.4.3 NFC Basic Commands

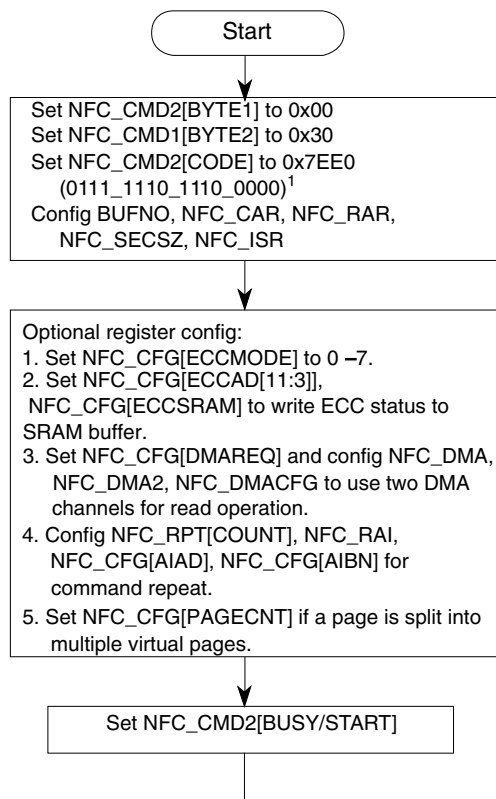

NFC basic commands include Page Read, Page Program, Block Erase, Read ID, and Reset.

#### 32.4.3.1 Page Read

This command reads pages from the NAND flash. This figure shows the general flowchart of a read operation.

## Functional Description

### Register Config

### NFC Actions

Note:

<sup>1</sup> COL\_ADDR2, NFC\_RAR[BYTE3], and NFC\_CMD1[BYTE2] (bold) are not necessary for some flash devices. See their data sheets for detail. For example:

If the flash only has one column address, then NFC\_CMD2[CODE] = 0110\_1110\_1110\_0000;

If the flash only has two row addresses, then NFC\_CMD2[CODE] = 0111\_1100\_1110\_0000;

If flash does not need the second command 0x30 for read, then NFC\_CMD2[CODE] = 0110\_1110\_0110\_0000.

**Figure 32-18. Flow Chart of Read Operation**

The next figure shows a particular case: one page is split into 8 virtual pages (see [Organization of the Data in the NAND Flash](#)), and DMA is not used. The SRAM buffer can hold data for four (virtual) pages at most. The CPU must transfer data out of the SRAM buffer after the first four virtual pages are read from flash. Otherwise, the next four virtual pages data overwrite the buffer. So, the read operation has following steps:

- Configure registers as shown in the preceding figure. NFC\_CFG[PAGECNT] = 4, start commands, wait for NFC\_ISR[DONE]
- CPU reads data from buffer, set NFC\_CMD2[CODE] = 0x20 (only enable read data)
- Start commands to read out the next 4 virtual pages, wait for NFC\_ISR[DONE]

If DMA is used to transfer data from SRAM buffer to memory instead of CPU, the flow in the preceding figure is used: set `NFC_CFG[PAGECNT] = 8`, set `NFC_CFG[DMAREQ] = 1`, configure DMA registers, start commands. A pipeline ([Functional Description](#)) controls the read operation.

Figure 32-19. Flow Chart of Read Operation, `NFC_CFG[PAGECNT] = 8`, No DMA

**Note**

See footnote in [Figure 32-18](#).

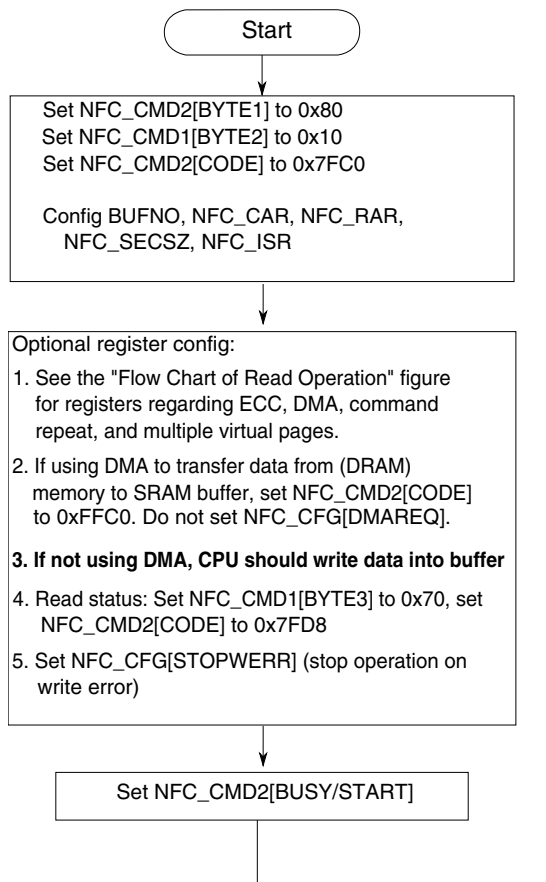

### 32.4.3.2 Page Program

This command programs pages to the NAND flash. The next figure is the general flow of page program operation.

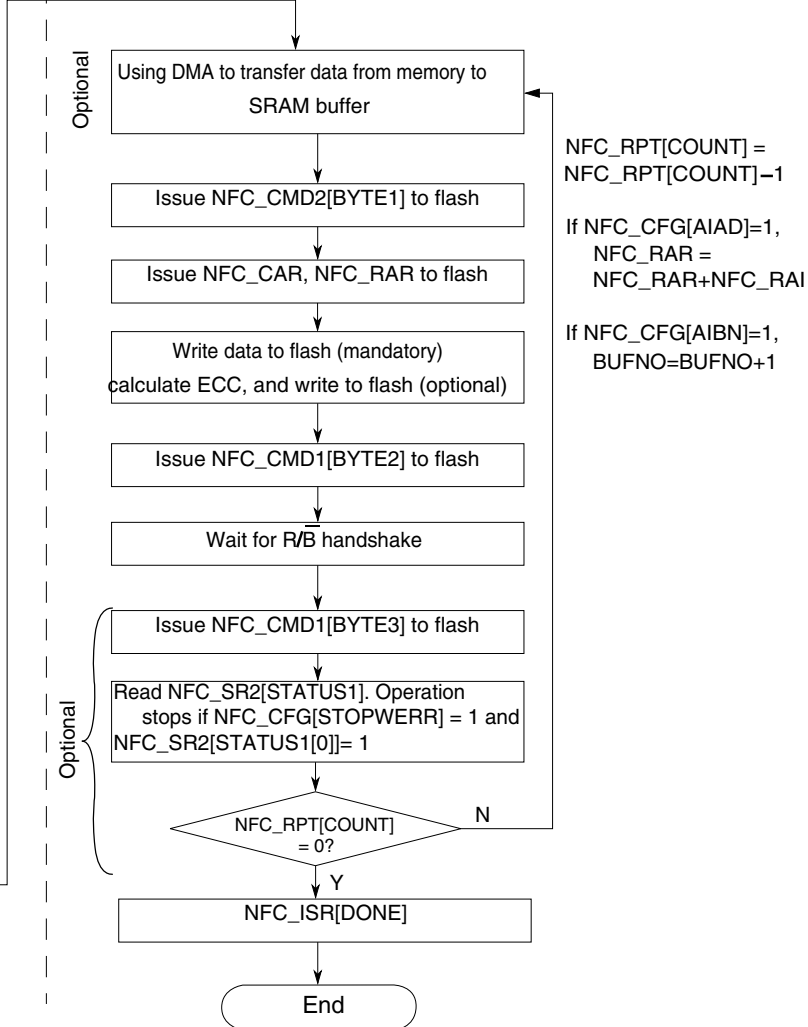

## Functional Description

### Register config

### NFC actions

**Figure 32-20. Flow Chart of Page Program Operation**

### Note

COL\_ADDR2 and NFC\_RAR[BYTE3] (bold) are not necessary for some flash devices. See their data sheets for detail. See the footnote of [Figure 32-18](#).

The next figure shows the particular case which is similar to [Figure 32-19](#). The CPU writes at most four virtual pages of data into the buffer before the first start command. Set NFC\_CFG[PAGECNT] to 4 and set NFC\_CMD2[CODE] twice:

- First, set it to 0x7F00 (0111\_1111\_0000\_0000). The NFC issues NFC\_CMD2[BYTE1], address cycles, four virtual pages data to flash. After NFC\_ISR[DONE] is set, the CPU can write the next four virtual pages data into the SRAM buffer.
- Second, set CODE to 0x01C0 (0000\_0001\_1100\_0000). The NFC sends the next four virtual pages of data to flash, issues NFC\_CMD1[BYTE2], waits for R/ $\bar{B}$  handshake, and waits for NFC\_ISR[DONE] to set.

Like the read operation, if DMA transfers data from memory to NFC SRAM buffer (instead of the CPU), the flow in the preceding figure is used and set NFC\_CFG[PAGECNT] to 0x8.

**Figure 32-21. Flow Chart of Page Program Operation, NFC\_CFG[PAGECNT] = 8, No DMA**

### Note

If you want to read the status after the second 0x10 command, set NFC\_CMD1[BYTE3] to 0x70 and NFC\_CMD2[CODE] to 0x01D8 (0000\_0001\_1101\_1000). Then, after "Wait for the R/ $\bar{B}$  handshake", the NFC issues NFC\_CMD1[BYTE3] to flash, and reads the status. If NFC\_CFG[STOPWERR] is set and NFC\_SR2[STATUS1[0]]=1, operation stops. Otherwise, NFC\_ISR[DONE] comes out. The COL\_ADDR2 and NFC\_RAR[BYTE3] of the first NFC\_CMD2[CODE] may not be necessary. See note 1 of [Figure 32-18](#).

### 32.4.3.3 Block Erase

This command is used to erase blocks.

Figure 32-22. Flow Chart of Block Erase Operation

#### Note

NFC\_RAR[BYTE3] (bold) is not necessary for some flash devices. See their data sheets for detail.

#### Note

If NFC\_CFG[STOPWERR] is set and NFC\_SR2[STATUS1[0]]=1, operation stops.

### 32.4.3.4 Read ID

This command reads the flash ID.

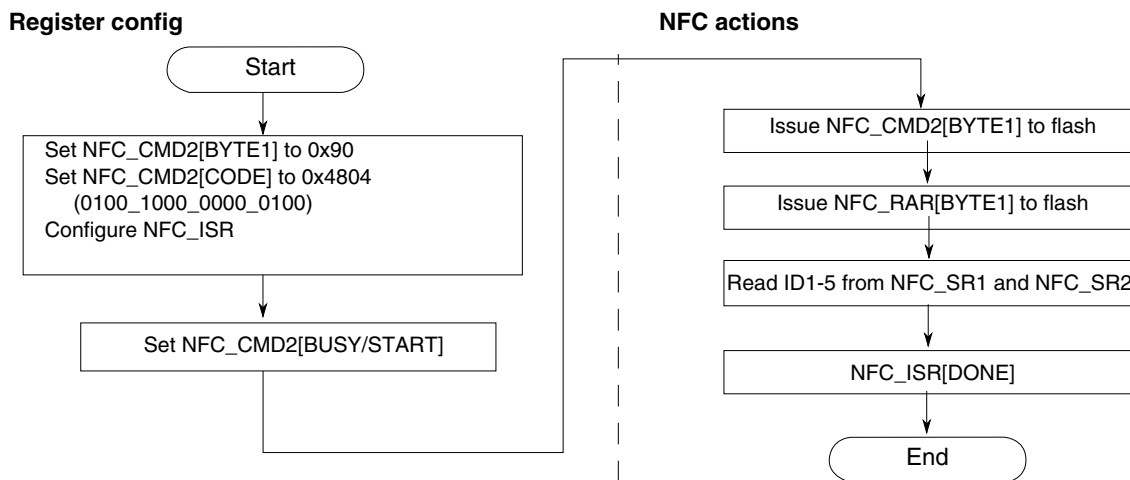

Figure 32-23. Flow Chart of Read ID Operation

### 32.4.3.5 Reset

This command sends a single reset command to the flash.

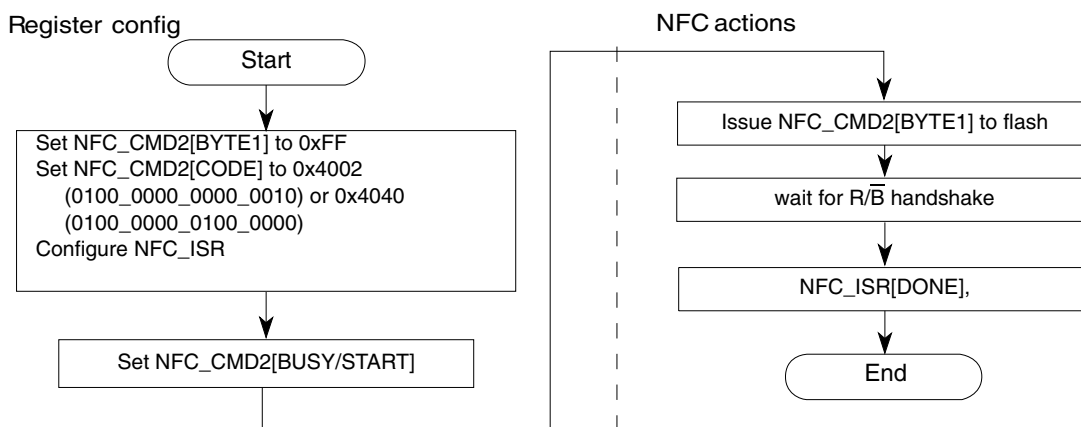

Figure 32-24. Flow Chart of Reset Operation

### 32.4.4 Fast Flash Configuration for EDO

Normally, read out data goes valid after the high-to-low transition of  $\overline{RE}$ , and invalid on the low-to-high transition (as shown in the next figure)  $t_{RHOH} < t_{REH}$ . NFC sampled the read data at the negedge of flash\_clk, and because the data is invalid at that time, a latch is used here to maintain the valid data during the high period of flash\_clk, so that NFC can sample correct data.

## Functional Description

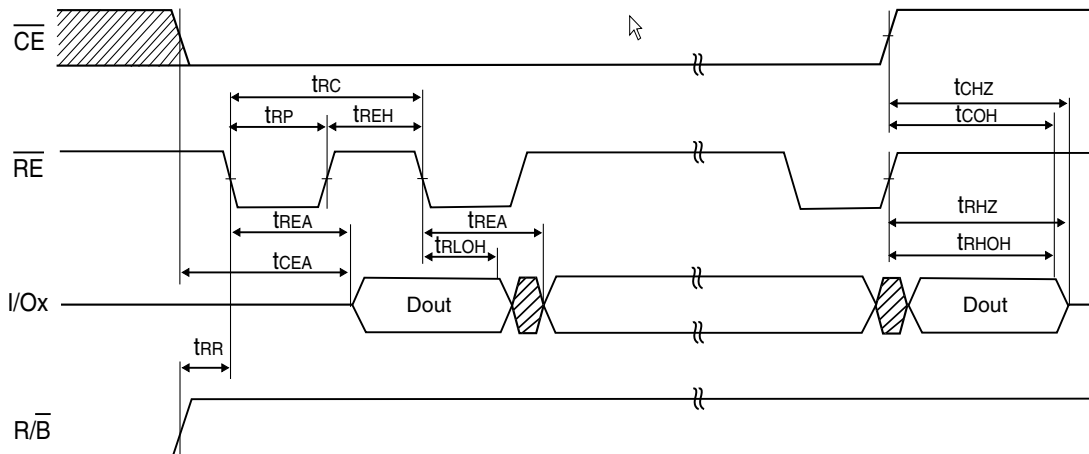

Some flash devices contain an EDO (enhanced data out) feature, where the data can be held until the next high-to-low  $\overline{RE}$  transition (see the figure after next, labeled "Read Operation, EDO type"),  $t_{RHOH} > t_{REH}$ . The read data is valid at the negedge of flash\_clk, NFC can sample data directly without latching it. To support the EDO feature, the NFC must work in fast mode (NFC\_CFG[FAST] set). The NFC clock must be configured fast enough (usually  $> 33$  MHz) according to the data sheet of flash devices.

\* Serial access Cycle after Read( $CLE=L, \overline{WE}=H, ALE=L$ )

**Figure 32-25. Read Operation**

Serial Access Cycle after Read(EDO Type,  $CLE=L, \overline{WE}=H, ALE=L$ )

**Figure 32-26. Read Operation, EDO type**

## 32.4.5 Organization of the Data in the NAND Flash

Pages on the flash can be split into multiple virtual ECC/DMA pages. The parameter that controls this is NFC\_CFG[PAGECNT]. This parameter gives the number of virtual ECC/DMA pages in one flash page.

The virtual page is split into a user (main) area and ECC (spare) area. Data in the user area can be set or used by the application, while data in the ECC area is set and used by the ECC.

The following tables give virtual-to-physical mappings for various flash devices and their recommended settings.

**Table 32-19. Virtual-to-Physical Mappings of Different Flash,**

| Flash page size (main +spare) bytes | NFC_CFG [ECC MODE] | ECC bits | NFC_CFG [PAGE CNT] | Sector size (bytes) | Virtual page user size (bytes) | Mapping   |
|-------------------------------------|--------------------|----------|--------------------|---------------------|--------------------------------|---|
| 512 + 16                            | 000                | 0        | 1                  | 528                 | 528                            | VirtualPage_0[527:0] = Physical[527:0]  |
| 512 + 16                            | 001                | 4        | 1                  | 528                 | 520                            | VirtualPage_0[519:0] = Physical[519:0]  |
| 2048 + 64                           | 000                | 0        | 1                  | 2112                | 2112                           | VirtualPage_0[2111:0] = Physical[2111:0]  |

| 4096 + 208                          | 001                | 4        | 8                  | 538                 | 530                            | VirtualPage_0[529:0] = Physical[529:0]<br>VirtualPage_1[529:0] = Physical[1067:538]<br>VirtualPage_2[529:0] = Physical[1605:1076]<br>VirtualPage_3[529:0] = Physical[2143:1614]<br>VirtualPage_4[529:0] = Physical[2681:2152]<br>VirtualPage_5[529:0] = Physical[3219:2690]<br>VirtualPage_6[529:0] = Physical[3757:3228]<br>VirtualPage_7[529:0] = Physical[4295:3766] |
| 4096 + 208                          | 010                | 6        | 8                  | 538                 | 526                            | VirtualPage_0[525:0] = Physical[525:0]<br>VirtualPage_1[525:0] = Physical[1063:538]<br>VirtualPage_2[525:0] = Physical[1601:1076]<br>VirtualPage_3[525:0] = Physical[2139:1614]<br>VirtualPage_4[525:0] = Physical[2677:2152]<br>VirtualPage_5[525:0] = Physical[3215:2690]<br>VirtualPage_6[525:0] = Physical[3753:3228]<br>VirtualPage_7[525:0] = Physical[4291:3766] |
| 4096 + 208                          | 011                | 8        | 8                  | 538                 | 523                            | VirtualPage_0[522:0] = Physical[523:0]<br>VirtualPage_1[522:0] = Physical[1060:538]<br>VirtualPage_2[522:0] = Physical[1598:1076]<br>VirtualPage_3[522:0] = Physical[2136:1614]<br>VirtualPage_4[522:0] = Physical[2674:2152]<br>VirtualPage_5[522:0] = Physical[3212:2690]<br>VirtualPage_6[522:0] = Physical[3750:3228]<br>VirtualPage_7[522:0] = Physical[4288:3766] |

1. In most applications, this mode is of no use because user size is too small.
2. When 4KB page is split into eight virtual pages, if page program/read using DMA, set NFC\_CFG[PAGECNT] to 8. if not using DMA, set NFC\_CFG[PAGECNT] to 4. See [Page Read](#) and [Page Program](#) for details.

If flash devices with a physical page size of 4K or more are used, the bad block marker appears as the first byte of the spare area. But, because of the physical-to-virtual mapping, it does not appear in byte 2048 of the virtual page, where its logical place would be. The DMA engine contains the option to swap some bytes, and to make the bad block marker appear in the requested place.

**Table 32-20. Using the Swap Field to Move the Bad Block Marker**

| Flash sector size (main + spare) bytes | Bad block marker (physical) | Bad block marker (virtual) Before swap | Bad block marker (expected) After swap | Swap  |
|--|-----------------------------|--|--|---|
| 4096 + 128                             | 4096                        | Page 1/byte 1984                       | Page 1/byte 2048                       | NFC_SWAP[ADDR1] = (1984/8) <sup>1</sup><br>NFC_SWAP[ADDR2] = (2048/8) |
| 4096 + 208                             | 4096                        | Page 1/byte 1944                       | Page 1/byte 2048                       | NFC_SWAP[ADDR1] = (1944/8)<br>NFC_SWAP[ADDR2] = (2048/8)              |

1. Only works with a user page size of at least 2055 bytes. Does not work with ECC mode 111.

### 32.4.6 Flash Command Code Description

The 16-bit command code in NFC\_CMD2[CODE] is defined in the next table. If a bit is set, the action is executed. The command is repeated for the number of the NFC\_RPT[COUNT] value. If NFC\_RPT[COUNT] is zero or one, the command is executed once.

**Table 32-21. NFC\_CMD2[CODE] Detail**

| NFC_CMD2 [CODE] bit | Action when Bit is Set  |
|---------------------|---|
| 15                  | Start DMA transfer to read data from memory , and write to SRAM.  |
| 14                  | Send command byte 1 (NFC_CMD2[BYTE1]) to flash  |
| 13                  | Send column address 1 (NFC_CAR[BYTE1]) to flash   |
| 12                  | Send column address 2 (NFC_CAR[BYTE2]) to flash   |
| 11                  | Send row address 1 (NFC_RAR[BYTE1]) to flash  |
| 10                  | Send row address 2 (NFC_RAR[BYTE2]) to flash  |
| 9                   | Send row address 3 (NFC_RAR[BYTE3]) to flash  |
| 8                   | Write data to flash. Total of NFC_CFG[PAGECNT] pages is written to the flash, and equal number of starts is sent to the residue engine. Also, additional starts to the DMA engine are sent, until DMA has transferred the NFC_CFG[PAGECNT] data from memory to NFC.           |
| 7                   | Send command byte 2 (NFC_CMD1[BYTE2]) to flash  |
| 6                   | Wait for flash R/B handshake  |
| 5                   | Read data from flash. Read is only started if the new NFC_CMD2[BUFNO] is idle. One or more starts are sent to the residue engine, total NFC_CFG[PAGECNT] starts.<br><b>Note:</b> For reads, DMA is not started. Instead, to start DMA for reads, NFC_CFG[DMAREQ] must be set. |
| 4                   | Send command byte 3 (NFC_CMD1[BYTE3]) to flash  |
| 3                   | Read flash status   |
| 2                   | Read ID   |
| 1                   | Always set. End-of-command marker used to signal done.  |
| 0                   | Reserved, must be cleared.  |

### 32.4.7 Interrupts

There are two interrupts to flag the end of a command execution:

1. The DONE interrupt, NFC\_ISR[DONE]. Use this interrupt if commands are sent back-to-back to the flash. It indicates when a new command can be dispatched. The DONE interrupt is given before the flash data is corrected and resident in memory, because the operation of the ECC engine and DMA engine is pipelined.

When the DONE interrupt tracks command completion, the software may also monitor the NFC\_ISR[ECCBUSY, DMABUSY, ECCBN, DMABN] fields.

- a. NFC\_ISR[ECCBUSY] indicates that the ECC block is still busy, and reports the buffer number the ECC block is working on in NFC\_ISR[ECCBN].
  - b. NFC\_ISR[DMABUSY] indicates that the DMA block is still busy, and reports the buffer number the DMA block is working on in NFC\_ISR[DMABN].
2. The command IDLE interrupt, NFC\_ISR[IDLE]. Use this interrupt if you want to use the data produced in the next process. The IDLE interrupt indicates all command processing has terminated, and the relevant data is now available in memory or the NFC SRAM buffer. When using back-to-back reads to the flash, use of the IDLE interrupt means the NFC does not operate at its maximum transfer speed, as ECC and DMA are now done in the foreground.

When using the DONE interrupt, transfer completion for write pages can be assumed when the DONE interrupt is received. When DONE is received for read pages, the data may still be in flight in the DMA or the ECC. To check this, the CPU should remember the buffer number (NFC\_CMD2[BUFNO]) associated with the command, and wait until the DMA and ECC are either idle, or are both busy on a different buffer number. (The ECC buffer number and the DMA buffer number fields do not match the BUFNO specified with the command.) You can check on any DONE interrupt or by polling the register.

# Chapter 33

## External Bus Interface (FlexBus)

### 33.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

#### 33.1.1 Definition

The FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:
  - External ROMs
  - Flash memories
  - Programmable logic devices
  - Other simple target (slave) devices

### 33.1.2 Features

FlexBus offers the following features:

- Six independent, user-programmable chip-select signals ( $\overline{\text{FB\_CS5}}$ – $\overline{\text{FB\_CS0}}$ )
- 8-bit, 16-bit, and 32-bit port sizes with configuration for multiplexed or nonmultiplexed address and data buses
- 8-bit, 16-bit, 32-bit, and 16-byte transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction
- Extended address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

### 33.2 Signal descriptions

This table describes the external signals involved in data-transfer operations.

**NOTE**

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

**Table 33-1. FlexBus signal descriptions**

| Signal       | I/O | Function   |
|--------------|-----|--|
| FB_A31–FB_A0 | O   | Address Bus<br>When FlexBus is used in a nonmultiplexed configuration, this is the address bus. When FlexBus is used in a multiplexed configuration, this bus is not used.   |
| FB_D31–FB_D0 | I/O | Data Bus—During the first cycle, this bus drives the upper address byte, addr[31:24].<br>When FlexBus is used in a nonmultiplexed configuration, this is the data bus, FB_D.<br>When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD.<br>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.<br>When FlexBus is used in a multiplexed configuration, the full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0. |

*Table continues on the next page...*

**Table 33-1. FlexBus signal descriptions (continued)**

| Signal  | I/O | Function   |
|---|-----|--|
| FB_CS5–FB_CS0   | O   | General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].   |
| $\overline{\text{FB\_BE}}_{31\_24}$<br>$\overline{\text{FB\_BE}}_{23\_16}$<br>$\overline{\text{FB\_BE}}_{15\_8}$<br>$\overline{\text{FB\_BE}}_{7\_0}$ | O   | Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.<br><br>For external SRAM or flash devices, the $\overline{\text{FB\_BE}}$ outputs should be connected to individual byte strobe signals.   |
| FB_OE   | O   | Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.  |
| FB_R/ $\overline{\text{W}}$   | O   | Read/Write—Indicates whether the current bus operation is a read operation (FB_R/ $\overline{\text{W}}$ high) or a write operation (FB_R/ $\overline{\text{W}}$ low).  |
| FB_TS   | O   | Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid.<br><br>An inverted $\overline{\text{FB\_TS}}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.<br><br>$\overline{\text{FB\_TS}}$ /FB_ALE is asserted for one bus clock cycle.<br><br>The chip can extend this signal until the first positive clock edge after $\overline{\text{FB\_CS}}$ asserts. See CSCR[EXTS] and <a href="#">Extended Transfer Start/Address Latch Enable</a> . |
| FB_ALE  | O   | Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS).  |

*Table continues on the next page...*

**Table 33-1. FlexBus signal descriptions (continued)**

| Signal            | I/O | Function   |
|-------------------|-----|--|
| FB_TSIZ1–FB_TSIZ0 | O   | <p>Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports.</p> <ul style="list-style-type: none"> <li>• 00b = 4 bytes</li> <li>• 01b = 1 byte</li> <li>• 10b = 2 bytes</li> <li>• 11b = 16 bytes (line)</li> </ul> <p>For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b).</p> <p>For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows:</p> <ul style="list-style-type: none"> <li>• If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size.</li> <li>• If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size.</li> </ul> <p>For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each FB_TS assertion to reflect the next transfer size.</p> <p>For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.</p> |
| FB_TBST           | O   | <p>Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size.</p> <p><b>Note:</b> When a burst transfer is in progress (<math>\overline{\text{FB\_TBST}} = 0\text{b}</math>), the transfer size is 16 bytes (FB_TSIZ1–FB_TSIZ0 = 11b), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.</p>   |

Table continues on the next page...

**Table 33-1. FlexBus signal descriptions (continued)**

| Signal         | I/O                        | Function  |
|----------------|----------------------------|---|
| FB_T $\bar{A}$ | I                          | <p>Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_T<math>\bar{A}</math> is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_T<math>\bar{A}</math> is asserted during a write transfer, the transfer is terminated.</p> <p>If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives FB_T<math>\bar{A}</math> to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), FB_T<math>\bar{A}</math> is generated internally after a specified number of wait states, or the external memory or peripheral may assert external FB_T<math>\bar{A}</math> before the wait-state countdown to terminate the transfer early. The chip deasserts FB_C<math>\bar{S}</math> one cycle after the last FB_T<math>\bar{A}</math> is asserted. During read transfers, the external memory or peripheral must continue to drive data until FB_T<math>\bar{A}</math> is recognized. For write transfers, the chip continues driving data one clock cycle after FB_C<math>\bar{S}</math> is deasserted.</p> <p>The number of wait states is determined by CSCR or the external FB_T<math>\bar{A}</math> input. If the external FB_T<math>\bar{A}</math> is used, the external memory or peripheral has complete control of the number of wait states.</p> <p><b>Note:</b> External memory or peripherals should assert FB_T<math>\bar{A}</math> only while the FB_C<math>\bar{S}</math> signal to the external memory or peripheral is asserted.</p> <p>The CSPMCR register controls muxing of FB_T<math>\bar{A}</math> with other signals. If auto-acknowledge is not used and CSPMCR does not allow FB_T<math>\bar{A}</math> control, FlexBus may hang.</p> |
| FB_CLK         | FlexBus<br>Clock<br>Output | O   |

### 33.3 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

#### Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

### FB memory map

| Absolute address (hex) | Register name  | Width (in bits) | Access | Reset value | Section/page               |

### 33.3.1 Chip Select Address Register (FB\_CSAR<sub>n</sub>)

Specifies the associated chip-select's base address.

Address: 4000\_C000h base + 0h offset + (12d × i), where i=0d to 5d

#### FB\_CSAR<sub>n</sub> field descriptions

| Field       | Description  |
|-------------|--|
| 31–16<br>BA | Base Address<br><br>Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed. |

*Table continues on the next page...*

**FB\_CSAR<sub>n</sub> field descriptions (continued)**

| Field            | Description  |
|------------------|--|
|                  | <b>NOTE:</b> Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSAR <sub>n</sub> and CSMR <sub>n</sub> registers appropriately before accessing this region. |
| 15–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

**33.3.2 Chip Select Mask Register (FB\_CSMR<sub>n</sub>)**

Specifies the address mask and allowable access types for the associated chip-select.

Address: 4000\_C000h base + 4h offset + (12d × i), where i=0d to 5d

|       |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R     | BAM |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit   | 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| R     | 0   |    |    |    |    |    |    | WP | 0  |    |    |    |    |    |    | V  |
| W     |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**FB\_CSMR<sub>n</sub> field descriptions**

| Field            | Description  |
|------------------|--|
| 31–16<br>BAM     | Base Address Mask<br>Defines the associated chip-select's block size by masking address bits.<br>0 The corresponding address bit in CSAR is used in the chip-select decode.<br>1 The corresponding address bit in CSAR is a don't care in the chip-select decode.  |
| 15–9<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 8<br>WP          | Write Protect<br>Controls write accesses to the address range in the corresponding CSAR.<br>0 Write accesses are allowed.<br>1 Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle. |
| 7–1<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 0<br>V           | Valid<br>Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select).   |

Table continues on the next page...

### FB\_CSMRn field descriptions (continued)

| Field | Description   |
|-------|---|
|       | <p><b>NOTE:</b> At reset, FB_CS0 will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.</p> <p>0 Chip-select is invalid.<br/>1 Chip-select is valid.</p> |

### 33.3.3 Chip Select Control Register (FB\_CSCRn)

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

#### NOTE

To support the global chip-select ( $\overline{\text{FB\_CS0}}$ ), the CSCR0 reset values differ from the other CSCRs. The reset value of CSCR0 is as follows:

- Bits 31–24 are 0b
- Bit 23–3 are chip-dependent
- Bits 3–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: 4000\_C000h base + 8h offset + (12d × i), where i=0d to 5d

|       |     |    |    |    |    |    |    |     |     |      |      |      |      |    |    |    |  |

### FB\_CSCRn field descriptions

| Field        | Description           |
|--------------|-----------------------|
| 31–26<br>SWS | Secondary Wait States |

Table continues on the next page...

**FB\_CSCR<sub>n</sub> field descriptions (continued)**

| Field             | Description  |
|-------------------|--|
|                   | Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS).  |
| 25–24<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 23<br>SWSEN       | Secondary Wait State Enable<br><br>0 Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers.<br>1 Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations.  |
| 22<br>EXTS        | Extended Transfer Start/Extended Address Latch Enable<br>Controls how long $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ is asserted.<br><br>0 Disabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ asserts for one bus clock cycle.<br>1 Enabled. $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ remains asserted until the first positive clock edge after $\overline{\text{FB\_CSn}}$ asserts.   |
| 21–20<br>ASET     | Address Setup<br>Controls when the chip-select is asserted with respect to assertion of a valid address and attributes.<br><br>00 Assert $\overline{\text{FB\_CSn}}$ on the first rising clock edge after the address is asserted (default for all but $\overline{\text{FB\_CS0}}$ ).<br>01 Assert $\overline{\text{FB\_CSn}}$ on the second rising clock edge after the address is asserted.<br>10 Assert $\overline{\text{FB\_CSn}}$ on the third rising clock edge after the address is asserted.<br>11 Assert $\overline{\text{FB\_CSn}}$ on the fourth rising clock edge after the address is asserted (default for $\overline{\text{FB\_CS0}}$ ).  |
| 19–18<br>RDAH     | Read Address Hold or Deselect<br>Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space.<br><br><b>NOTE:</b> <ul style="list-style-type: none"> <li>The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.</li> <li>The number of cycles the address and attributes are held after <math>\overline{\text{FB\_CSn}}</math> deassertion depends on the value of the AA bit.</li> </ul><br>00 When AA is 1b, 1 cycle. When AA is 0b, 0 cycles.<br>01 When AA is 1b, 2 cycles. When AA is 0b, 1 cycle.<br>10 When AA is 1b, 3 cycles. When AA is 0b, 2 cycles.<br>11 When AA is 1b, 4 cycles. When AA is 0b, 3 cycles. |
| 17–16<br>WRAH     | Write Address Hold or Deselect<br>Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space.<br><br><b>NOTE:</b> The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle.<br><br>00 1 cycle (default for all but $\overline{\text{FB\_CS0}}$ )<br>01 2 cycles<br>10 3 cycles<br>11 4 cycles (default for $\overline{\text{FB\_CS0}}$ )  |

Table continues on the next page...

### FB\_CSCRn field descriptions (continued)

| Field       | Description  |
|-------------|--|
| 15–10<br>WS | <p>Wait States</p> <p>Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states).</p>   |
| 9<br>BLS    | <p>Byte-Lane Shift</p> <p>Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access.</p> <p>0 Not shifted. Data is left-aligned on FB_AD.<br/>1 Shifted. Data is right-aligned on FB_AD.</p>  |
| 8<br>AA     | <p>Auto-Acknowledge Enable</p> <p>Asserts the internal transfer acknowledge for accesses specified by the chip-select address.</p> <p><b>NOTE:</b> If AA is 1b for a corresponding FB_CS<sub>n</sub> and the external system asserts an external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown asserts the internal FB_TA, the cycle is terminated. Burst cycles increment the address bus between each internal termination.</p> <p><b>NOTE:</b> This field must be 1b if CSPMCR disables FB_TA.</p> <p>0 Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally.<br/>1 Enabled. Internal transfer acknowledge is asserted as specified by WS.</p> |
| 7–6<br>PS   | <p>Port Size</p> <p>Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles.</p> <p>00 32-bit port size. Valid data is sampled and driven on FB_D[31:0].<br/>01 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b.<br/>1X 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b.</p>   |
| 5<br>BEM    | <p>Byte-Enable Mode</p> <p>Specifies whether the corresponding <math>\overline{\text{FB\_BE}}</math> is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs.</p> <p>0 <math>\overline{\text{FB\_BE}}</math> is asserted for data write only.<br/>1 <math>\overline{\text{FB\_BE}}</math> is asserted for data read and write accesses.</p>   |
| 4<br>BSTR   | <p>Burst-Read Enable</p> <p>Specifies whether burst reads are enabled for memory associated with each chip select.</p> <p>0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads.<br/>1 Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.</p>  |
| 3<br>BSTW   | <p>Burst-Write Enable</p> <p>Specifies whether burst writes are enabled for memory associated with each chip select.</p>   |

Table continues on the next page...

### FB\_CSCRn field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 0               | Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes.                        |
| 1               | Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports. |
| 2-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 33.3.4 Chip Select port Multiplexing Control Register (FB\_CSPMCR)

Controls the multiplexing of the FlexBus signals.

#### NOTE

A bus error occurs when you do any of the following:

- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.

Address: 4000\_C000h base + 60h offset = 4000\_C060h

## 33.4 Functional description

### 33.4.1 Modes of operation

FlexBus supports the following modes of operation:

- Multiplexed 32-bit address and 32-bit data
- Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
- Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- Non-multiplexed 32-bit address and 32-bit data busses

### NOTE

Some modes of operation (like 32-bit non-multiplexed address and data busses) require signals to actually be available on the pins of your specific device package. Refer to your device's signal multiplexing table to verify the availability of specific signals.

## 33.4.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

| When the transfer address                            | Then FlexBus  |
|--|---|
| Matches one address register configuration           | Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR.<br>If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle. |
| Does not match an address register configuration     | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.   |
| Matches more than one address register configuration | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.   |

## 33.4.3 Address driven on address bus

FlexBus always drives a 32-bit address on the FB\_AD bus regardless of the external memory's or peripheral's address size.

## 33.4.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
  - FB\_AD from FB\_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB\_AD from FB\_AD31 downward
  - If CSCR[BLS] = 1, FB\_AD from FB\_AD0 upward

### 33.4.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB\_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB\_AD16–FB\_AD1 and data15–data0 to FB\_AD31–FB\_AD16. See [Data-byte alignment and physical connections](#) for a graphical connection.

### 33.4.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB\_AD31–FB\_AD0)
- Control signals ( $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$ ,  $\overline{\text{FB\_TA}}$ ,  $\overline{\text{FB\_CS}}_n$ ,  $\overline{\text{FB\_OE}}$ ,  $\overline{\text{FB\_R}}/\overline{\text{W}}$ ,  $\overline{\text{FB\_BE}}_n$ )
- Attribute signals (FB\_TBST, FB\_TSIZ1–FB\_TSIZ0)

### 33.4.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB\_CLK):

- Address
- Write data
- $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$
- $\overline{\text{FB\_CS}}_n$
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

### 33.4.8 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane FB\_AD31–FB\_AD24 ( $\overline{\text{FB\_BE}}_{31\_24}$ ). A 32-bit transfer through this 8-bit port takes four transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each four-byte lane.

Figure 33-23. Connections for external memory port sizes (CSCRn[BLS] = 0)

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

Figure 33-24. Connections for external memory port sizes (CSCRn[BLS] = 1)

### 33.4.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB\_AD31–FB\_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB\_AD31–FB\_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB\_AD31–FB\_AD0 lines not used for data.

#### 33.4.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

| Port size and phase |               | FB_AD   |         |         |     |
|---------------------|---------------|---------|---------|---------|-----|
|                     |               | 31–24   | 23–16   | 15–8    | 7–0 |
| 32-bit              | Address phase | Address |         |         |     |
|                     | Data phase    | Data    |         |         |     |
| 16-bit              | Address phase | Address |         |         |     |
|                     | Data phase    | Data    |         | Address |     |
| 8-bit               | Address phase | Address |         |         |     |
|                     | Data phase    | Data    | Address |         |     |

#### 33.4.9.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

| Port size and phase |               | FB_AD   |       |      |      |
|---------------------|---------------|---------|-------|------|------|
|                     |               | 31–24   | 23–16 | 15–8 | 7–0  |
| 32-bit              | Address phase | Address |       |      |      |
|                     | Data phase    | Data    |       |      |      |
| 16-bit              | Address phase | Address |       |      |      |
|                     | Data phase    | Address |       | Data |      |
| 8-bit               | Address phase | Address |       |      |      |
|                     | Data phase    | Address |       |      | Data |

### 33.4.10 Data transfer states

Basic data transfers occur in four clocks or states. (See [Figure 33-26](#) and [Figure 33-28](#) for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

The states are described in this table.

| State | Cycle | Description   |
|-------|-------|---|
| S0    | All   | The read or write cycle is initiated. On the rising clock edge, FlexBus: <ul style="list-style-type: none"> <li>Places a valid address on FB_ADn</li> <li>Asserts <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math></li> <li>Drives FB_R/<math>\overline{\text{W}}</math> high for a read and low for a write</li> </ul>   |
| S1    | All   | FlexBus: <ul style="list-style-type: none"> <li>Negates <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math> on the rising edge of FB_CLK</li> <li>Asserts FB_CS<sub>n</sub></li> <li>Drives the data on FB_AD31– FB_AD<sub>X</sub> for writes</li> <li>Tristates FB_AD31– FB_AD<sub>X</sub> for reads</li> <li>Continues to drive the address on FB_AD pins that are unused for data</li> </ul> If the external memory or peripheral asserts $\overline{\text{FB\_TA}}$ , then the process moves to S2. If $\overline{\text{FB\_TA}}$ is not asserted internally or externally, then S1 repeats. |
|       | Read  | The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with $\overline{\text{FB\_TA}}$ asserted.  |
| S2    | All   | For internal termination, FlexBus negates FB_CS <sub>n</sub> and the transfer is complete. For external termination, the external memory or peripheral negates $\overline{\text{FB\_TA}}$ , and FlexBus negates FB_CS <sub>n</sub> after the rising edge of FB_CLK at the end of S2.  |
|       | Read  | FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.   |
| S3    | All   | FlexBus invalidates the address, data, and FB_R/ $\overline{\text{W}}$ on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.   |

### 33.4.11 FlexBus Timing Examples

#### Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

#### Note

Throughout this section:

- FB\_D[X] indicates a 32-, 16-, or 8-bit wide data bus
- FB\_A[Y] indicates an address bus that can be 32, 24, or 16 bits wide.

#### 33.4.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

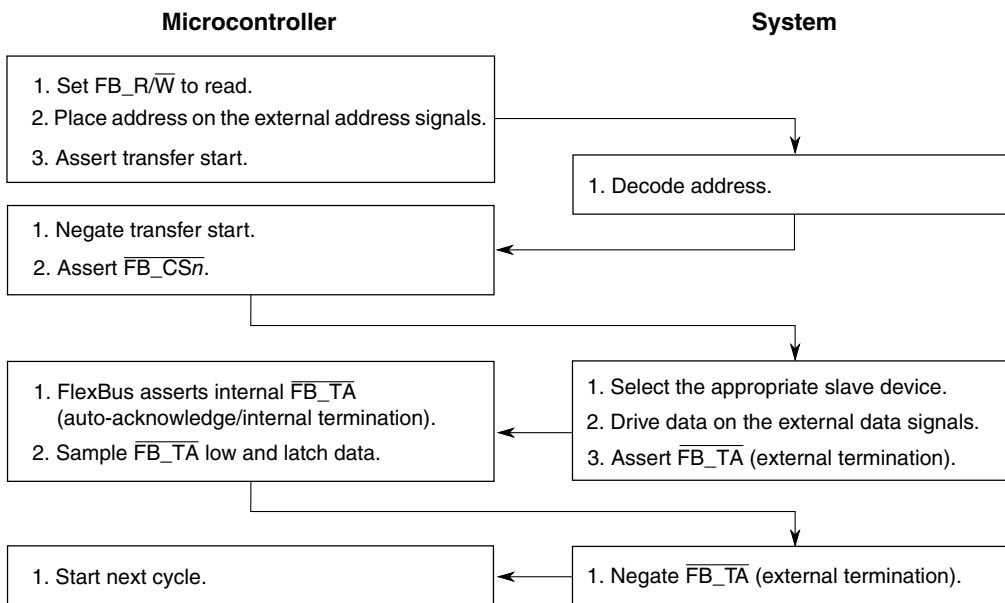

Figure 33-25. Read Cycle Flowchart

The read cycle timing diagram is shown in the following figure.

#### Note

$\overline{\text{FB\_TA}}$  does not have to be driven by the external device for internally-terminated bus cycles.

### Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

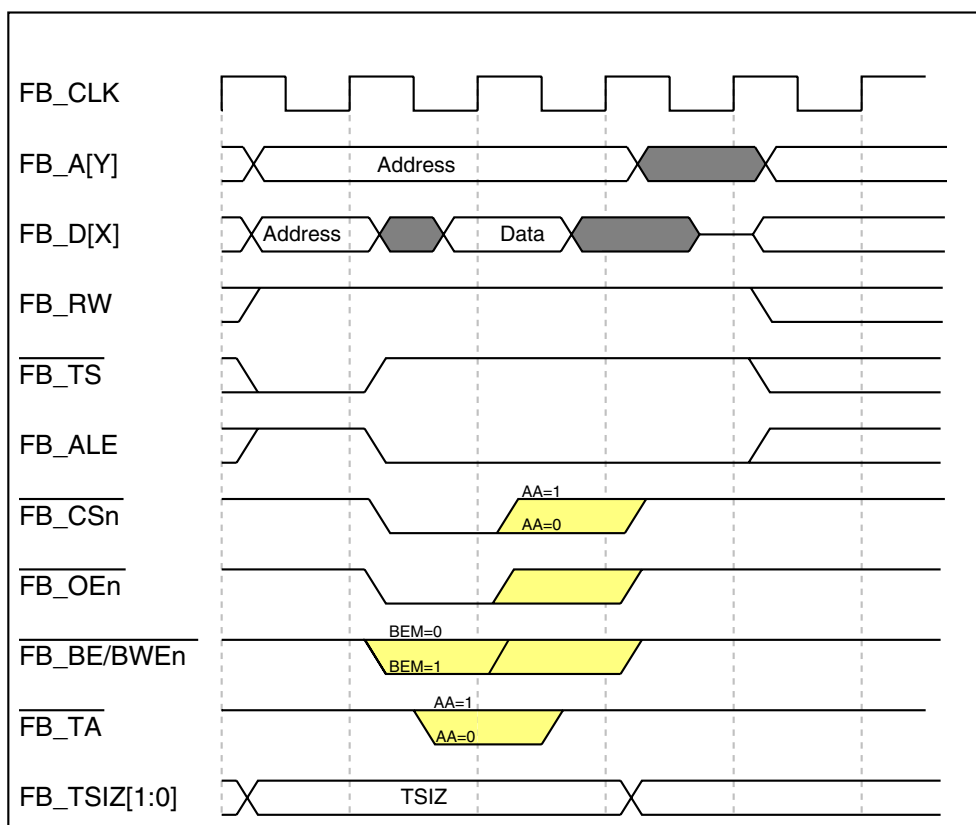

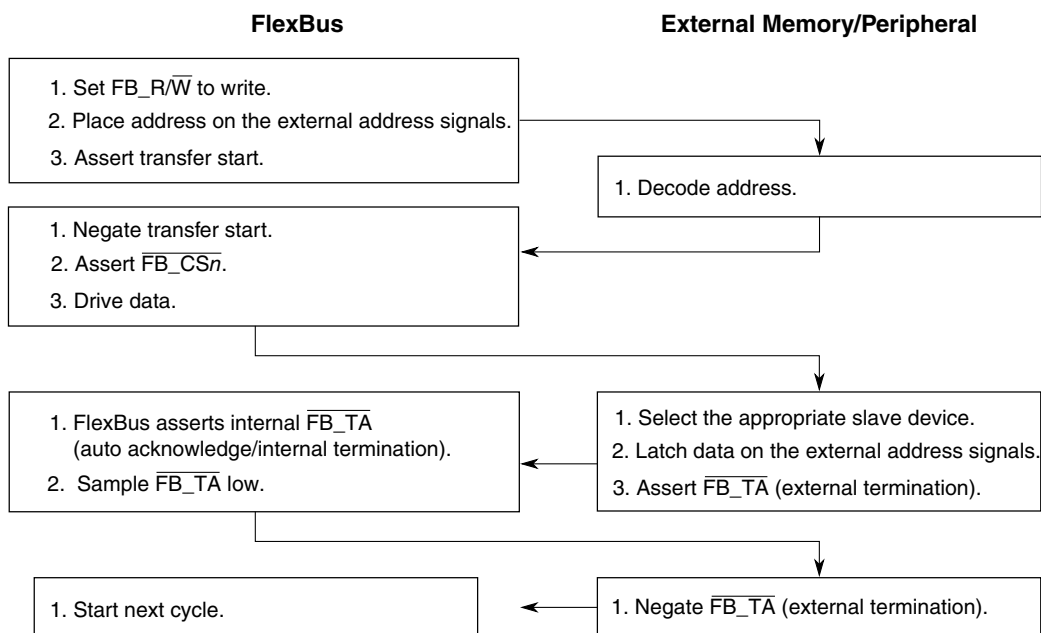

Figure 33-26. Basic Read-Bus Cycle

### 33.4.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

**Figure 33-27. Write-Cycle Flowchart**

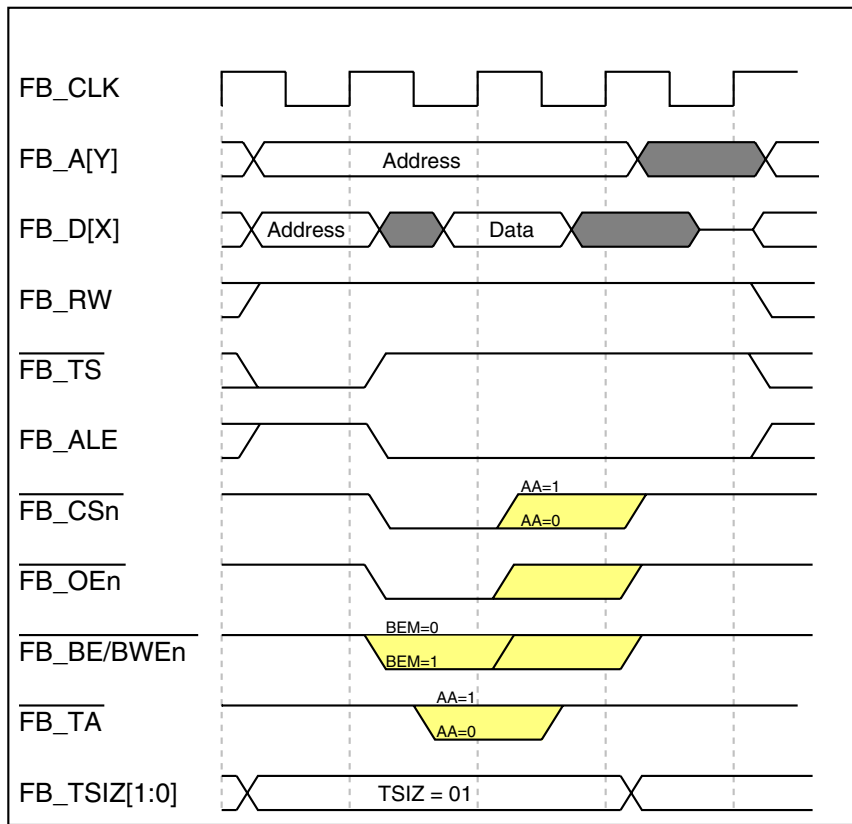

The following figure shows the write cycle timing diagram.

**Note**

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

**Figure 33-29. Single Byte-Read Transfer**

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:24].

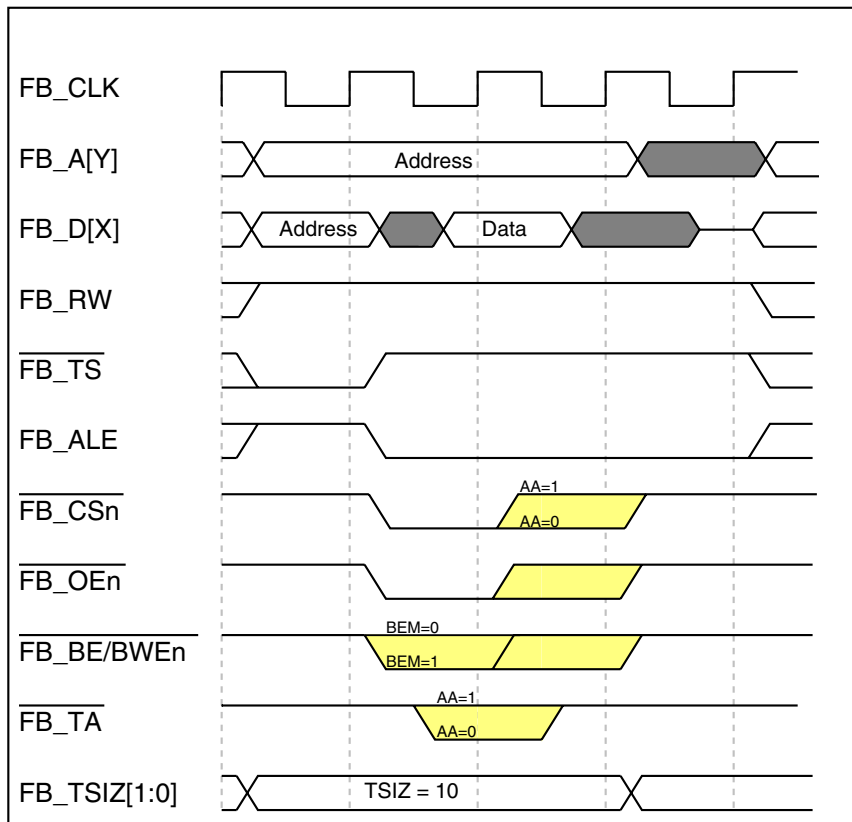

**Figure 33-30. Single Byte-Write Transfer**

### 33.4.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB\_AD[31:8] bus in the first clock.
- The device tristates FB\_AD[31:16] on the second clock and continues to drive address on FB\_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB\_AD[31:16] and may tristate the data line or continue driving the data one clock after  $\overline{\text{FB\_TA}}$  is sampled asserted.

**Figure 33-31. Single Word-Read Transfer**

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:16].

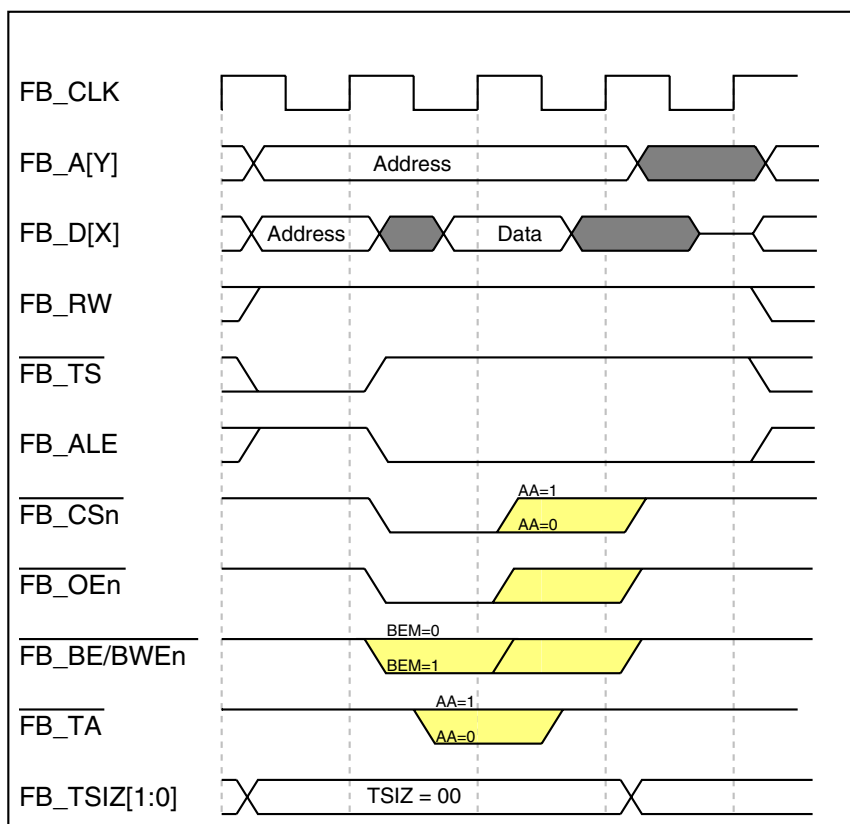

Figure 33-32. Single Word-Write Transfer

### 33.4.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The following figure depicts a longword read from a 32-bit device.

**Figure 33-33. Longword-Read Transfer**

The following figure illustrates the longword write to a 32-bit device.

**Figure 33-34. Longword-Write Transfer**

### 33.4.11.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

#### 33.4.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the  $CSCR_n$  registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in [Figure 33-26](#) and [Figure 33-31](#)) with the default of no wait states respectively.

**Figure 33-35. Basic Read-Bus Cycle (No Wait States)**

**Figure 33-36. Basic Write-Bus Cycle (No Wait States)**

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external  $\overline{\text{FB\_TA}}$  is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.

**Figure 33-37. Read-Bus Cycle (One Wait State)**

**Figure 33-38. Write-Bus Cycle (One Wait State)**

### 33.4.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable ( $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ ) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

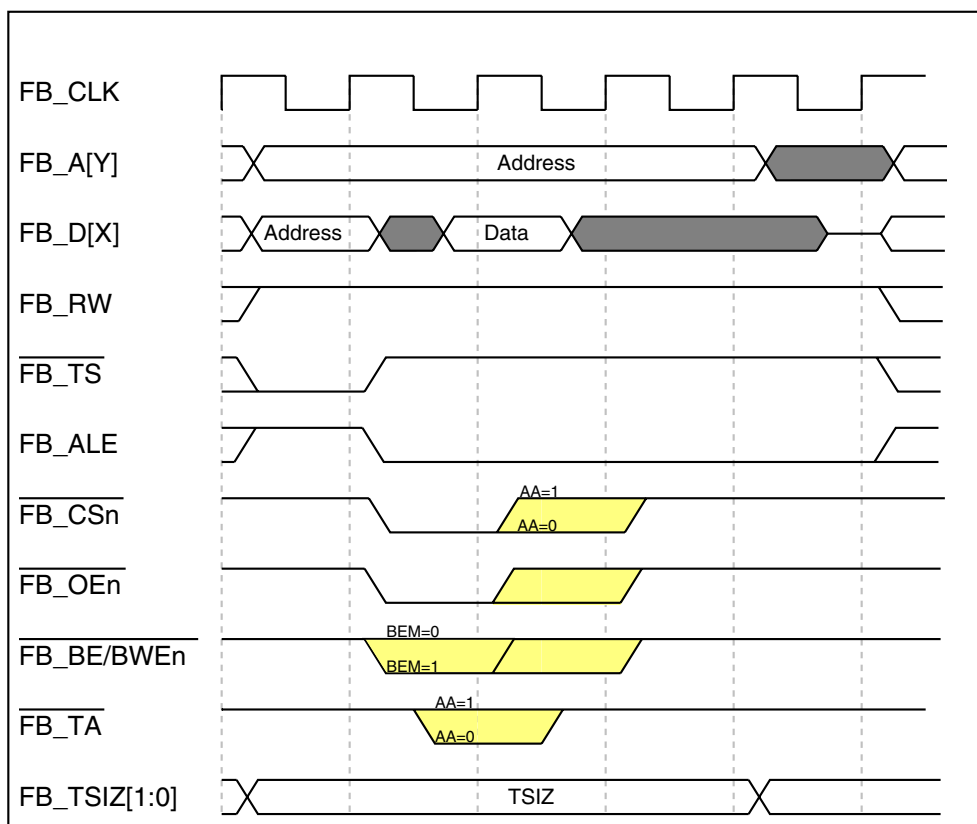

**Figure 33-39. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)**

**Figure 33-40. Write-Bus Cycle with Two Clock Address Setup (No Wait States)**

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

**Figure 33-41. Read Cycle with Two-Clock Address Hold (No Wait States)**

**Figure 33-42. Write Cycle with Two-Clock Address Hold (No Wait States)**

The following figure shows a bus cycle using address setup, wait states, and address hold.

### 33.4.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

| Port size PS[1:0] | Transfer size FB_TSIZ[1:0] | Burst-inhibited: Number of transfers |
|-------------------|----------------------------|--------------------------------------|
|                   |                            | Burst enabled: Number of beats       |
| 01b (8 bit)       | 10b (16 bits)              | 2                                    |
|                   | 00b (32 bits)              | 4                                    |
|                   | 11b (16 bytes)             | 16                                   |
| 1Xb (16 bit)      | 00b (32 bits)              | 2                                    |
|                   | 11b (16 bytes)             | 8                                    |
| 00b (32 bit)      | 11b (line)                 | 4                                    |

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

### 33.4.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

#### Note

In non-multiplexed address/data mode, the address on FB\_A increments only during internally-terminated burst cycles. The first address is driven throughout the entire burst for externally-terminated cycles.

In multiplexed address/data mode, the address is driven on FB\_AD only during the first cycle for all terminated cycles.

### 33.4.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

#### Note

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCRn[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.

### 33.4.12.5 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

### 33.4.12.6 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

#### Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSEN] = 1b) determines the number of wait states.

### 33.4.12.7 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

### 33.4.12.8 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

#### Note

In non-multiplexed address/data mode, the address on FB\_A increments only during internally-terminated burst cycles (CSCRn[AA] = 1b). The attached device must be able to account for this, or a wait state must be added. The first address is driven throughout the entire burst for externally-terminated cycles.

In multiplexed address/data mode, the address is driven on FB\_AD only during the first cycle for internally- and externally-terminated cycles.

### 33.4.12.9 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

### 33.4.13 Extended Transfer Start/Address Latch Enable

The  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts for a single bus clock cycle. When  $\text{CSCR}_n[\text{EXTS}]$  is set, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts and remain asserted until the first positive clock edge after  $\overline{\text{FB\_CS}}_n$  asserts. See the following figure.

#### NOTE

When EXTS is set,  $\text{CSCR}_n[\text{WS}]$  must be programmed to have at least one primary wait state.

Figure 33-44. Read-Bus Cycle with CSCRn[EXTS] = 1 (One Wait State)

### 33.4.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, the transfer can be terminated by asserting  $\overline{\text{FB\_TA}}$ . If the processor must manage a bus error differently, asserting an interrupt to the core along with  $\overline{\text{FB\_TA}}$  when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for  $\overline{\text{FB\_TA}}$ .

## 33.5 Initialization/Application Information

### 33.5.1 Initializing a chip-select

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

### 33.5.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

## Chapter 34

# Cyclic Redundancy Check (CRC)

### 34.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial, WAS, and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

#### 34.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or byte-wise. This option is required for certain CRC standards. A byte-wise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the byte-wise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

#### 34.1.2 Block diagram

The following is a block diagram of the CRC.

Figure 34-1. Programmable cyclic redundancy check (CRC) block diagram

### 34.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

#### 34.1.3.1 Run mode

This is the basic mode of operation.

#### 34.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

## 34.2 Memory map and register descriptions

### CRC memory map

| Absolute address (hex) | Register name                       | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|-------------------------------------|-----------------|--------|-------------|----------------------------|
| 4003_2000              | CRC Data register (CRC_DATA)        | 32              | R/W    | FFFF_FFFFh  | <a href="#">34.2.1/921</a> |
| 4003_2004              | CRC Polynomial register (CRC_GPOLY) | 32              | R/W    | 0000_1021h  | <a href="#">34.2.2/922</a> |
| 4003_2008              | CRC Control register (CRC_CTRL)     | 32              | R/W    | 0000_0000h  | <a href="#">34.2.3/922</a> |

### 34.2.1 CRC Data register (CRC\_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003\_2000h base + 0h offset = 4003\_2000h

#### CRC\_DATA field descriptions

| Field       | Description   |
|-------------|---|
| 31–24<br>HU | CRC High Upper Byte<br><br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 23–16<br>HL | CRC High Lower Byte<br><br>In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes. |
| 15–8<br>LU  | CRC Low Upper Byte<br><br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.  |
| 7–0<br>LL   | CRC Low Lower Byte<br><br>When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.  |

### 34.2.2 CRC Polynomial register (CRC\_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 4003\_2000h base + 4h offset = 4003\_2004h

#### CRC\_GPOLY field descriptions

| Field         | Description  |
|---------------|--|
| 31–16<br>HIGH | High Polynominal Half-word<br><br>Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0). |
| 15–0<br>LOW   | Low Polynominal Half-word<br><br>Writable and readable in both 32-bit and 16-bit CRC modes.  |

### 34.2.3 CRC Control register (CRC\_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

Address: 4003\_2000h base + 8h offset = 4003\_2008h

### CRC\_CTRL field descriptions

| Field            | Description  |
|------------------|--|
| 31–30<br>TOT     | <p>Type Of Transpose For Writes</p> <p>Defines the transpose configuration of the data written to the CRC data register. See the description of the transpose feature for the available transpose options.</p> <p>00 No transposition.<br/>01 Bits in bytes are transposed; bytes are not transposed.<br/>10 Both bits in bytes and bytes are transposed.<br/>11 Only bytes are transposed; no bits in a byte are transposed.</p>  |
| 29–28<br>TOTR    | <p>Type Of Transpose For Read</p> <p>Identifies the transpose configuration of the value read from the CRC Data register. See the description of the transpose feature for the available transpose options.</p> <p>00 No transposition.<br/>01 Bits in bytes are transposed; bytes are not transposed.<br/>10 Both bits in bytes and bytes are transposed.<br/>11 Only bytes are transposed; no bits in a byte are transposed.</p> |
| 27<br>Reserved   | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 26<br>FXOR       | <p>Complement Read Of CRC Data Register</p> <p>Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data.</p> <p>0 No XOR on reading.<br/>1 Invert or complement the read value of the CRC Data register.</p>  |
| 25<br>WAS        | <p>Write CRC Data Register As Seed</p> <p>When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation.</p> <p>0 Writes to the CRC data register are data values.<br/>1 Writes to the CRC data register are seed values.</p>   |
| 24<br>TCRC       | <p>Width of CRC protocol.</p> <p>0 16-bit CRC protocol.<br/>1 32-bit CRC protocol.</p>   |
| 23–0<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |

## 34.3 Functional description

### 34.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program `CRC_CTRL[WAS]`, `CRC_GPOLY`, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting `CRC_CTRL[WAS]` enables the programming of the seed value into the `CRC_DATA` register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting `CRC_CTRL[WAS]` and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

### 34.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

#### 34.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear `CRC_CTRL[TCRC]` to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 16-bit polynomial to the `CRC_GPOLY[LOW]` field. The `CRC_GPOLY[HIGH]` field is not usable in 16-bit CRC mode.
4. Set `CRC_CTRL[WAS]` to program the seed value.
5. Write a 16-bit seed to `CRC_DATA[LU:LL]`. `CRC_DATA[HU:HL]` are not used.
6. Clear `CRC_CTRL[WAS]` to start writing data values.
7. Write data values into `CRC_DATA[HU:HL:LU:LL]`. A CRC is computed on every data value write, and the intermediate CRC result is stored back into `CRC_DATA[LU:LL]`.
8. When all values have been written, read the final CRC result from `CRC_DATA[LU:LL]`.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

### 34.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set `CRC_CTRL[TCRC]` to enable 32-bit CRC mode.
2. Program the transpose and complement options in the `CTRL` register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 32-bit polynomial to `CRC_GPOLY[HIGH:LOW]`.
4. Set `CRC_CTRL[WAS]` to program the seed value.
5. Write a 32-bit seed to `CRC_DATA[HU:HL:LU:LL]`.
6. Clear `CRC_CTRL[WAS]` to start writing data values.
7. Write data values into `CRC_DATA[HU:HL:LU:LL]`. A CRC is computed on every data value write, and the intermediate CRC result is stored back into `CRC_DATA[HU:HL:LU:LL]`.
8. When all values have been written, read the final CRC result from `CRC_DATA[HU:HL:LU:LL]`. The CRC is calculated bitwise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

### 34.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

#### 34.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the `CTRL[TOT]` or `CTRL[TOTR]` fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. `CTRL[TOT]` or `CTRL[TOTR]` is 00.

functional description

No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

Bits in a byte are transposed, while bytes are not transposed.

reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

**Figure 34-5. Transpose type 01**

3. CTRL[TOT] or CTRL[TOTR] is 10.

Both bits in bytes and bytes are transposed.

reg[31:0] becomes = {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}

**Figure 34-6. Transpose type 10**

4. CTRL[TOT] or CTRL[TOTR] is 11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

**Figure 34-7. Transpose type 11**

**NOTE**

For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only. When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[**HU:HL**] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

### 34.3.4 CRC result complement

When CTRL[**FXOR**] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[**FXOR**] is cleared, reading the CRC data register accesses the raw checksum value.

# Chapter 35

## Cryptographic Acceleration Unit (CAU)

### 35.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The memory-mapped Cryptographic Acceleration Unit (CAU) is a coprocessor that is connected to the processor's Private Peripheral Bus (PPB). It supports the hardware implementation of a set of specialized operations to improve the throughput of software-based security encryption/decryption operations and message digest functions.

The CAU supports acceleration of the DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms. Freescale provides an optimized C-function library that provides the appropriate software building blocks to implement higher-level security functions.

### 35.2 CAU Block Diagram

A simplified block diagram is given below that illustrates the CAU and a table to show its parts.

Figure 35-1. CAU block diagram

Table 35-1. CAU parts table

| Item                 | Description   |
|----------------------|---|
| Translator submodule | Provides the bridge between the PPB interface and the CAU module. Passes memory-mapped commands and data on the PPB to/from the CAU |
| 4-entry FIFO         | Contains commands and input operands and the associated control captured from the PPB and sent to the CAU                           |
| CAU                  | 3-terminal block with a command and optional input operand and a result bus. More details in following figure.                      |

The following figure shows the CAU block in more detail.

**Figure 35-2. Top-level CAU block diagram**

### 35.3 Overview

As the name suggests, the CAU provides a mechanism for memory-mapped register reads and writes to be transformed into specific commands and operands sent to the CAU coprocessor.

The CAU translator module performs the following functions:

- All the required functions affecting the transmission of commands to the CAU module.
- If needed, stalling the PPB transactions based on the state of the 4-entry command/data FIFO.
- Some basic integrity checks on PPB operations.

The set of implemented algorithms provides excellent support for network security standards, such as SSL and IPsec. Additionally, using the CAU efficiently permits the implementation of any higher level functions or modes of operation, such as HMAC, CBC, and so on based on the supported algorithms.

The cryptographic algorithms are implemented partially in software with only functions critical to increasing performance implemented in hardware. The CAU allows for efficient, fine-grained partitioning of functions between hardware and software:

- Implement the innermost security kernel functions using the coprocessor instructions.
- Implement higher level functions in software by using the standard processor instructions.

This partitioning of functions is key to minimizing size of the CAU while maintaining a high level of throughput. Using software for some functions also simplifies the CAU design. The CAU implements a set of coprocessor commands that operate on a register file of 32-bit registers.

### 35.4 Features

The CAU includes the following distinctive features:

- Supports DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms
- Simple, flexible programming model
- Ability to send up to three commands in one data write operation

### 35.5 Memory map/Register definition

The CAU contains multiple registers used by each of the supported algorithms. The following table shows registers that are applicable to each supported algorithm and indicates the corresponding letter designations for each algorithm.

For more information on these letter designations, see the supported algorithm specifications.

| Code | Register                         | DES | AES | MD5 | SHA-1 | SHA-256 |
|------|----------------------------------|-----|-----|-----|-------|---------|
| 0    | CAU Status Register (CASR)       | —   | —   | —   | —     | —       |
| 1    | CAU Accumulator (CAA)            | —   | —   | a   | T     | T       |
| 2    | General-Purpose Register 0 (CA0) | C   | W0  | —   | A     | A       |
| 3    | General-Purpose Register 1 (CA1) | D   | W1  | b   | B     | B       |

Table continues on the next page...

| Code | Register                         | DES | AES | MD5 | SHA-1 | SHA-256          |
|------|----------------------------------|-----|-----|-----|-------|------------------|
| 4    | General-Purpose Register 2 (CA2) | L   | W2  | c   | C     | C                |
| 5    | General-Purpose Register 3 (CA3) | R   | W3  | d   | D     | D                |
| 6    | General-Purpose Register 4 (CA4) | —   | —   | —   | E     | E                |
| 7    | General-Purpose Register 5 (CA5) | —   | —   | —   | W     | F                |
| 8    | General-Purpose Register 6 (CA6) | —   | —   | —   | —     | G                |
| 9    | General-Purpose Register 7 (CA7) | —   | —   | —   | —     | H                |
| 10   | General-Purpose Register 8 (CA8) | —   | —   | —   | —     | W/T <sub>1</sub> |

The CAU supports only 32-bit operations and register accesses. All registers support read, write, and ALU operations. However, only bits 1–0 of the CASR are writable. Bits 31–2 of the CASR must be written as 0 for compatibility with future versions of the CAU.

The codes listed in this section are used in the memory-mapped commands. For more details on this, see [CAU programming model](#).

### NOTE

In the following table, the "address" or "offset" refers to the command code value for the CAU registers.

### CAU memory map

| Absolute address (hex) | Register name              | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|----------------------------|-----------------|--------|-------------|----------------------------|
| E008_1000              | Status Register (CAU_CASR) | 32              | R/W    | 2000_0000h  | <a href="#">35.5.1/934</a> |
| E008_1001              | Accumulator (CAU_CAA)      | 32              | R/W    | 0000_0000h  | <a href="#">35.5.2/935</a> |

| R     | 0        |    |    |    |    |    |    |    |    |    |    |    |    |    |    | DPE | IC |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   |    |

#### CAU\_CASR field descriptions

| Field            | Description  |
|------------------|--|
| 31–28<br>VER     | CAU Version<br>Indicates CAU version.<br><br>0x1 Initial CAU version.<br>0x2 Second version, added support for SHA-256 algorithm (This is the value on this device). |
| 27–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 1<br>DPE         | DES Parity Error<br>Indicates whether the DES parity error is detected.<br><br>0 No error detected.<br>1 DES key parity error detected.                              |

Table continues on the next page...

### CAU\_CASR field descriptions (continued)

| Field   | Description  |
|---------|--|
| 0<br>IC | Illegal Command<br><br>Indicates an illegal instruction has been executed.<br><br>0 No illegal commands issued.<br>1 Illegal command issued. |

### 35.5.2 Accumulator (CAU\_CAA)

Commands use the CAU accumulator for storage of results and as an operand for the cryptographic algorithms.

Address: E008\_1000h base + 1h offset = E008\_1001h

#### CAU\_CAA field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>ACC | Accumulator<br><br>Stores results of various CAU commands. |

### 35.5.3 General Purpose Register (CAU\_CAn)

The General Purpose Register is used in the CAU commands for storage of results and as operands for various cryptographic algorithms.

Address: E008\_1000h base + 2h offset + (1d × i), where i=0d to 8d

#### CAU\_CAn field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>CAn | General Purpose Registers<br><br>Used by the CAU commands. Some cryptographic operations work with specific registers. |

## 35.6 Functional description

This section discusses the programming model and operation of the CAU.

### 35.6.1 CAU programming model

The 4-entry FIFO is indirectly mapped into a 4-KB address space associated with the CAU located on this device. This address space is effectively split into two equal regions:

- one used to directly write commands for CAU load operations
- the other used to send commands and input operands for CAU loads

Data writes on the PPB are loaded into this FIFO and automatically converted into CAU load operands by the CAU translator. Data reads on the PPB are converted into CAU store register operations where the result is returned to the processor as the read data value.

The CAU requires a 15-bit command, and optionally, a 32-bit input operand, for each CAU load, PPB write. The 15-bit command includes the 9-bit opcode and other bits statically formed by the CAU translator logic controlling the CAU.

The following figure shows the 4-KB address space and the mapping of the CAU commands in this space.

#### NOTE

- Although the indirect store/load portion of the address space in the figure below shows only the indirect load/store commands, direct load commands can also be used in this space. However, it is more efficient to use the direct load portion of the address space.
- Accesses to the reserved space in the direct load space are terminated with an error, while accesses to the reserved space in the indirect load/store space are detected as an illegal CAU command. See [CAU integrity checks](#) for details.

### 35.6.1.2 Indirect loads

For CAU load operations requiring a 32-bit input operand, the address contains the 9-bit opcode to be passed to the CAU while the data is the 32-bit operand. Specifically, the CAU address and data for these indirect writes is shown in the figure below.

**Figure 35-17. Indirect loads**

### 35.6.1.3 Indirect stores

For CAU store operations, a PPB read is performed with the appropriate CAU store register opcode embedded in the address. This appears as another indirect command. The detail of Indirect stores is shown in the figure below.

**Figure 35-18. Indirect store**

## 35.6.2 CAU integrity checks

If an illegal operation or access is attempted, the PPB bus cycle is terminated with an error response and the operation is aborted and not sent to the CAU.

The CAU performs a series of address and data integrity checks as described in the following sections. The results of these checks are logically summed together and, if appropriate, a PPB error termination is generated.

### 35.6.2.1 Address integrity checks

The CAU address checking includes the following. See [Figure 35-15](#) for the CAU memory map details.

- Any CAU reference using a non-0-modulo-4 byte address ( $\text{addr}[1:0] \neq 00$ ) generates an error termination.
- For CAU writes:
  - Only the first 64 bytes of the 2-KB direct write address space can be referenced. Attempting to access regions beyond the first 64 bytes terminates with an error.
  - The second 2-KB space defines the indirect address-as-command region and any reference in this space is allowed by the CAU.

### NOTE

The CAU contains error logic to detect any illegal command sent to it. Accordingly, there are address values in this upper 2-KB region of the address space that are passed to the CAU, and then detected as illegal commands. If the CAU detects an illegal command, it sets the CASR[IC] flag and performs no operation.

- For CAU reads:
  - Any attempted read from the first 2-KB region of the address space (an attempted direct read) is illegal and produces an error termination.
  - Within the second 2-KB region of the address space, i.e.,  $\text{addr}[11] = 1$ , only a 64-byte space is treated as a legal CAU store operation. The allowable addresses are defined as:

$$\text{addr}[11:0] = 1000\_10\text{xx\_xx\_}00$$

where the 4-bit xxxx value specifies the CAU register number. The CAU supports a subset of the allowable register numbers, 0x0 - 0xA. Attempting a store of a reserved register produces an undefined result.

### 35.6.2.2 Data integrity checks

Direct writes can send 1, 2, or 3 commands to the CAU in a single 32-bit transfer. As shown in [Figure 35-16](#), the commands include a valid bit located at bits 31, 20, and 9 of the write data where:

- Bit 31 is the valid bit for the first command
- Bit 20 is the valid bit for the second command
- Bit 9 is the valid bit for the third command

The direct write data check validates the combination of these three valid bits. The following table presents the three legal states associated with these bits:

functional description

| Value of bits 31, 20, and 9 | Number of commands included |
|-----------------------------|-----------------------------|
| 100                         | 1                           |
| 110                         | 2                           |
| 111                         | 3                           |

All other combinations of bits 31, 20, and 9 are illegal and generate an error termination.

### 35.6.3 CAU commands

The CAU supports the commands shown in the following table. All other encodings are reserved. The CASR[IC] bit is set if an undefined command is issued. A specific illegal command (ILL) is defined to allow software self-checking. Reserved commands must not be issued so as to ensure compatibility with future implementations.

The CMD field specifies the 9-bit CAU opcode for the operation command.

See [Assembler equate values](#) for a set of assembly constants used in the command descriptions here. If supported by the assembler, macros can also be created for each instruction. The value CAx should be interpreted as any CAU register (CASR, CAA, and CA<sub>n</sub>).

**Table 35-15. CAU commands**

| Type           | Command name | Description       | CMD   |   |   |     |   |   |   |   |   | Operation  |
|----------------|--------------|-------------------|-------|---|---|-----|---|---|---|---|---|--|
|                |              |                   | 8     | 7 | 6 | 5   | 4 | 3 | 2 | 1 | 0 |  |
| Direct load    | CNOP         | No Operation      | 0x000 |   |   |     |   |   |   |   |   | —  |
| Indirect load  | LDR          | Load Reg          | 0x01  |   |   | CAx |   |   |   |   |   | Op1 → CAx  |
| Indirect store | STR          | Store Reg         | 0x02  |   |   | CAx |   |   |   |   |   | CAx → Result   |
| Indirect load  | ADR          | Add               | 0x03  |   |   | CAx |   |   |   |   |   | CAx + Op1 → CAx  |
| Indirect load  | RADR         | Reverse and Add   | 0x04  |   |   | CAx |   |   |   |   |   | CAx + ByteRev(Op1) → CAx                                 |
| Direct load    | ADRA         | Add Reg to Acc    | 0x05  |   |   | CAx |   |   |   |   |   | CAx + CAA → CAA  |
| Indirect load  | XOR          | Exclusive Or      | 0x06  |   |   | CAx |   |   |   |   |   | CAx ^ Op1 → CAx  |
| Indirect load  | ROTL         | Rotate Left       | 0x07  |   |   | CAx |   |   |   |   |   | (CAx <<< (Op1 % 32))   (CAx >>> (32 - (Op1 % 32))) → CAx |
| Direct load    | MVRA         | Move Reg to Acc   | 0x08  |   |   | CAx |   |   |   |   |   | CAx → CAA  |
| Direct load    | MVAR         | Move Acc to Reg   | 0x09  |   |   | CAx |   |   |   |   |   | CAA → CAx  |
| Direct load    | AESS         | AES Sub Bytes     | 0x0A  |   |   | CAx |   |   |   |   |   | SubBytes(CAx) → CAx                                      |
| Direct load    | AESIS        | AES Inv Sub Bytes | 0x0B  |   |   | CAx |   |   |   |   |   | InvSubBytes(CAx) → CAx                                   |
| Indirect load  | AESC         | AES Column Op     | 0x0C  |   |   | CAx |   |   |   |   |   | MixColumns(CAx)^Op1 → CAx                                |
| Indirect load  | AESIC        | AES Inv Column Op | 0x0D  |   |   | CAx |   |   |   |   |   | InvMixColumns(CAx^Op1) → CAx                             |

Table continues on the next page...

**Table 35-15. CAU commands (continued)**

| Type        | Command name | Description          | CMD   |   |   |    |         |         |    |                            | Operation  |
|-------------|--------------|----------------------|-------|---|---|----|---------|---------|----|----------------------------|--|
|             |              |                      | 8     | 7 | 6 | 5  | 4       | 3       | 2  | 1                          |  |
| Direct load | AESR         | AES Shift Rows       | 0x0E0 |   |   |    |         |         |    |                            | ShiftRows(CA0-CA3) → CA0-CA3   |
| Direct load | AESIR        | AES Inv Shift Rows   | 0x0F0 |   |   |    |         |         |    |                            | InvShiftRows(CA0-CA3)→CA0-CA3  |
| Direct load | DESR         | DES Round            | 0x10  |   |   | IP | FP      | KS[1:0] |    |                            | DES Round(CA0-CA3)→CA0-CA3   |
| Direct load | DESK         | DES Key Setup        | 0x11  |   |   | 0  | 0       | CP      | DC |                            | DES Key Op(CA0-CA1)→CA0-CA1<br>Key Parity Error & CP →CASR[1]  |

| Direct load | ILL          | Illegal Command      | 0x1F0 |   |   |    |         |         |    |                            | 0x1 → CASR[IC]   |

### 35.6.3.1 Coprocessor No Operation (CNOP)

The CNOP command is the coprocessor no-op. It is issued by the CAU and consumes a location in the CAU FIFO, but has no effect on any CAU register.

### 35.6.3.2 Load Register (LDR)

The LDR command loads CAx with the source data specified by the write data.

### 35.6.3.3 Store Register (STR)

The STR command returns the value of CAx specified in the read address to the destination specified as read data.

### 35.6.3.4 Add to Register (ADR)

The ADR command adds the source operand specified by the write data to CAx and stores the result in CAx.

### 35.6.3.5 Reverse and Add to Register (RADR)

The RADR command performs a byte reverse on the source operand specified by the write data, adds that value to CAx, and stores the result in CAx. The table below shows an example.

**Table 35-16. RADR command example**

| Operand     | CAx before  | CAx after   |
|-------------|-------------|-------------|
| 0x0102_0304 | 0xA0B0_C0D0 | 0xA4B3_C2D1 |

### 35.6.3.6 Add Register to Accumulator (ADRA)

The ADRA command adds CAx to CAA and stores the result in CAA.

### 35.6.3.7 Exclusive Or (XOR)

The XOR command performs an exclusive-or of the source operand specified by the write data with CAx and stores the result in CAx.

### 35.6.3.8 Rotate Left (ROTL)

ROTL rotates the CAx bits to the left with the result stored back to CAx. The number of bits to rotate is the value specified by the write data modulo 32.

### 35.6.3.9 Move Register to Accumulator (MVRA)

The MVRA command moves the value from the source register CAx to the destination register CAA.

### 35.6.3.10 Move Accumulator to Register (MVAR)

The MVAR command moves the value from source register CAA to the destination register CAx.

### 35.6.3.11 AES Substitution (AESS)

The AESS command performs the AES byte substitution operation on CAx and stores the result back to CAx.

### 35.6.3.12 AES Inverse Substitution (AESIS)

The AESIS command performs the AES inverse byte substitution operation on CAx and stores the result back to CAx.

### 35.6.3.13 AES Column Operation (AESC)

The AESC command performs the AES column operation on the contents of CAx. It then performs an exclusive-or of that result with the source operand specified by the write data and stores the result in CAx.

### 35.6.3.14 AES Inverse Column Operation (AESIC)

The AESIC command performs an exclusive-or operation of the source operand specified by the write data on the contents of CAx followed by the AES inverse mix column operation on that result and stores the result back in CAx.

### 35.6.3.15 AES Shift Rows (AESR)

The AESR command performs the AES shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

**Table 35-17. AESR command example**

| Register | Before      | After       |
|----------|-------------|-------------|
| CA0      | 0x0102_0304 | 0x0106_0B00 |
| CA1      | 0x0506_0708 | 0x050A_0F04 |
| CA2      | 0x090A_0B0C | 0x090E_0308 |
| CA3      | 0x0D0E_0F00 | 0x0D02_070C |

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]
- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

### 35.6.3.16 AES Inverse Shift Rows (AESIR)

The AESIR command performs the AES inverse shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

**Table 35-18. AESIR command example**

| Register | Before      | After       |
|----------|-------------|-------------|
| CA0      | 0x0106_0B00 | 0x0102_0304 |
| CA1      | 0x050A_0F04 | 0x0506_0708 |
| CA2      | 0x090E_0308 | 0x090A_0B0C |
| CA3      | 0x0D02_070C | 0x0D0E_0F00 |

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]
- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

### 35.6.3.17 DES Round (DESR)

The DESR command performs a round of the DES algorithm and a key schedule update with the following source and destination designations: CA0=C, CA1=D, CA2=L, CA3=R. If the IP bit is set, DES initial permutation performs on CA2 and CA3 before the round operation. If the FP bit is set, DES final permutation, that is, inverse initial permutation, performs on CA2 and CA3 after the round operation. The round operation

uses the source values from registers CA0 and CA1 for the key addition operation. The KSx field specifies the shift for the key schedule operation to update the values in CA0 and CA1. The following table defines the specific shift function performed based on the KSx field.

**Table 35-19. Key shift function codes**

| KSx code | KSx define | Shift function |
|----------|------------|----------------|
| 0        | KSL1       | Left 1         |
| 1        | KSL2       | Left 2         |
| 2        | KSR1       | Right 1        |
| 3        | KSR2       | Right 2        |

### 35.6.3.18 DES Key setup (DESK)

The DESK command performs the initial key transformation, permuted choice 1, defined by the DES algorithm on CA0 and CA1 with CA0 containing bits 1–32 of the key and CA1 containing bits 33–64 of the key<sup>1</sup>. If the DC bit is set, no shift operation performs and the values C<sub>0</sub> and D<sub>0</sub> store back to CA0 and CA1, respectively. The DC bit must be set for decrypt operations. If the DC bit is not set, a left shift by one also occurs and the values C<sub>1</sub> and D<sub>1</sub> store back to CA0 and CA1, respectively. The DC bit should be cleared for encrypt operations. If the CP bit is set and a key parity error is detected, CASR[DPE] bit is set; otherwise, it is cleared.

### 35.6.3.19 Hash Function (HASH)

The HASH command performs a hashing operation on a set of registers and adds that result to the value in CAA and stores the result in CAA. The specific hash function performed is based on the HFx field as defined in the table below.

This table uses the following terms:

- ROTR<sup>n</sup>(CAx): rotate CAx register right *n* times
- SHR<sup>n</sup>(CAx): shift CAx register right *n* times

**Table 35-20. Hash Function codes**

| HFx code | HFx define | Hash Function | Hash logic                 |
|----------|------------|---------------|----------------------------|
| 0        | HFF        | MD5 F()       | (CA1 & CA2)   (CA1̄ & CA3) |
| 1        | HFG        | MD5 G()       | (CA1 & CA3)   (CA2 & CA3̄) |

*Table continues on the next page...*

1. The DES algorithm numbers the most significant bit of a block as bit 1 and the least significant as bit 64.

**Table 35-20. Hash Function codes (continued)**

| HFx code | HFx define | Hash Function         | Hash logic  |
|----------|------------|-----------------------|---|
| 2        | HFH        | MD5 H(), SHA Parity() | $CA1 \wedge CA2 \wedge CA3$                                 |
| 3        | HFI        | MD5 I()               | $CA2 \wedge (CA1 \mid CA3)$                                 |
| 4        | HFC        | SHA Ch()              | $(CA1 \& CA2) \wedge (\overline{CA1} \& CA3)$               |
| 5        | HFM        | SHA Maj()             | $(CA1 \& CA2) \wedge (CA1 \& CA3) \wedge (CA2 \& CA3)$      |
| 6        | HF2C       | SHA-256 Ch()          | $(CA4 \& CA5) \wedge (\overline{CA1} \& CA6)$               |
| 7        | HF2M       | SHA-256 Maj()         | $(CA0 \& CA1) \wedge (CA0 \& CA2) \wedge (CA1 \& CA2)$      |
| 8        | HF2S       | SHA-256 Sigma 0       | $ROTR^2(CA0) \wedge ROTR^{13}(CA0) \wedge ROTR^{22}(CA0)$   |
| 9        | HF2T       | SHA-256 Sigma 1       | $ROTR^6(CA4) \wedge ROTR^{11}(CA4) \wedge ROTR^{25}(CA4)$   |
| A        | HF2U       | SHA-256 Sigma 0       | $ROTR^7(CA8) \wedge ROTR^{18}(CA8) \wedge SHR^3(CA8)$       |
| B        | HF2V       | SHA-256 Sigma 1       | $ROTR^{17}(CA8) \wedge ROTR^{19}(CA8) \wedge SHR^{10}(CA8)$ |

### 35.6.3.20 Secure Hash Shift (SHS)

The SHS command does a set of parallel register-to-register move and shift operations for implementing SHA-1. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA4      | CA4                    | CA3                          |
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | $CA1 \lll 30$                |
| CA1      | CA1                    | CA0                          |
| CA0      | CA0                    | CAA                          |
| CAA      | CAA                    | $CAA \lll 5$                 |

### 35.6.3.21 Message Digest Shift (MDS)

The MDS command does a set of parallel register-to-register move operations for implementing MD5. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | CA1                          |

### 35.6.3.22 Secure Hash Shift 2 (SHS2)

The SHS2 command does an addition and a set of register to register moves in parallel for implementing SHA-256. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA7      | CA7                    | CA6                          |
| CA6      | CA6                    | CA5                          |
| CA5      | CA5                    | CA4                          |
| CA4      | CA4                    | CA3+CA8                      |
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | CA1                          |
| CA1      | CA1                    | CA0                          |
| CA0      | CA0                    | CAA                          |

### 35.6.3.23 Illegal command (ILL)

The ILL command is a specific illegal command that sets CASR[IC]. All other illegal commands are reserved for use in future implementations.

## 35.7 Application/initialization information

This section discusses how to initialize and use the CAU.

### 35.7.1 Code example

A code fragment is shown below as an example of how the CAU is used. This example shows the round function of the AES algorithm. Core registers are defined as follows:

- R1 points to the key schedule
- R3 contains 3 direct CAU commands
- R8 contains 2 direct CAU commands
- R9 contains an indirect CAU command
- FP points to the CAU indirect command address space
- IP points to the CAU direct command space

```

movw    fp, #:lower16:MMCAU_PPB_INDIRECT      @ fp -> MMCAU_PPB_INDIRECT
movt    fp, #:upper16:MMCAU_PPB_INDIRECT
movw    ip, #:lower16:MMCAU_PPB_DIRECT        @ ip -> MMCAU_PPB_DIRECT
movt    ip, #:upper16:MMCAU_PPB_DIRECT
    
```

## Application/initialization information

```
# r3 = mmcau_3_cmds (AESS+CA0,AESS+CA1,AESS+CA2)
    movw    r3, #:lower16:(0x80100200+(AESS+CA0)<<22+(AESS+CA1)<<11+AESS+CA2)
    movt    r3, #:upper16:(0x80100200+(AESS+CA0)<<22+(AESS+CA1)<<11+AESS+CA2)

# r8 = mmcau_2_cmds (AESS+CA3,AESR)
    movw    r8, #:lower16:(0x80100000+(AESS+CA3)<<22+(AESR)<<11)
    movt    r8, #:upper16:(0x80100000+(AESS+CA3)<<22+(AESR)<<11)

    add     r9, fp, $(AESC+CA0)<<2)                @ r9 = mmcau_cmd(AESC+CA0)

    str     r3, [ip]                                @ sub bytes w0, w1, w2
    str     r8, [ip]                                @ sub bytes w3, shift rows
    ldmia   r1!, {r4-r7}                            @ get next 4 keys; r1++
    stmia   r9, {r4-r7}                             @ mix columns, add keys
```

## 35.7.2 Assembler equate values

The following equates ease programming of the CAU.

```
; CAU Registers (CAx)
    .set CASR,0x0
    .set CAA,0x1
    .set CA0,0x2
    .set CA1,0x3
    .set CA2,0x4
    .set CA3,0x5
    .set CA4,0x6
    .set CA5,0x7
    .set CA6,0x8
    .set CA7,0x9
    .set CA8,0xA

; CAU Commands
    .set CNOP,0x000
    .set LDR,0x010

.set HF2V,0xB         ; SHA-256 sigma 1 ROTR17(CA8)^ROTR19(CA8)^SHR10(CA8)

```

## Chapter 36

# Random Number Generator Accelerator (RNGA)

### 36.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes the random-number-generator accelerator RNGA, including a programming model, functional description, and application information. Throughout this chapter, the terms "RNG" and "RNGA" are meant to be synonymous.

#### 36.1.1 Overview

RNGA is a digital integrated circuit capable of generating 32-bit random numbers. The random bits are generated using shift registers with clocks derived from two free-running, independent ring oscillators. The configuration of the shift registers ensures statistically good data, that is, data that looks random. The oscillators, with their unknown frequencies and independent phases, provide the means of generating the required entropy needed to create random data. The random words generated by RNGA are loaded into an output register (OR). RNGA is designed to generate an error interrupt (if not masked), if OR is read and does not contain valid random data. OR contains valid random data if the LVL field in the status register (SR) is 1.

It is important to note there is no known cryptographic proof showing this is a secure method of generating random data. In fact, there may be an attack against this random number generator if its output is used directly in a cryptographic application. The attack is based on the linearity of the internal shift registers. Therefore, it is highly recommended that this random data produced by this module be used as an entropy source to provide an input seed to a NIST-approved pseudo-random-number generator based on DES or SHA-1 and defined in *NIST FIPS PUB 186-2 Appendix 3* and *NIST FIPS PUB SP 800-90*.

The requirement is to maximize the entropy of this input seed. In order to do this, when data is extracted from RNGA as quickly as the hardware allows, there are about one or two bits of added entropy per 32-bit word. Any single bit of that word contains that entropy. Therefore, when used as an entropy source, a random number should be generated for each bit of entropy required, and the least significant bit (any bit would be equivalent) of each word retained. The remainder of each random number should then be discarded. Used this way, even with full knowledge of the internal state of RNGA and all prior random numbers, an attacker is not able to predict the values of the extracted bits.

Other sources of entropy can be used along with RNGA to generate the seed to the pseudorandom algorithm. The more random sources combined to create the seed, the better. The following is a list of sources that can be easily combined with the output of this module:

- Current time using highest precision possible
- Real-time system inputs that can be characterized as "random"
- Other entropy supplied directly by the user

## 36.2 Modes of operation

RNGA supports the following modes of operation.

**Table 36-1. Modes of operation supported by RNGA**

| Mode   | Description  |
|--------|--|
| Normal | The ring-oscillator clocks are active; RNGA generates entropy (randomness) from the clocks and stores it in shift registers. |
| Sleep  | The ring-oscillator clocks are inactive; RNGA does not generate entropy.   |

### 36.2.1 Entering Normal mode

To enter Normal mode, write 0 to CR[SLP].

## 36.2.2 Entering Sleep mode

To enter Sleep mode, write 1 to CR[SLP].

## 36.3 Memory map and register definition

This section describes the RNGA registers.

RNG memory map

| Absolute address (hex) | Register name                  | Width (in bits) | Access                | Reset value | Section/page               |
|------------------------|--------------------------------|-----------------|-----------------------|-------------|----------------------------|
| 400A_0000              | RNGA Control Register (RNG_CR) | 32              | R/W                   | 0000_0000h  | <a href="#">36.3.1/953</a> |
| 400A_0004              | RNGA Status Register (RNG_SR)  | 32              | R                     | 0001_0000h  | <a href="#">36.3.2/955</a> |
| 400A_0008              | RNGA Entropy Register (RNG_ER) | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">36.3.3/957</a> |
| 400A_000C              | RNGA Output Register (RNG_OR)  | 32              | R                     | 0000_0000h  | <a href="#">36.3.4/957</a> |

### 36.3.1 RNGA Control Register (RNG\_CR)

Controls the operation of RNGA.

Address: 400A\_0000h base + 0h offset = 400A\_0000h

|       |          |    |    |    |    |    |    |    |    |    |    |      |          |          |          |          |
|-------|----------|----|----|----|----|----|----|----|----|----|----|------|----------|----------|----------|----------|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20   | 19       | 18       | 17       | 16       |
| R     | 0        |    |    |    |    |    |    |    |    |    |    |      |          |          |          |          |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |      |          |          |          |          |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0    | 0        | 0        | 0        | 0        |
| Bit   | 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4    | 3        | 2        | 1        | 0        |
| R     | 0        |    |    |    |    |    |    |    |    |    |    | SLP  | 0        | INTM     | HA       | GO       |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    | CLRI | [Shaded] | [Shaded] | [Shaded] | [Shaded] |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0    | 0        | 0        | 0        | 0        |

### RNG\_CR field descriptions

| Field            | Description  |
|------------------|--|
| 31–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4<br>SLP         | Sleep<br>Specifies whether RNGA is in Sleep or Normal mode.<br><b>NOTE:</b> You can also enter Sleep mode by asserting the DOZE signal.<br><br>0 Normal mode<br>1 Sleep (low-power) mode   |
| 3<br>CLRI        | Clear Interrupt<br>Clears the interrupt by resetting the error-interrupt indicator (SR[ERRI]).<br><br>0 Do not clear the interrupt.<br>1 Clear the interrupt. When you write 1 to this field, RNGA then resets the error-interrupt indicator (SR[ERRI]). This bit always reads as 0.   |
| 2<br>INTM        | Interrupt Mask<br>Masks the triggering of an error interrupt to the interrupt controller when an OR underflow condition occurs.<br>An OR underflow condition occurs when you read OR[RANDOUT] and SR[OREG_LVL]=0. See the Output Register (OR) description.<br><br>0 Not masked<br>1 Masked                                    |
| 1<br>HA          | High Assurance<br>Enables notification of security violations (via SR[SECV]).<br>A security violation occurs when you read OR[RANDOUT] and SR[OREG_LVL]=0.<br><b>NOTE:</b> This field is sticky. After enabling notification of security violations, you must reset RNGA to disable them again.<br><br>0 Disabled<br>1 Enabled |
| 0<br>GO          | Go<br>Specifies whether random-data generation and loading (into OR[RANDOUT]) is enabled.<br><b>NOTE:</b> This field is sticky. You must reset RNGA to stop RNGA from loading OR[RANDOUT] with data.<br><br>0 Disabled<br>1 Enabled  |

### 36.3.2 RNGA Status Register (RNG\_SR)

Indicates the status of RNGA. This register is read-only.

Address: 400A\_0000h base + 4h offset = 400A\_0004h

|       |            |    |    |    |    |    |    |    |           |    |     |      |     |     |      |    |
|-------|------------|----|----|----|----|----|----|----|-----------|----|-----|------|-----|-----|------|----|
| Bit   | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21  | 20   | 19  | 18  | 17   | 16 |
| R     | 0          |    |    |    |    |    |    |    | OREG_SIZE |    |     |      |     |     |      |    |
| W     | [Reserved] |    |    |    |    |    |    |    |           |    |     |      |     |     |      |    |
| Reset | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  | 0   | 0    | 0   | 0   | 0    | 1  |
| Bit   | 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5   | 4    | 3   | 2   | 1    | 0  |
| R     | OREG_LVL   |    |    |    |    |    |    |    | 0         |    | SLP | ERRI | ORU | LRS | SECV |    |
| W     | [Reserved] |    |    |    |    |    |    |    |           |    |     |      |     |     |      |    |
| Reset | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  | 0   | 0    | 0   | 0   | 0    | 0  |

**RNG\_SR field descriptions**

| Field              | Description   |
|--------------------|---|
| 31–24<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 23–16<br>OREG_SIZE | Output Register Size<br>Indicates the size of the Output (OR) register in terms of the number of 32-bit random-data words it can hold.<br><br>1 One word (this value is fixed)  |
| 15–8<br>OREG_LVL   | Output Register Level<br>Indicates the number of random-data words that are in OR[RANDOUT], which indicates whether OR[RANDOUT] is valid.<br><br><b>NOTE:</b> If you read OR[RANDOUT] when SR[OREG_LVL] is not 0, then the contents of a random number contained in OR[RANDOUT] are returned, and RNGA writes 0 to both OR[RANDOUT] and SR[OREG_LVL].<br><br>0 No words (empty)<br>1 One word (valid) |

Table continues on the next page...

### RNG\_SR field descriptions (continued)

| Field           | Description  |
|-----------------|--|
| 7–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4<br>SLP        | Sleep<br>Specifies whether RNGA is in Sleep or Normal mode.<br><b>NOTE:</b> You can also enter Sleep mode by asserting the DOZE signal.<br>0 Normal mode<br>1 Sleep (low-power) mode   |
| 3<br>ERRI       | Error Interrupt<br>Indicates whether an OR underflow condition has occurred since you last cleared the error interrupt (CR[CLRI]) or RNGA was reset, regardless of whether the error interrupt is masked (CR[INTM]).<br>An OR underflow condition occurs when you read OR[RANDOUT] and SR[OREG_LVL]=0.<br><b>NOTE:</b> After you reset the error-interrupt indicator (via CR[CLRI]), RNGA writes 0 to this field.<br>0 No underflow<br>1 Underflow |
| 2<br>ORU        | Output Register Underflow<br>Indicates whether an OR underflow condition has occurred since you last read this register (SR) or RNGA was reset, regardless of whether the error interrupt is masked (CR[INTM]).<br>An OR underflow condition occurs when you read OR[RANDOUT] and SR[OREG_LVL]=0.<br><b>NOTE:</b> After you read this register, RNGA writes 0 to this field.<br>0 No underflow<br>1 Underflow                                      |
| 1<br>LRS        | Last Read Status<br>Indicates whether the most recent read of OR[RANDOUT] caused an OR underflow condition, regardless of whether the error interrupt is masked (CR[INTM]).<br>An OR underflow condition occurs when you read OR[RANDOUT] and SR[OREG_LVL]=0.<br><b>NOTE:</b> After you read this register, RNGA writes 0 to this field.<br>0 No underflow<br>1 Underflow  |
| 0<br>SECV       | Security Violation<br>Used only when high assurance is enabled (CR[HA]). Indicates that a security violation has occurred.<br><b>NOTE:</b> This field is sticky. To clear SR[SECV], you must reset RNGA.<br>0 No security violation<br>1 Security violation  |

### 36.3.3 RNGA Entropy Register (RNG\_ER)

Specifies an entropy value that RNGA uses in addition to its ring oscillators to seed its pseudorandom algorithm. This is a write-only register; reads return all zeros.

Address: 400A\_0000h base + 8h offset = 400A\_0008h

#### RNG\_ER field descriptions

| Field           | Description   |
|-----------------|---|
| 31–0<br>EXT_ENT | <p>External Entropy</p> <p>Specifies an entropy value that RNGA uses in addition to its ring oscillators to seed its pseudorandom algorithm.</p> <p><b>NOTE:</b> Specifying a value for this field is optional but recommended. You can write to this field at any time during operation.</p> |

### 36.3.4 RNGA Output Register (RNG\_OR)

Stores a random-data word generated by RNGA.

Address: 400A\_0000h base + Ch offset = 400A\_000Ch

#### RNG\_OR field descriptions

| Field           | Description   |
|-----------------|---|
| 31–0<br>RANDOUT | <p>Random Output</p> <p>Stores a random-data word generated by RNGA. This is a read-only field.</p> <p><b>NOTE:</b> Before reading RANDOUT, be sure it is valid (SR[OREG_LVL]=1).</p> |

### RNG\_OR field descriptions (continued)

| Field            | Description  |
|------------------|--|
| 0                | Invalid data (if you read this field when it is 0 and SR[OREG_LVL] is 0, RNGA then writes 1 to SR[ERRI], SR[ORU], and SR[LRS]; when the error interrupt is not masked (CR[INTM]=0), RNGA also asserts an error interrupt request to the interrupt controller). |
| All other values | Valid data (if you read this field when SR[OREG_LVL] is not 0, RNGA returns RANDOUT, and then writes 0 to this field and to SR[OREG_LVL]).   |

## 36.4 Functional description

This is a block diagram of RNGA.

Figure 36-5. RNGA block diagram

### 36.4.1 Output (OR) register

The Output (OR) register provides temporary storage for random data generated by the core engine / control logic. The Status (SR) register allows the user to monitor the presence of valid random data in OR through SR[OREG\_LVL].

If the OR is read while containing valid random data (as signaled by SR[OREG\_LVL] = 1), the valid data is returned, then OR and SR[OREG\_LVL] are both cleared. If the user reads from OR when it is empty, RNGA returns all zeros and, if the interrupt is enabled, RNGA drives a request to the interrupt controller. Polling SR[OREG\_LVL] is very important to make sure random values are present before reading from OR.

## 36.4.2 Core engine / control logic

This block contains RNGA's control logic as well as its core engine used to generate random data.

### 36.4.2.1 Control logic

The control logic contains the address decoder, all addressable registers, and control state machines for RNGA. This block is responsible for communication with both the peripheral interface and the Output (OR) register interface. The block also controls the core engine to generate random data. The general functionality of the block is as follows:

After reset, RNGA operates in Normal mode as follows:

1. The core engine generates entropy and stores it in the shift registers.
2. After you enable random-data generation by loading CR[GO], every 256 clock cycles the core engine generates a new random-data word. If SR[OREG\_LVL] = 0, then the control block loads the new random data into OR and set SR[OREG\_LVL] = 1; else the new data is discarded.

### 36.4.2.2 Core engine

The core engine block contains the logic used to generate random data. The logic within the core engine contains the internal shift registers as well as the logic used to generate the two oscillator-based clocks. The control logic determines how the shift registers are configured as well as when the oscillator clocks are turned on.

## 36.5 Initialization/application information

The intended general operation of RNGA is as follows:

1. Reset/initialize.
2. Write 1 to CR[INTM], CR[HA], and CR[GO].
3. Poll SR[OREG\_LVL] until it is not 0.
4. When SR[OREG\_LVL] is not 0, read the available random data from OR[RANDOUT].
5. Repeat steps 3 and 4 as needed.

For application information, see [Overview](#).

# Chapter 37

## Analog-to-Digital Converter (ADC)

### 37.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The 16-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

#### NOTE

For the chip specific modes of operation, see the power management information of the device.

#### 37.1.1 Features

Following are the features of the ADC module.

- Linear successive approximation algorithm with up to 16-bit resolution
- Up to four pairs of differential and 24 single-ended external analog inputs
- Output modes:
  - differential 16-bit, 13-bit, 11-bit, and 9-bit modes
  - single-ended 16-bit, 12-bit, 10-bit, and 8-bit modes
- Output format in 2's complement 16-bit sign extended for differential modes
- Output in right-justified unsigned format for single-ended
- Single or continuous conversion, that is, automatic return to idle after single conversion

- Configurable sample time and conversion speed/power
- Conversion complete/hardware average complete flag and interrupt
- Input clock selectable from up to four sources
- Operation in low-power modes for lower noise
- Asynchronous clock source for lower noise operation with option to output the clock
- Selectable hardware conversion trigger with hardware channel select
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Temperature sensor
- Hardware average function
- Selectable voltage reference: external or alternate
- Self-Calibration mode
- Programmable Gain Amplifier (PGA) with up to x64 gain

### 37.1.2 Block diagram

The following figure is the ADC module block diagram.

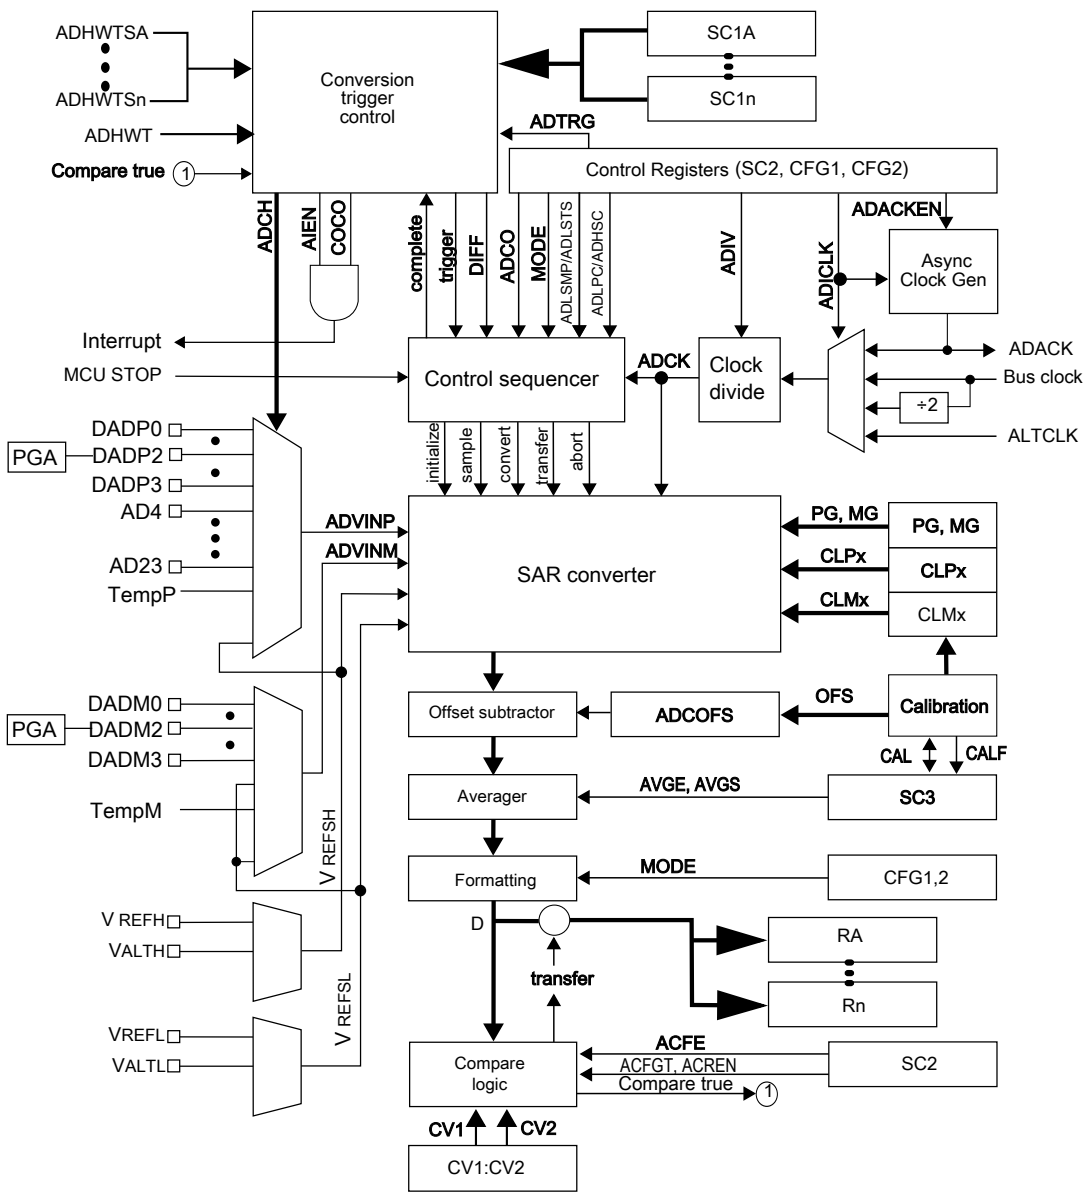

Figure 37-1. ADC block diagram

### 37.2 ADC signal descriptions

The ADC module supports up to 4 pairs of differential inputs and up to 24 single-ended inputs.

Each differential pair requires two inputs, DADPx and DADMx. The ADC also requires four supply/reference/ground connections.

## NOTE

For the number of channels supported on this device as well as information regarding other chip-specific inputs into the ADC block, see the chip-specific ADC configuration information.

**Table 37-1. ADC signal descriptions**

| Signal             | Description                        | I/O |
|--------------------|------------------------------------|-----|
| DADP3–DADP0        | Differential Analog Channel Inputs | I   |
| DADM3–DADM0        | Differential Analog Channel Inputs | I   |
| AD $n$             | Single-Ended Analog Channel Inputs | I   |
| V <sub>REFSH</sub> | Voltage Reference Select High      | I   |
| V <sub>REFSL</sub> | Voltage Reference Select Low       | I   |
| V <sub>DDA</sub>   | Analog Power Supply                | I   |
| V <sub>SSA</sub>   | Analog Ground                      | I   |

### 37.2.1 Analog Power (V<sub>DDA</sub>)

The ADC analog portion uses V<sub>DDA</sub> as its power connection. In some packages, V<sub>DDA</sub> is connected internally to V<sub>DD</sub>. If externally available, connect the V<sub>DDA</sub> pin to the same voltage potential as V<sub>DD</sub>. External filtering may be necessary to ensure clean V<sub>DDA</sub> for good results.

### 37.2.2 Analog Ground (V<sub>SSA</sub>)

The ADC analog portion uses V<sub>SSA</sub> as its ground connection. In some packages, V<sub>SSA</sub> is connected internally to V<sub>SS</sub>. If externally available, connect the V<sub>SSA</sub> pin to the same voltage potential as V<sub>SS</sub>.

### 37.2.3 Voltage Reference Select

V<sub>REFSH</sub> and V<sub>REFSL</sub> are the high and low reference voltages for the ADC module.

The ADC can be configured to accept one of two voltage reference pairs for V<sub>REFSH</sub> and V<sub>REFSL</sub>. Each pair contains a positive reference that must be between the minimum Ref Voltage High and V<sub>DDA</sub>, and a ground reference that must be at the same potential as V<sub>SSA</sub>. The two pairs are external (V<sub>REFH</sub> and V<sub>REFL</sub>) and alternate (V<sub>ALTH</sub> and V<sub>ALTL</sub>). These voltage references are selected using SC2[REFSEL]. The alternate V<sub>ALTH</sub> and

$V_{ALTL}$  voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the Voltage References specific to this MCU.

In some packages,  $V_{REFH}$  is connected in the package to  $V_{DDA}$  and  $V_{REFL}$  to  $V_{SSA}$ . If externally available, the positive reference(s) may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source to a level between the minimum Ref Voltage High and the  $V_{DDA}$  potential.  $V_{REFH}$  must never exceed  $V_{DDA}$ . Connect the ground references to the same voltage potential as  $V_{SSA}$ .

### 37.2.4 Analog Channel Inputs (ADx)

The ADC module supports up to 24 single-ended analog inputs. A single-ended input is selected for conversion through the  $SC1[ADCH]$  channel select bits when  $SC1n[DIFF]$  is low.

### 37.2.5 Differential Analog Channel Inputs (DADx)

The ADC module supports up to four differential analog channel inputs. Each differential analog input is a pair of external pins,  $DADPx$  and  $DADMx$ , referenced to each other to provide the most accurate analog to digital readings. A differential input is selected for conversion through  $SC1[ADCH]$  when  $SC1n[DIFF]$  is high. All  $DADPx$  inputs may be used as single-ended inputs if  $SC1n[DIFF]$  is low. In certain MCU configurations, some  $DADMx$  inputs may also be used as single-ended inputs if  $SC1n[DIFF]$  is low. For ADC connections specific to this device, see the chip-specific ADC information.

## 37.3 Memory map and register definitions

This section describes the ADC registers.

**ADC memory map**

| Absolute address (hex) | Register name                                  | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|--|-----------------|--------|-------------|----------------------------|
