### 37.3.1 ADC Status and Control Registers 1 (ADCx\_SC1n)

SC1A is used for both software and hardware trigger modes of operation.

To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC can have more than one status and control register: one for each conversion. The SC1B–SC1n registers indicate potentially multiple SC1 registers for use only in hardware trigger mode. See the chip configuration information about the number of SC1n registers specific to this device. The SC1n registers have identical fields, and are used in a "ping-pong" approach to control ADC operation.

At any one point in time, only one of the SC1n registers is actively controlling ADC conversions. Updating SC1A while SC1n is actively controlling a conversion is allowed, and vice-versa for any of the SC1n registers specific to this MCU.

Writing SC1A while SC1A is actively controlling a conversion aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, writes to SC1A subsequently initiate a new conversion, if SC1[ADCH] contains a value other than all 1s (module disabled).

Writing any of the SC1n registers while that specific SC1n register is actively controlling a conversion aborts the current conversion. None of the SC1B–SC1n registers are used for software trigger operation and therefore writes to the SC1B–SC1n registers do not initiate a new conversion.

Address: Base address + 0h offset + (4d × i), where i=0d to 1d

ADCx\_SC1n field descriptions

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7<br>COCO        | Conversion Complete Flag<br><br>This is a read-only field that is set each time a conversion is completed when the compare function is disabled, or SC2[ACFE]=0 and the hardware average function is disabled, or SC3[AVGE]=0. When the compare function is enabled, or SC2[ACFE]=1, COCO is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled, or SC3[AVGE]=1, COCO is set upon completion of the selected number of conversions (determined by AVGS). COCO in SC1A is also set at the completion of a calibration sequence. COCO is cleared when the respective SC1n register is written or when the respective Rn register is read.<br><br>0 Conversion is not completed.<br>1 Conversion is completed. |
| 6<br>AIEN        | Interrupt Enable<br><br>Enables conversion complete interrupts. When COCO becomes set while the respective AIEN is high, an interrupt is asserted.<br><br>0 Conversion complete interrupt is disabled.<br>1 Conversion complete interrupt is enabled.  |
| 5<br>DIFF        | Differential Mode Enable<br><br>Configures the ADC to operate in differential mode. When enabled, this mode automatically selects from the differential channels, and changes the conversion algorithm and the number of cycles to complete a conversion.<br><br>0 Single-ended conversions and input channels are selected.<br>1 Differential conversions and input channels are selected.  |

DAD0-DAD3 are associated with the input pin pairs DADPx and DADMx.<br><br><b>NOTE:</b> Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the actual ADC channel assignments for your device, see the Chip Configuration details.  |

Table continues on the next page...

### ADCx\_SC1n field descriptions (continued)

| Field | Description  |
|-------|--|
|       | The successive approximation converter subsystem is turned off when the channel select bits are all set, that is, ADCH = 11111. This feature allows explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional single conversion from being performed. It is not necessary to set ADCH to all 1s to place the ADC in a low-power state when continuous conversions are not enabled because the module automatically enters a low-power state when a conversion completes. |
| 00000 | When DIFF=0, DADP0 is selected as input; when DIFF=1, DAD0 is selected as input.   |
| 00001 | When DIFF=0, DADP1 is selected as input; when DIFF=1, DAD1 is selected as input.   |

#### 37.3.4 ADC Data Result Register (ADCx\_Rn)

The data result registers (Rn) contain the result of an ADC conversion of the channel selected by the corresponding status and channel control register (SC1A:SC1n). For every status and channel control register, there is a corresponding data result register.

Unused bits in R<sub>n</sub> are cleared in unsigned right-aligned modes and carry the sign bit (MSB) in sign-extended 2's complement modes. For example, when configured for 10-bit single-ended mode, D[15:10] are cleared. When configured for 11-bit differential mode, D[15:10] carry the sign bit, that is, bit 10 extended through bit 15.

The following table describes the behavior of the data result registers in the different modes of operation.

**Table 37-44. Data result register description**

| Conversion mode     | D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | Format                       |
|---------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|------------------------------|

**NOTE**

S: Sign bit or sign bit extension;

D: Data, which is 2's complement data if indicated

Address: Base address + 10h offset + (4d × i), where i=0d to 1d

**ADCx\_Rn field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>D         | Data result   |

### 37.3.5 Compare Value Registers (ADCx\_CVn)

The Compare Value Registers (CV1 and CV2) contain a compare value used to compare the conversion result when the compare function is enabled, that is, SC2[ACFE]=1. This register is formatted in the same way as the Rn registers in different modes of operation for both bit position definition and value format using unsigned or sign-extended 2's complement. Therefore, the compare function uses only the CVn fields that are related to the ADC mode of operation.

The compare value 2 register (CV2) is used only when the compare range function is enabled, that is, SC2[ACREN]=1.

Address: Base address + 18h offset + (4d × i), where i=0d to 1d

#### ADCx\_CVn field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>CV        | Compare Value.  |

### 37.3.6 Status and Control Register 2 (ADCx\_SC2)

The status and control register 2 (SC2) contains the conversion active, hardware/software trigger select, compare function, and voltage reference select of the ADC module.

Address: Base address + 20h offset

**37.3.8 ADC Offset Correction Register (ADCx\_OFS)**

The ADC Offset Correction Register (OFS) contains the user-selected or calibration-generated offset error correction value. This register is a 2’s complement, left-justified, 16-bit value . The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

Address: Base address + 28h offset

**ADCx\_OFS field descriptions**

| Field             | Description  |
|-------------------|--|
| 31–16<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p> |

| Field       | Description                   |
|-------------|-------------------------------|
| 15–0<br>OFS | Offset Error Correction Value |

**37.3.9 ADC Plus-Side Gain Register (ADCx\_PG)**

The Plus-Side Gain Register (PG) contains the gain error correction for the plus-side input in differential mode or the overall conversion in single-ended mode. PG, a 16-bit real number in binary format, is the gain adjustment factor, with the radix point fixed between PG[15] and PG[14]. This register must be written by the user with the value described in the calibration procedure. Otherwise, the gain error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

Address: Base address + 2Ch offset

**ADCx\_PG field descriptions**

|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>PG        | Plus-Side Gain  |

**37.3.10 ADC Minus-Side Gain Register (ADCx\_MG)**

The Minus-Side Gain Register (MG) contains the gain error correction for the minus-side input in differential mode. This register is ignored in single-ended mode. MG, a 16-bit real number in binary format, is the gain adjustment factor, with the radix point fixed between MG[15] and MG[14]. This register must be written by the user with the value described in the calibration procedure. Otherwise, the gain error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

Address: Base address + 30h offset

**37.3.11 ADC Plus-Side General Calibration Value Register (ADCx\_CLPD)**

The Plus-Side General Calibration Value Registers (CLPx) contain calibration information that is generated by the calibration function. These registers contain seven calibration values of varying widths: CLP0[5:0], CLP1[6:0], CLP2[7:0], CLP3[8:0], CLP4[9:0], CLPS[5:0], and CLPD[5:0]. CLPx are automatically set when the self-calibration sequence is done, that is, CAL is cleared. If these registers are written by the user after calibration, the linearity error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

## 37.4 Functional description

The ADC module is disabled during reset, in Low-Power Stop mode, or when SC1n[ADCH] are all high; see the power management information for details. The module is idle when a conversion has completed and another conversion has not been initiated. When it is idle and the asynchronous clock output enable is disabled, or CFG2[ADACKEN]= 0, the module is in its lowest power state. The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications, the ADC module must be calibrated using the on-chip calibration function.

See [Calibration function](#) for details on how to perform calibration.

When the conversion is completed, the result is placed in the Rn data registers. The respective SC1n[COCO] is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, or, when SC1n[AIEN]=1.

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the CV1 and CV2 registers. The compare function is enabled by setting SC2[ACFE] and operates in any of the conversion modes and configurations.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting SC3[AVGE] and operates in any of the conversion modes and configurations.

### NOTE

For the chip specific modes of operation, see the power management information of this MCU.

### 37.4.1 PGA functional description

The Programmable Gain Amplifier (PGA) is designed to increase the dynamic range by amplifying low-amplitude signals before they are fed to the 16-bit Successive Approximation Register (SAR) ADC. The gain of this amplifier ranges between 1 to 64 in ( $2^N$ ) steps, that is, 1, 2, 4, 8, 16, 32, and 64.

This block is designed to work with differential input and output with input signals that range from 0 to 1.2 V  $\pm$  10 mV. The output common mode of the PGA is determined based on the SAR ADC requirement.

The PGA has only one voltage reference pair. The positive reference used is chip-specific and depends on the MCU configuration. The ground reference is the analog ground for the PGA. See the chip configuration chapter on the PGA voltage reference specific to this MCU.

The PGA register allows to control the PGA gain and modes of operation.

The PGA employs chopping to remove/reduce offset and 1/f noise and offers an offset measurement configuration that aids offset calibration. These two are user programmable features and the details are given below.

### **PGA Chopping:**

The PGA chopping is controlled by PGACHPb bit in PGA register. The default value is 0 (enabled). User can disable the chopping by writing 1 to this register bit. Due to the operation of the PGA chopping, to achieve the specified PGA accuracy, the user must operate the ADC with hardware averaging enabled or must average an even number of samples in software. These samples must be gathered by the ADC with no ADC conversion on a different channel or at a different ADC configuration between the samples. A time delta between the samples controlled by software or hardware trigger (PDB) is allowed. If the PGA is used without averaging or if single conversion is required, chopping should be disabled. While chopping removes the maximum offset and 1/f noise, it mandates averaging to be done. For cases requiring higher effective sampling rate (therefore no averaging) but lower accuracy, the chopping may be disabled and offset calibration may be employed instead. In PGA mode, it is recommended to run the ADC with maximum possible sample rate to get maximum benefit of chopping.

### **Measurement of PGA offset and offset calibration in software:**

The offset of the PGA can be measured by setting PGAOFSM bit in PGA register. When this bit is set, the PGA disconnects itself from the external inputs and auto-configures into offset measurement mode at x64 gain. With this bit set, run the ADC in recommended settings and enable maximum hardware averaging to get the PGA offset number. The output will be (PGA offset \* (64+1)) for the given PGA setting. If chopping is enabled during offset measurement, this measures the residual PGA offset after chopping. If chopping is disabled during offset measurement, this measures the non-chopped PGA offset. PGA offset can be calibrated in software with the help of the above measured value. Store the measured offset (X) in memory for the desired setting. Subtract  $[(X/(64+1))*(G+1)]$  from the result, where G is the PGA gain during operation.

### **Digital LPF to improve SNR/ENOB:**

For low-frequency and high-accuracy applications, on top of averaging, user may digitally filter the ADC output to cut out-of-band noise to get improvement in SNR/ENOB from what is specified in device data sheet.

## 37.4.2 Clock select and divide control

One of four clock sources can be selected as the clock source for the ADC module.

This clock source is then divided by a configurable value to generate the input clock ADCK, to the module. The clock is selected from one of the following sources by means of CFG1[ADICLK].

- Bus clock. This is the default selection following reset.
- Bus clock divided by two. For higher bus clock rates, this allows a maximum divide-by-16 of the bus clock using CFG1[ADIV].
- ALTCLK: As defined for this MCU. See the chip configuration information. Conversions are possible using ALTCLK as the input clock source while the MCU is in Normal Stop mode.
- Asynchronous clock (ADACK): This clock is generated from a clock source within the ADC module. When the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start CFG2[ADACKEN]=0, ADACK is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated. To avoid the conversion time variability and latency associated with the ADACK clock startup, set CFG2[ADACKEN]=1 and wait the worst-case startup time of 5  $\mu$ s prior to initiating any conversions using the ADACK clock source. Conversions are possible using ADACK as the input clock source while the MCU is in Normal Stop mode. See [Power Control](#) for more information.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by CFG1[ADIV] and can be divide-by 1, 2, 4, or 8.

## 37.4.3 Voltage reference selection

The ADC can be configured to accept one of the two voltage reference pairs as the reference voltage ( $V_{REFSH}$  and  $V_{REFSL}$ ) used for conversions.

Each pair contains a positive reference that must be between the minimum Ref Voltage High and  $V_{DDA}$ , and a ground reference that must be at the same potential as  $V_{SSA}$ . The two pairs are external ( $V_{REFH}$  and  $V_{REFL}$ ) and alternate ( $V_{ALTH}$  and  $V_{ALTTL}$ ). These voltage references are selected using  $SC2[REFSEL]$ . The alternate ( $V_{ALTH}$  and  $V_{ALTTL}$ ) voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

### 37.4.4 Hardware trigger and channel selects

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when  $SC2[ADTRG]$  is set and a hardware trigger select event, ADHWTSn, has occurred.

This source is not available on all MCUs. See the chip-specific ADC information for information on the ADHWT source and the ADHWTSn configurations specific to this MCU.

When an ADHWT source is available and hardware trigger is enabled, that is  $SC2[ADTRG]=1$ , a conversion is initiated on the rising-edge of ADHWT after a hardware trigger select event, that is, ADHWTSn, has occurred. If a conversion is in progress when a rising-edge of a trigger occurs, the rising-edge is ignored. In continuous convert configuration, only the initial rising-edge to launch continuous conversions is observed, and until conversion is aborted, the ADC continues to do conversions on the same SCn register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The hardware trigger select event, ADHWTSn, must be set prior to the receipt of the ADHWT signal. If these conditions are not met, the converter may ignore the trigger or use the incorrect configuration. If a hardware trigger select event is asserted during a conversion, it must stay asserted until the end of current conversion and remain set until the receipt of the ADHWT signal to trigger a new conversion. The channel and status fields selected for the conversion depend on the active trigger select signal:

- ADHWTS<sub>A</sub> active selects SC<sub>1A</sub>.
- ADHWTS<sub>n</sub> active selects SC<sub>1n</sub>.

#### Note

Asserting more than one hardware trigger select signal (ADHWTS<sub>n</sub>) at the same time results in unknown results. To avoid this, select only one hardware trigger select signal (ADHWTS<sub>n</sub>) prior to the next intended conversion.

When the conversion is completed, the result is placed in the Rn registers associated with the ADHWTSn received. For example:

- ADHWTSa active selects RA register
- ADHWTSn active selects Rn register

The conversion complete flag associated with the ADHWTSn received, that is, SC1n[COCO], is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, that is, SC1[AIEN]=1.

### 37.4.5 Conversion control

Conversions can be performed as determined by CFG1[MODE] and SC1n[DIFF] as shown in the description of CFG1[MODE].

Conversions can be initiated by a software or hardware trigger.

In addition, the ADC module can be configured for:

- Low-power operation
- Long sample time
- Continuous conversion
- Hardware average
- Automatic compare of the conversion result to a software determined compare value

#### 37.4.5.1 Initiating conversions

A conversion is initiated:

- Following a write to SC1A, with SC1n[ADCH] not all 1's, if software triggered operation is selected, that is, when SC2[ADTRG]=0.
- Following a hardware trigger, or ADHWT event, if hardware triggered operation is selected, that is, SC2[ADTRG]=1, and a hardware trigger select event, ADHWTSn, has occurred. The channel and status fields selected depend on the active trigger select signal:
  - ADHWTSa active selects SC1A.
  - ADHWTSn active selects SC1n.
  - if neither is active, the off condition is selected

### Note

Selecting more than one ADHWTSn prior to a conversion completion will result in unknown results. To avoid this, select only one ADHWTSn prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled, that is, when SC3[ADCO] = 1.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation, that is, when SC2[ADTRG] = 0, continuous conversions begin after SC1A is written and continue until aborted. In hardware triggered operation, that is, when SC2[ADTRG] = 1 and one ADHWTSn event has occurred, continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions are completed. In software triggered operation, conversions begin after SC1A is written. In hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions are also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

#### 37.4.5.2 Completing conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, Rn. If the compare functions are disabled, this is indicated by setting of SC1n[COCO]. If hardware averaging is enabled, the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed. If the compare function is enabled, the respective SC1n[COCO] sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed and the compare condition is true. An interrupt is generated if the respective SC1n[AIEN] is high at the time that the respective SC1n[COCO] is set.

#### 37.4.5.3 Aborting conversions

Any conversion in progress is aborted when:

- Writing to SC1A while it is actively controlling a conversion, aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, a write to SC1A initiates a new conversion if SC1A[ADCH] is equal to a value other than all 1s. Writing to any of the SC1B–SC1n registers while that specific SC1B–SC1n register is actively controlling a conversion aborts the current conversion. The SC1(B-n) registers are not used for software trigger operation and therefore writes to the SC1(B-n) registers do not initiate a new conversion.
- A write to any ADC register besides the SC1A-SC1n registers occurs. This indicates that a change in mode of operation has occurred and the current conversion is therefore invalid.
- The MCU is reset or enters Low-Power Stop modes.
- The MCU enters Normal Stop mode with ADACK or Alternate Clock Sources not enabled.

When a conversion is aborted, the contents of the data registers, Rn, are not altered. The data registers continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset or Low-Power Stop modes, RA and Rn return to their reset states.

#### **37.4.5.4 Power control**

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, but the asynchronous clock output is disabled, that is CFG2[ADACKEN]=0, the ADACK clock generator also remains in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled, that is, CFG2[ADACKEN]=1, it remains active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting CFG1[ADLPC]. This results in a lower maximum value for  $f_{ADCK}$ .

#### **37.4.5.5 Sample time and total conversion time**

For short sample, that is, when CFG1[ADLSMP]=0, there is a 2-cycle adder for first conversion over the base sample time of four ADCK cycles. For high-speed conversions, that is, when CFG2[ADHSC]=1, there is an additional 2-cycle adder on any conversion. The table below summarizes sample times for the possible ADC configurations.

| ADC configuration |              |             | Sample time (ADCK cycles) |            |
|-------------------|--------------|-------------|---------------------------|------------|
| CFG1[ADLSMP]      | CFG2[ADLSTS] | CFG2[ADHSC] | First or Single           | Subsequent |
| 0                 | X            | 0           | 6                         | 4          |
| 1                 | 00           | 0           | 24                        |            |
| 1                 | 01           | 0           | 16                        |            |
| 1                 | 10           | 0           | 10                        |            |
| 1                 | 11           | 0           | 6                         |            |
| 0                 | X            | 1           | 8                         | 6          |
| 1                 | 00           | 1           | 26                        |            |
| 1                 | 01           | 1           | 18                        |            |
| 1                 | 10           | 1           | 12                        |            |
| 1                 | 11           | 1           | 8                         |            |

The total conversion time depends upon:

- The sample time as determined by CFG1[ADLSMP] and CFG2[ADLSTS]
- The MCU bus frequency
- The conversion mode, as determined by CFG1[MODE] and SC1n[DIFF]
- The high-speed configuration, that is, CFG2[ADHSC]
- The frequency of the conversion clock, that is,  $f_{ADCK}$ .

CFG2[ADHSC] is used to configure a higher clock input frequency. This will allow faster overall conversion times. To meet internal ADC timing requirements, CFG2[ADHSC] adds additional ADCK cycles. Conversions with CFG2[ADHSC]=1 take two more ADCK cycles. CFG2[ADHSC] must be used when the ADCLK exceeds the limit for CFG2[ADHSC]=0.

After the module becomes active, sampling of the input begins.

1. CFG1[ADLSMP] and CFG2[ADLSTS] select between sample times based on the conversion mode that is selected.
2. When sampling is completed, the converter is isolated from the input channel and a successive approximation algorithm is applied to determine the digital value of the analog signal.
3. The result of the conversion is transferred to Rn upon completion of the conversion algorithm.

If the bus frequency is less than  $f_{ADCK}$ , precise sample time for continuous conversions cannot be guaranteed when short sample is enabled, that is, when CFG1[ADLSMP]=0.

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by CFG1[ADICLK], and the divide ratio is specified by CFG1[ADIV].

The maximum total conversion time for all configurations is summarized in the equation below. See the following tables for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder} + \text{HSCAdder})$$

**Figure 37-157. Conversion time equation**

**Table 37-177. Single or first continuous time adder (SFCAdder)**

| CFG1[ADLSMP] | CFG2[ADACKEN] | CFG1[ADICLK] | Single or first continuous time adder (SFCAdder) |
|--------------|---------------|--------------|--|
| 1            | x             | 0x, 10       | 3 ADCK cycles + 5 bus clock cycles               |
| 1            | 1             | 11           | 3 ADCK cycles + 5 bus clock cycles <sup>1</sup>  |
| 1            | 0             | 11           | 5 μs + 3 ADCK cycles + 5 bus clock cycles        |
| 0            | x             | 0x, 10       | 5 ADCK cycles + 5 bus clock cycles               |
| 0            | 1             | 11           | 5 ADCK cycles + 5 bus clock cycles <sup>1</sup>  |
| 0            | 0             | 11           | 5 μs + 5 ADCK cycles + 5 bus clock cycles        |

1. To achieve this time, CFG2[ADACKEN] must be 1 for at least 5 μs prior to the conversion is initiated.

**Table 37-178. Average number factor (AverageNum)**

| SC3[AVGE] | SC3[AVGS] | Average number factor (AverageNum) |
|-----------|-----------|------------------------------------|
| 0         | xx        | 1                                  |
| 1         | 00        | 4                                  |
| 1         | 01        | 8                                  |

| CFG1[ADLSMP] | CFG2[ADLSTS] | Long sample time adder (LSTAdder) |
|--------------|--------------|-----------------------------------|
| 0            | xx           | 0 ADCK cycles                     |
| 1            | 00           | 20 ADCK cycles                    |
| 1            | 01           | 12 ADCK cycles                    |
| 1            | 10           | 6 ADCK cycles                     |
| 1            | 11           | 2 ADCK cycles                     |

**Table 37-181. High-speed conversion time adder (HSCAdder)**

| CFG2[ADHSC] | High-speed conversion time adder (HSCAdder) |
|-------------|---|
| 0           | 0 ADCK cycles                               |
| 1           | 2 ADCK cycles                               |

### Note

The ADCK frequency must be between  $f_{ADCK}$  minimum and  $f_{ADCK}$  maximum to meet ADC specifications.

## 37.4.5.6 Conversion time examples

The following examples use the [Figure 37-157](#), and the information provided in [Table 37-177](#) through [Table 37-181](#).

### 37.4.5.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is:

- 10-bit mode, with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 8 MHz
- Long sample time disabled
- High-speed conversion disabled

The conversion time for a single conversion is calculated by using the [Figure 37-157](#), and the information provided in [Table 37-177](#) through [Table 37-181](#). The table below lists the variables of [Figure 37-157](#).

**Table 37-182. Typical conversion time**

| Variable | Time                               |
|----------|------------------------------------|
| SFCAdder | 5 ADCK cycles + 5 bus clock cycles |

*Table continues on the next page...*

**Table 37-182. Typical conversion time (continued)**

| Variable   | Time           |
|------------|----------------|
| AverageNum | 1              |
| BCT        | 20 ADCK cycles |
| LSTAdder   | 0              |
| HSCAdder   | 0              |

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for a bus clock and an ADCK frequency equal to 8 MHz, the resulting conversion time is 3.75  $\mu$ s.

### 37.4.5.6.2 Long conversion time configuration

A configuration for long ADC conversion is:

- 16-bit differential mode with the bus clock selected as the input clock source
- The input clock divide-by-8 ratio selected
- Bus frequency of 8 MHz
- Long sample time enabled
- Configured for longest adder
- High-speed conversion disabled
- Average enabled for 32 conversions

The conversion time for this conversion is calculated by using the [Figure 37-157](#), and the information provided in [Table 37-177](#) through [Table 37-181](#). The following table lists the variables of the [Figure 37-157](#).

**Table 37-183. Typical conversion time**

| Variable   | Time                               |
|------------|------------------------------------|
| SFCAdder   | 3 ADCK cycles + 5 bus clock cycles |
| AverageNum | 32                                 |
| BCT        | 34 ADCK cycles                     |
| LSTAdder   | 20 ADCK cycles                     |
| HSCAdder   | 0                                  |

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock equal to 8 MHz and ADCK equal to 1 MHz, the resulting conversion time is 57.625  $\mu$ s, that is, AverageNum. This results in a total conversion time of 1.844 ms.

### 37.4.5.6.3 Short conversion time configuration

A configuration for short ADC conversion is:

- 8-bit Single-Ended mode with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 20 MHz
- Long sample time disabled
- High-speed conversion enabled

The conversion time for this conversion is calculated by using the [Figure 37-157](#), and the information provided in [Table 37-177](#) through [Table 37-181](#). The table below lists the variables of [Figure 37-157](#).

**Table 37-184. Typical conversion time**

| Variable   | Time                               |
|------------|------------------------------------|
| SFCAdder   | 5 ADCK cycles + 5 bus clock cycles |
| AverageNum | 1                                  |
| BCT        | 17 ADCK cycles                     |
| LSTAdder   | 0 ADCK cycles                      |
| HSCAdder   | 2                                  |

The resulting conversion time is generated using the parameters listed in in the preceding table. Therefore, for bus clock and ADCK frequency equal to 20 MHz, the resulting conversion time is 1.45  $\mu$ s.

### 37.4.5.7 Hardware average function

The hardware average function can be enabled by setting SC3[AVGE]=1 to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which can select 4, 8, 16, or 32 conversions to be averaged. While the hardware average function is in progress, SC2[ADACT] will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions have been completed. When hardware averaging is selected, the completion of a single conversion will not set SC1n[COCO].

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, Rn, and SC1n[COCO] is set. An ADC interrupt is generated upon the setting of SC1n[COCO] if the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

### Note

The hardware average function can perform conversions on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the hardware average is completed if SC1n[AIEN] is set.

## 37.4.6 Automatic compare function

The compare function can be configured to check whether the result is less than or greater-than-or-equal-to a single compare value, or, if the result falls within or outside a range determined by two compare values.

The compare mode is determined by SC2[ACFGT], SC2[ACREN], and the values in the compare value registers, CV1 and CV2. After the input is sampled and converted, the compare values in CV1 and CV2 are used as described in the following table. There are six Compare modes as shown in the following table.

**Table 37-185. Compare modes**

| SC2[ACFGT] | SC2[ACREN] | ADCCV1 relative to ADCCV2 | Function                           | Compare mode description   |
|------------|------------|---------------------------|------------------------------------|--|
| 0          | 0          | —                         | Less than threshold                | Compare true if the result is less than the CV1 registers.   |
| 1          | 0          | —                         | Greater than or equal to threshold | Compare true if the result is greater than or equal to CV1 registers.  |
| 0          | 1          | Less than or equal        | Outside range, not inclusive       | Compare true if the result is less than CV1 <b>Or</b> the result is greater than CV2.                          |
| 0          | 1          | Greater than              | Inside range, not inclusive        | Compare true if the result is less than CV1 <b>And</b> the result is greater than CV2.                         |
| 1          | 1          | Less than or equal        | Inside range, inclusive            | Compare true if the result is greater than or equal to CV1 <b>And</b> the result is less than or equal to CV2. |
| 1          | 1          | Greater than              | Outside range, inclusive           | Compare true if the result is greater than or equal to CV1 <b>Or</b> the result is less than or equal to CV2.  |

With SC2[ACREN] =1, and if the value of CV1 is less than or equal to the value of CV2, then setting SC2[ACFGT] will select a trigger-if-inside-compare-range inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than CV2, setting SC2[ACFGT] will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, SC1n[COCO] is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, SC1n[COCO] is not set and the conversion result data will not be transferred to the result register, Rn. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated when SC1n[COCO] is set and the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

### Note

The compare function can monitor the voltage on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the compare condition is met.

## 37.4.7 Calibration function

The ADC contains a self-calibration function that is required to achieve the specified accuracy.

Calibration must be run, or valid calibration values written, after any reset and before a conversion is initiated. The calibration function sets the offset calibration value, the minus-side calibration values, and the plus-side calibration values. The offset calibration value is automatically stored in the ADC offset correction register (OFS), and the plus-side and minus-side calibration values are automatically stored in the ADC plus-side and minus-side calibration registers, CLPx and CLMx. The user must configure the ADC correctly prior to calibration, and must generate the plus-side and minus-side gain calibration results and store them in the ADC plus-side gain register (PG) after the calibration function completes.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, and high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. For best calibration results:

- Set hardware averaging to maximum, that is, SC3[AVGE]=1 and SC3[AVGS]=11 for an average of 32
- Set ADC clock frequency  $f_{ADCK}$  less than or equal to 4 MHz
- $V_{REFH}=V_{DDA}$
- Calibrate at nominal voltage and temperature

The input channel, conversion mode continuous function, compare function, resolution mode, and differential/single-ended mode are all ignored during the calibration function.

To initiate calibration, the user sets SC3[*CAL*] and the calibration will automatically begin if the SC2[*ADTRG*] is 0. If SC2[*ADTRG*] is 1, SC3[*CAL*] will not get set and SC3[*CALF*] will be set. While calibration is active, no ADC register can be written and no stop mode may be entered, or the calibration routine will be aborted causing SC3[*CAL*] to clear and SC3[*CALF*] to set. At the end of a calibration sequence, SC1n[*COCO*] will be set. SC1n[*AIEN*] can be used to allow an interrupt to occur at the end of a calibration sequence. At the end of the calibration routine, if SC3[*CALF*] is not set, the automatic calibration routine is completed successfully.

To complete calibration, the user must generate the gain calibration values using the following procedure:

1. Initialize or clear a 16-bit variable in RAM.
2. Add the plus-side calibration results CLP0, CLP1, CLP2, CLP3, CLP4, and CLPS to the variable.
3. Divide the variable by two.
4. Set the MSB of the variable.
5. The previous two steps can be achieved by setting the carry bit, rotating to the right through the carry bit on the high byte and again on the low byte.
6. Store the value in the plus-side gain calibration register PG.
7. Repeat the procedure for the minus-side gain calibration value.

When calibration is complete, the user may reconfigure and use the ADC as desired. A second calibration may also be performed, if desired, by clearing and again setting SC3[*CAL*].

Overall, the calibration routine may take as many as 14k ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen. For an 8 MHz clock source, this length amounts to about 1.7 ms. To reduce this latency, the calibration values, which are offset, plus-side and minus-side gain, and plus-side and minus-side calibration values, may be stored in flash memory after an initial calibration and recovered prior to the first ADC conversion. This method can reduce the calibration latency to 20 register store operations on all subsequent power, reset, or Low-Power Stop mode recoveries.

Further information on the calibration procedure can be found in the Calibration section of [AN3949: ADC16 Calibration Procedure and Programmable Delay Block Synchronization](#).

### 37.4.8 User-defined offset function

OFS contains the user-selected or calibration-generated offset error correction value.

This register is a 2's complement, left-justified. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

The formatting of the OFS is different from the data result register, Rn, to preserve the resolution of the calibration value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8-bit single-ended mode, OFS[14:7] are subtracted from D[7:0]; OFS[15] indicates the sign (negative numbers are effectively added to the result) and OFS[6:0] are ignored. The same bits are used in 9-bit differential mode because OFS[15] indicates the sign bit, which maps to D[8]. For 16-bit differential mode, OFS[15:0] are directly subtracted from the conversion result data D[15:0]. In 16-bit single-ended mode, there is no field in the OFS corresponding to the least significant result D[0], so odd values, such as -1 or +1, cannot be subtracted from the result.

OFS is automatically set according to calibration requirements once the self-calibration sequence is done, that is, SC3[CAL] is cleared. The user may write to OFS to override the calibration result if desired. If the OFS is written by the user to a value that is different from the calibration value, the ADC error specifications may not be met. Storing the value generated by the calibration function in memory before overwriting with a user-specified value is recommended.

#### Note

There is an effective limit to the values of offset that can be set by the user. If the magnitude of the offset is too high, the results of the conversions will cap off at the limits.

The offset calibration function may be employed by the user to remove application offsets or DC bias values. OFS may be written with a number in 2's complement format and this offset will be subtracted from the result, or hardware averaged value. To add an offset, store the negative offset in 2's complement format and the effect will be an addition. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value. The minimum value for single-ended conversions is 0x0000; for a differential conversion it is 0x8000.

To preserve accuracy, the calibrated offset value initially stored in OFS must be added to the user-defined offset. For applications that may change the offset repeatedly during operation, store the initial offset calibration value in flash so it can be recovered and added to any user offset adjustment value and the sum stored in OFS.

### 37.4.9 Temperature sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs.

The following equation provides an approximate transfer function of the temperature sensor.

$$\text{Temp} = 25 - \left( \left( V_{\text{TEMP}} - V_{\text{TEMP25}} \right) \div m \right)$$

**Figure 37-158. Approximate transfer function of the temperature sensor**

where:

- $V_{\text{TEMP}}$  is the voltage of the temperature sensor channel at the ambient temperature.
- $V_{\text{TEMP25}}$  is the voltage of the temperature sensor channel at 25 °C.
- $m$  is referred as temperature sensor slope in the device data sheet. It is the hot or cold voltage versus temperature slope in  $V/^\circ\text{C}$ .

For temperature calculations, use the  $V_{\text{TEMP25}}$  and temperature sensor slope values from the ADC Electricals table.

In application code, the user reads the temperature sensor channel, calculates  $V_{\text{TEMP}}$ , and compares to  $V_{\text{TEMP25}}$ . If  $V_{\text{TEMP}}$  is greater than  $V_{\text{TEMP25}}$  the cold slope value is applied in the preceding equation. If  $V_{\text{TEMP}}$  is less than  $V_{\text{TEMP25}}$ , the hot slope value is applied in the preceding equation. ADC Electricals table may only specify one temperature sensor slope value. In that case, the user could use the same slope for the calculation across the operational temperature range.

For more information on using the temperature sensor, see the application note titled *Temperature Sensor for the HCS08 Microcontroller Family* (document AN3031).

### 37.4.10 MCU wait mode operation

Wait mode is a lower-power consumption Standby mode from which recovery is fast because the clock sources remain active.

If a conversion is in progress when the MCU enters Wait mode, it continues until completion. Conversions can be initiated while the MCU is in Wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two; and ADACK are available as conversion clock sources while in Wait mode. The use of ALTCLK as the conversion clock source in Wait is dependent on the definition of ALTCLK for this MCU. See the Chip Configuration information on ALTCLK specific to this MCU.

If the compare and hardware averaging functions are disabled, a conversion complete event sets SC1n[COCO] and generates an ADC interrupt to wake the MCU from Wait mode if the respective ADC interrupt is enabled, that is, when SC1n[AIEN]=1. If the hardware averaging function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from Wait mode unless a new conversion is initiated by the hardware trigger.

## 37.4.11 MCU Normal Stop mode operation

Stop mode is a low-power consumption Standby mode during which most or all clock sources on the MCU are disabled.

### 37.4.11.1 Normal Stop mode with ADACK disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its Idle state. The contents of the ADC registers, including Rn, are unaffected by Normal Stop mode. After exiting from Normal Stop mode, a software or hardware trigger is required to resume conversions.

### 37.4.11.2 Normal Stop mode with ADACK enabled

If ADACK is selected as the conversion clock, the ADC continues operation during Normal Stop mode. See the chip-specific ADC information for configuration information for this device.

If a conversion is in progress when the MCU enters Normal Stop mode, it continues until completion. Conversions can be initiated while the MCU is in Normal Stop mode by means of the hardware trigger or if continuous conversions are enabled.

If the compare and hardware averaging functions are disabled, a conversion complete event sets  $SC1n[COCO]$  and generates an ADC interrupt to wake the MCU from Normal Stop mode if the respective ADC interrupt is enabled, that is, when  $SC1n[AIEN]=1$ . The result register,  $Rn$ , will contain the data from the first completed conversion that occurred during Normal Stop mode. If the hardware averaging function is enabled,  $SC1n[COCO]$  will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled,  $SC1n[COCO]$  will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare is not true, the ADC will return to its idle state and cannot wake the MCU from Normal Stop mode unless a new conversion is initiated by another hardware trigger.

### 37.4.12 MCU Low-Power Stop mode operation

The ADC module is automatically disabled when the MCU enters Low-Power Stop mode.

All module registers contain their reset values following exit from Low-Power Stop mode. Therefore, the module must be re-enabled and re-configured following exit from Low-Power Stop mode.

#### NOTE

For the chip specific modes of operation, see the power management information for the device.

## 37.5 Initialization information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module.

The user can configure the module for 16-bit, 12-bit, 10-bit, or 8-bit single-ended resolution or 16-bit, 13-bit, 11-bit, or 9-bit differential resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. For information used in this example, refer to [Table 37-180](#), [Table 37-181](#), and [Table 37-182](#).

## Note

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

### 37.5.1 ADC module initialization example

#### 37.5.1.1 Initialization sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is:

1. Calibrate the ADC by following the calibration instructions in [Calibration function](#).
2. Update CFG to select the input clock source and the divide ratio used to generate ADCK. This register is also used for selecting sample time and low-power configuration.
3. Update SC2 to select the conversion trigger, hardware or software, and compare function options, if enabled.
4. Update SC3 to select whether conversions will be continuous or completed only once (ADCO) and whether to perform hardware averaging.
5. Update SC1:SC1n registers to select whether conversions will be single-ended or differential and to enable or disable conversion complete interrupts. Also, select the input channel which can be used to perform conversions.
6. Update the PGA register to enable or disable PGA and configure appropriate gain. This register is also used to select Power Mode and to check whether the module is chopper-stabilized.

#### 37.5.1.2 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low-power with a long sample time on input channel 1, where ADCK is derived from the bus clock divided by 1.

**CFG1 = 0x98 (%10011000)**

### Initialization information

|         |        |    |   |
|---------|--------|----|---|
| Bit 7   | ADLPC  | 1  | Configures for low power, lowers maximum clock speed.                       |
| Bit 6:5 | ADIV   | 00 | Sets the ADCK to the input clock ÷ 1.                                       |
| Bit 4   | ADLSMP | 1  | Configures for long sample time.  |
| Bit 3:2 | MODE   | 10 | Selects the single-ended 10-bit conversion, differential 11-bit conversion. |
| Bit 1:0 | ADICLK | 00 | Selects the bus clock.  |

### SC2 = 0x00 (%00000000)

|         |        |    |  |
|---------|--------|----|--|
| Bit 7   | ADACT  | 0  | Flag indicates if a conversion is in progress.   |
| Bit 6   | ADTRG  | 0  | Software trigger selected.   |
| Bit 5   | ACFE   | 0  | Compare function disabled.   |
| Bit 4   | ACFGT  | 0  | Not used in this example.  |
| Bit 3   | ACREN  | 0  | Compare range disabled.  |
| Bit 2   | DMAEN  | 0  | DMA request disabled.  |
| Bit 1:0 | REFSEL | 00 | Selects default voltage reference pin pair (External pins V <sub>REFH</sub> and V <sub>REFL</sub> ). |

### SC1A = 0x41 (%01000001)

|         |      |       |  |
|---------|------|-------|--|
| Bit 7   | COCO | 0     | Read-only flag which is set when a conversion completes. |
| Bit 6   | AIEN | 1     | Conversion complete interrupt enabled.                   |
| Bit 5   | DIFF | 0     | Single-ended conversion selected.                        |
| Bit 4:0 | ADCH | 00001 | Input channel 1 selected as ADC input channel.           |

### RA = 0xxx

Holds results of conversion.

### CV = 0xxx

Holds compare value when compare function enabled.

**Figure 37-159. Initialization flowchart example**

## 37.6 Application information

The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an ADC.

For guidance on selecting optimum external component values and converter parameters see [AN4373: Cookbook for SAR ADC Measurements](#).

### 37.6.1 External pins and routing

#### 37.6.1.1 Analog supply pins

Depending on the device, the analog power and ground supplies,  $V_{DDA}$  and  $V_{SSA}$ , of the ADC module are available as:

- $V_{DDA}$  and  $V_{SSA}$  available as separate pins—When available on a separate pin, both  $V_{DDA}$  and  $V_{SSA}$  must be connected to the same voltage potential as their corresponding MCU digital supply,  $V_{DD}$  and  $V_{SS}$ , and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.
- $V_{SSA}$  is shared on the same pin as the MCU digital  $V_{SS}$ .
- $V_{SSA}$  and  $V_{DDA}$  are shared with the MCU digital supply pins—In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the  $V_{SSA}$  pin. This must be the only ground connection between these supplies, if possible.  $V_{SSA}$  makes a good single point ground location.

#### 37.6.1.2 Analog voltage reference pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs used by the converter:

- $V_{REFSH}$  is the high reference voltage for the converter.
- $V_{REFSL}$  is the low reference voltage for the converter.

The ADC can be configured to accept one of two voltage reference pairs for  $V_{REFSH}$  and  $V_{REFSL}$ . Each pair contains a positive reference and a ground reference. The two pairs are external,  $V_{REFH}$  and  $V_{REFL}$  and alternate,  $V_{ALTH}$  and  $V_{ALTTL}$ . These voltage references are

selected using SC2[REFSEL]. The alternate voltage reference pair,  $V_{ALTH}$  and  $V_{ALTLL}$ , may select additional external pins or internal sources based on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

In some packages, the external or alternate pairs are connected in the package to  $V_{DDA}$  and  $V_{SSA}$ , respectively. One of these positive references may be shared on the same pin as  $V_{DDA}$  on some devices. One of these ground references may be shared on the same pin as  $V_{SSA}$  on some devices.

If externally available, the positive reference may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source to a level between the minimum Ref Voltage High and the  $V_{DDA}$  potential. The positive reference must never exceed  $V_{DDA}$ . If externally available, the ground reference must be connected to the same voltage potential as  $V_{SSA}$ . The voltage reference pairs must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the  $V_{REFH}$  and  $V_{REFL}$  loop. The best external component to meet this current demand is a 0.1  $\mu\text{F}$  capacitor with good high-frequency characteristics. This capacitor is connected between  $V_{REFH}$  and  $V_{REFL}$  and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum, that is, parasitic only.

### 37.6.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01  $\mu\text{F}$  capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used, they must be placed as near as possible to the package pins and be referenced to  $V_{SSA}$ .

For proper conversion, the input voltage must fall between  $V_{REFH}$  and  $V_{REFL}$ . If the input is equal to or exceeds  $V_{REFH}$ , the converter circuit converts the signal to 0xFFF, which is full scale 12-bit representation, 0x3FF, which is full scale 10-bit representation, or 0xFF, which is full scale 8-bit representation. If the input is equal to or less than  $V_{REFL}$ , the converter circuit converts it to 0x000. Input voltages between  $V_{REFH}$  and  $V_{REFL}$  are straight-line linear conversions. There is a brief current associated with  $V_{REFL}$  when the sampling capacitor is charging.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins must not be transitioning during conversions.

## 37.6.2 Sources of error

### 37.6.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy.

$$RAS + RADIN = SC / (FMAX * NUMTAU * CADIN)$$

**Figure 37-160. Sampling equation**

Where:

RAS = External analog source resistance

SC = Number of ADCK cycles used during sample window

CADIN = Internal ADC input capacitance

NUMTAU =  $-\ln(\text{LSBERR} / 2^N)$

LSBERR = value of acceptable sampling error in LSBs

N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode or 16 in 16-bit mode

Higher source resistances or higher-accuracy sampling is possible by setting CFG1[ADLSMP] and changing CFG2[ADLSTS] to increase the sample window, or decreasing ADCK frequency to increase sample time.

### 37.6.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance,  $R_{AS}$ , is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $V_{REFH} / (4 \times I_{LEAK} \times 2^N)$  for less than 1/4 LSB leakage error, where N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode, or 16 in 16-bit mode.

### 37.6.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{REFH}}$  to  $V_{\text{REFL}}$ .
- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- If inductive isolation is used from the primary supply, an additional 1  $\mu\text{F}$  capacitor is placed from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- $V_{\text{SSA}}$ , and  $V_{\text{REFL}}$ , if connected, is connected to  $V_{\text{SS}}$  at a quiet point in the ground plane.
- Operate the MCU in Wait or Normal Stop mode before initiating (hardware-triggered conversions) or immediately after initiating (hardware- or software-triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to SC1 with a Wait instruction or Stop instruction.
  - For Normal Stop mode operation, select ADACK as the clock source. Operation in Normal Stop reduces  $V_{\text{DD}}$  noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive  $V_{\text{DD}}$  noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in Wait or Normal Stop mode, or I/O activity cannot be halted, the following actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu\text{F}$  capacitor ( $C_{\text{AS}}$ ) on the selected input channel to  $V_{\text{REFL}}$  or  $V_{\text{SSA}}$ . This improves noise issues, but affects the sample rate based on the external analog source resistance.
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1 LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock, that is, ADACK, and averaging. Noise that is synchronous to ADCK cannot be averaged out.

### 37.6.2.4 Code width and quantization error

The ADC quantizes the ideal straight-line transfer function into 65536 steps in the 16-bit mode. Each step ideally has the same height, that is, 1 code, and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N-bit converter, where N can be 16, 12, 10, or 8, defined as 1 LSB, is:

$$1\text{LSB} = (V_{\text{REFH}}) / 2^N$$

**Figure 37-161. Ideal code width for an N-bit converter**

There is an inherent quantization error due to the digitization of the result. For 8-bit, 10-bit, or 12-bit conversions, the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be  $\pm 1/2$  LSB in 8-bit, 10-bit, or 12-bit modes. As a consequence, however, the code width of the first (0x000) conversion is only  $1/2$  LSB and the code width of the last (0xFF or 0x3FF) is 1.5 LSB.

For 16-bit conversions, the code transitions only after the full code width is present, so the quantization error is -1 LSB to 0 LSB and the code width of each step is 1 LSB.

### 37.6.2.5 Linearity errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors, but the system designers must be aware of these errors because they affect overall accuracy:

- Zero-scale error ( $E_{ZS}$ ), sometimes called offset: This error is defined as the difference between the actual code width of the first conversion and the ideal code width. This is  $1/2$  LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 LSB) is used.
- Full-scale error ( $E_{FS}$ ): This error is defined as the difference between the actual code width of the last conversion and the ideal code width. This is 1.5 LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1 LSB) is used.
- Differential non-linearity (DNL): This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.

- **Integral non-linearity (INL):** This error is defined as the highest-value or absolute value that the running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- **Total unadjusted error (TUE):** This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

### 37.6.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error:

- **Code jitter:** Code jitter occurs when a given input voltage converts to one of the two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code, and vice-versa. However, even small amounts of system noise can cause the converter to be indeterminate, between two codes, for a range of input voltages around the transition voltage.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally, the techniques discussed in [Noise-induced errors](#) reduces this error.

- **Non-monotonicity:** Non-monotonicity occurs when, except for code jitter, the converter converts to a lower code for a higher input voltage.
- **Missing codes:** Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

# Chapter 38

## Comparator (CMP)

### 38.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference  $V_{in}$  into 64 voltage levels. A 6-bit digital signal input selects the output voltage level, which varies from  $V_{in}$  to  $V_{in}/64$ .  $V_{in}$  can be selected from two voltage sources,  $V_{in1}$  and  $V_{in2}$ . The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

#### 38.1.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control

- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer
- Functional in all modes of operation
- The window and filter functions are not available in the following modes:
  - Stop
  - VLPS
  - LLS
  - VLLSx

### 38.1.2 6-bit DAC key features

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

### 38.1.3 ANMUX key features

- Two 8-to-1 channel mux
- Operational over the entire supply range

### 38.1.4 CMP, DAC and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

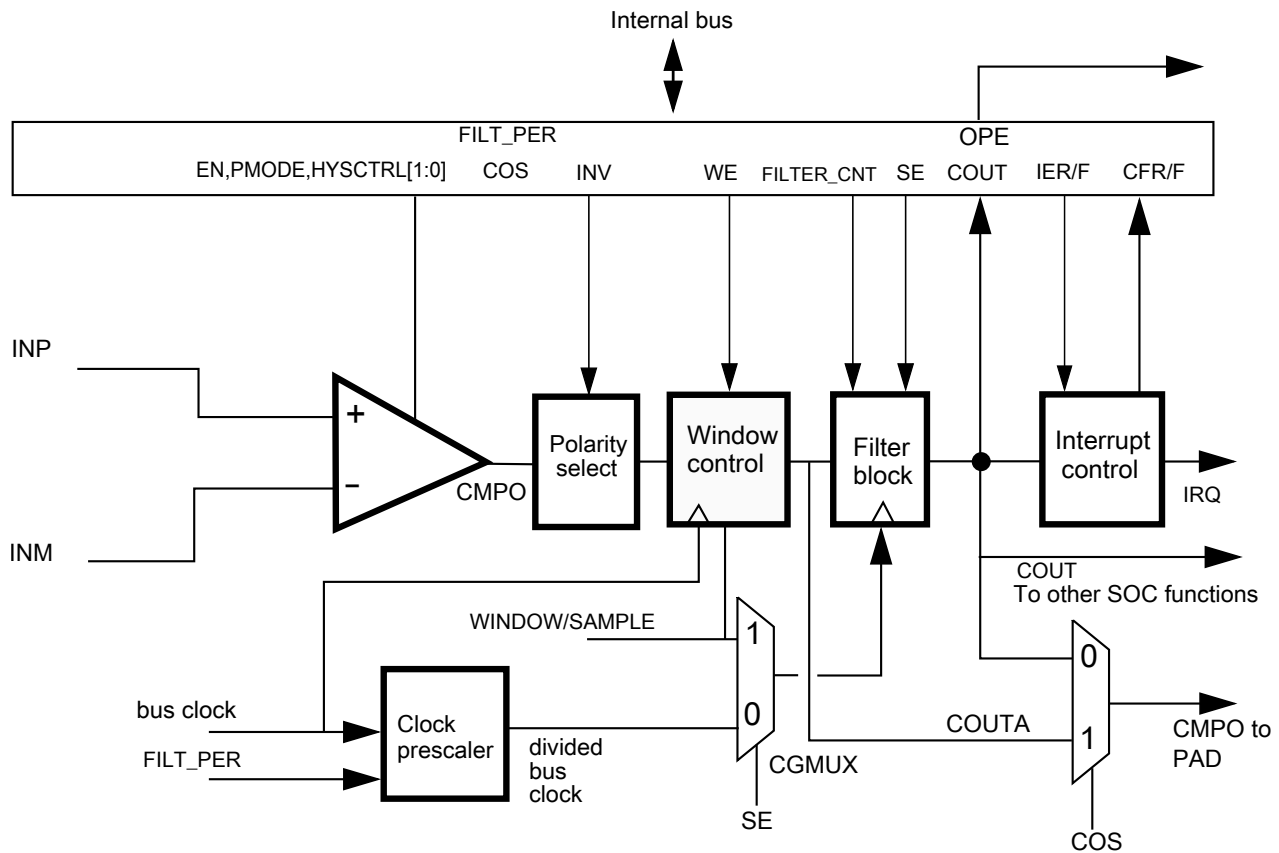

Figure 38-1. CMP, DAC and ANMUX block diagram

### 38.1.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

**Figure 38-2. Comparator module block diagram**

In the CMP block diagram:

- The Window Control block is bypassed when  $CR1[WE] = 0$
- If  $CR1[WE] = 1$ , the comparator output will be sampled on every bus clock when  $WINDOW=1$  to generate  $COUTA$ . Sampling does NOT occur when  $WINDOW = 0$ .
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and  $CR0[FILTER\_CNT]$  is set to  $0x01$ .
- The Filter block filters based on multiple samples when the filter is bypassed and  $CR0[FILTER\_CNT]$  is set greater than  $0x01$ .
  - If  $CR1[SE] = 1$ , the external  $SAMPLE$  input is used as sampling clock
  - If  $CR1[SE] = 0$ , the divided bus clock is used as sampling clock

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.
- CR1[WE] and CR1[SE] are mutually exclusive.

## 38.2 Memory map/register definitions

### CMP memory map

| Absolute address (hex) | Register name                              | Width (in bits) | Access | Reset value | Section/page                |

## 38.3 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM.

CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].

### 38.3.1 CMP functional modes

There are the following main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER\_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

**Table 38-36. Comparator sample/filter controls**

| Mode # | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation   |
|--------|---------|---------|---------|-----------------|---------------|---|
| 1      | 0       | X       | X       | X               | X             | <b>Disabled</b><br>See the <a href="#">Disabled mode (# 1)</a> .  |
| 2A     | 1       | 0       | 0       | 0x00            | X             | <b>Continuous Mode</b><br>See the <a href="#">Continuous mode (#s 2A &amp; 2B)</a> .  |
| 2B     | 1       | 0       | 0       | X               | 0x00          |   |

| 4B     | 1       | 0       | 0       | > 0x01          | > 0x00        |   |
| 5A     | 1       | 1       | 0       | 0x00            | X             | <b>Windowed mode</b><br>Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA.<br>See the <a href="#">Windowed mode (#s 5A &amp; 5B)</a> .  |
| 5B     | 1       | 1       | 0       | X               | 0x00          |   |
| 6      | 1       | 1       | 0       | 0x01            | 0x01–0xFF     | <b>Windowed/Resampled mode</b><br>Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled on an interval determined by FILT_PER to generate COUT.<br>See the <a href="#">Windowed/Resampled mode (# 6)</a> . |

Table continues on the next page...

**Table 38-36. Comparator sample/filter controls (continued)**

| Mode #   | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation   |
|--|---------|---------|---------|-----------------|---------------|---|
| 7  | 1       | 1       | 0       | > 0x01          | 0x01–0xFF     | <p><b>Windowed/Filtered mode</b></p> <p>Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT.</p> <p>See the <a href="#">Windowed/Filtered mode (#7)</a>.</p> |
| All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER_CNT], and FPR[FILT_PER] are illegal. |         |         |         |                 |               |   |

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

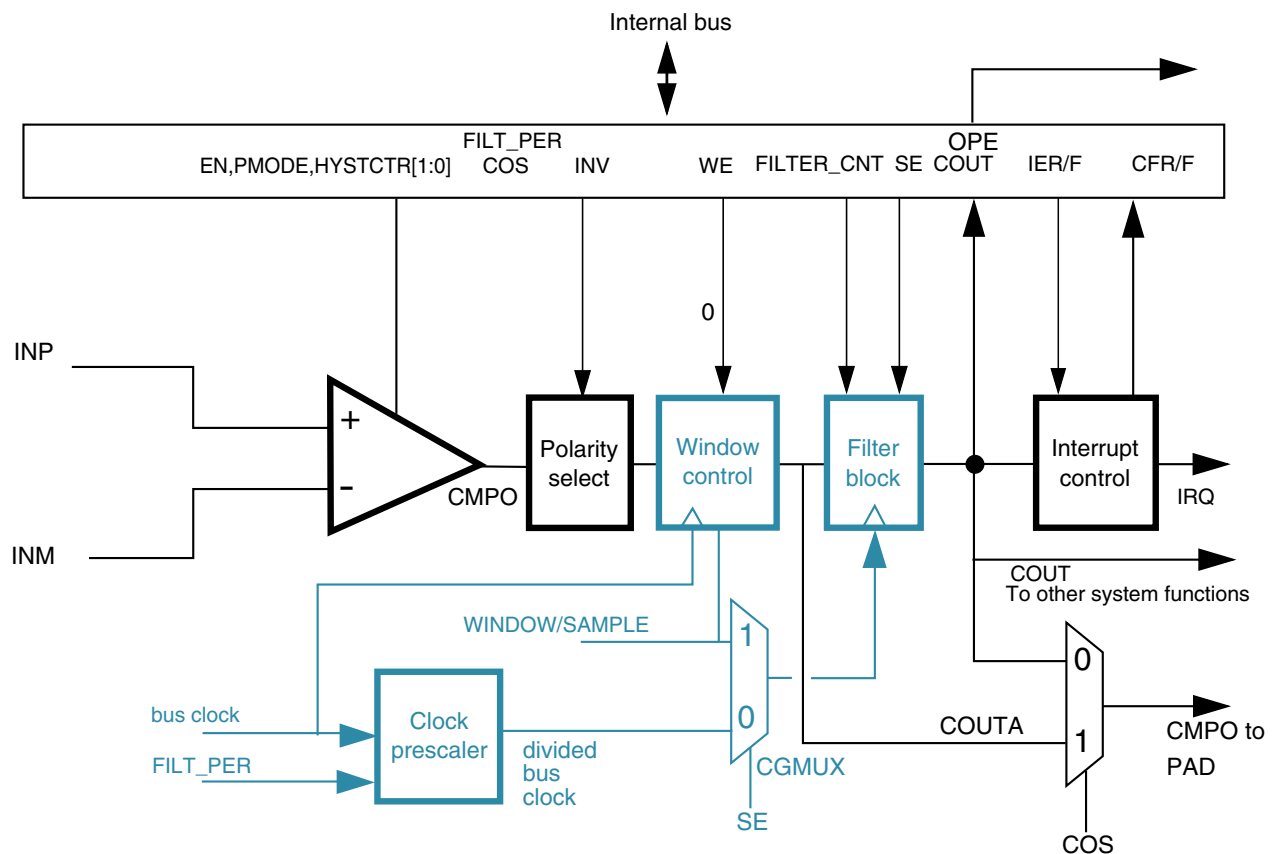

**Note**

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER\_CNT]=0x00. This resets the filter to a known state.

**38.3.1.1 Disabled mode (# 1)**

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

### 38.3.1.2 Continuous mode (#s 2A & 2B)

**Figure 38-33. Comparator operation in Continuous mode**

#### NOTE

See the chip configuration section for the source of sample/window input.

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unlocked mode. COUT and COUTA are identical.

For control configurations which result in disabling the filter block, see the [Filter Block Bypass Logic](#) diagram.

### 38.3.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

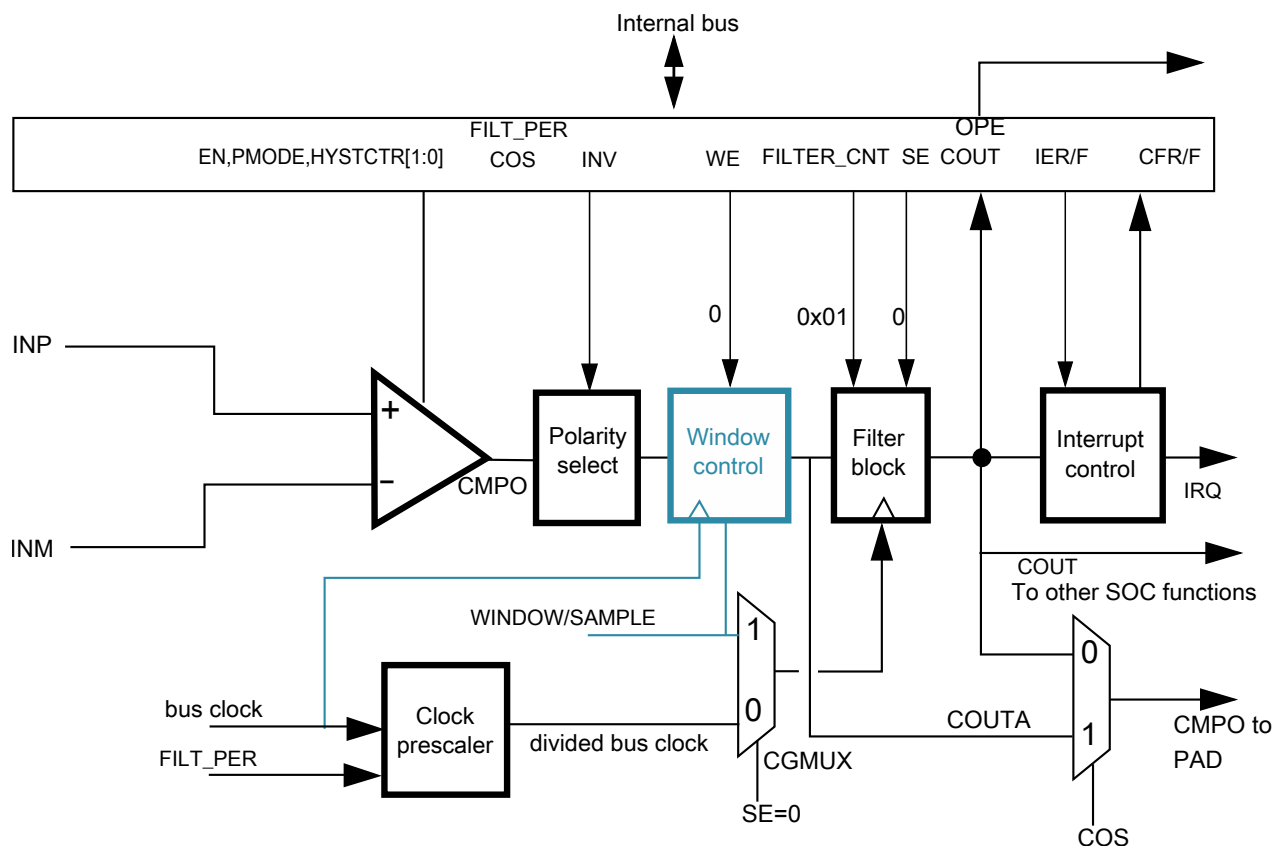

**Figure 38-34. Sampled, Non-Filtered (# 3A): sampling point externally driven**

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

**Figure 38-35. Sampled, Non-Filtered (# 3B): sampling interval internally derived**

### 38.3.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now,  $CR0[FILTER\_CNT] > 1$ , which activates filter operation.

Figure 38-36. Sampled, Filtered (# 4A): sampling point externally driven

**Figure 38-37. Sampled, Filtered (# 4B): sampling point internally derived**

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now,  $CR0[FILTER\_CNT] > 1$ , which activates filter operation.

### 38.3.1.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

#### NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

Figure 38-38. Windowed mode operation

Figure 38-39. Windowed mode

For control configurations which result in disabling the filter block, see [Filter Block Bypass Logic](#) diagram.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

### 38.3.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 38-38, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

Figure 38-40. Windowed/resampled mode operation

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT\_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of CR0[FILTER\_CNT] must be 1.

### 38.3.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function +  $((CR0[FILTER\_CNT] * FPR[FILT\_PER]) + 1) * \text{bus clock}$  for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

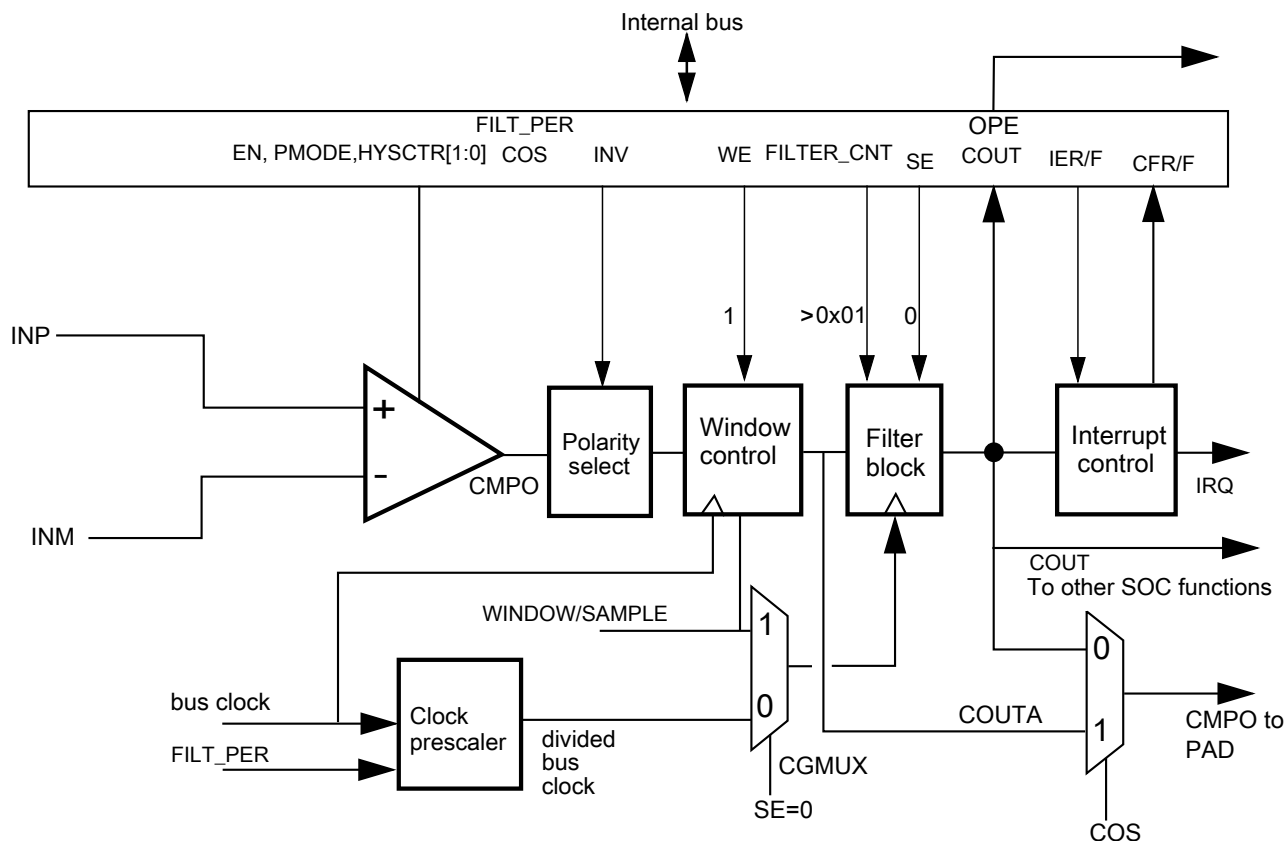

Figure 38-41. Windowed/Filtered mode

## 38.3.2 Power modes

### 38.3.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.

### 38.3.2.2 Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

### 38.3.2.3 Low-Leakage mode operation

When the chip is in Low-Leakage modes:

- The CMP module is partially functional and is limited to Low-Speed mode, regardless of CR1[PMODE] setting
- Windowed, Sampled, and Filtered modes are not supported
- The CMP output pin is latched and does not reflect the compare output state.

The positive- and negative-input voltage can be supplied from external pins or the DAC output. The MCU can be brought out of the Low-Leakage mode if a compare event occurs and the CMP interrupt is enabled. After wakeup from low-leakage modes, the CMP module is in the reset state except for SCR[CFF] and SCR[CFR].

### 38.3.3 Startup and operation

A typical startup sequence is listed here.

- The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the [Low-pass filter](#).
- During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF]

to reflect an input change or a configuration change to one of the components involved in the data path.

- When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

### 38.3.4 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT.

Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT\_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

#### 38.3.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER\_CNT] > 0x01 and
- Setting FPR[FILT\_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT\_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed. In other words, SCR[COUT] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT\_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

### Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CR0[FILTER\_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed.

#### 38.3.4.2 Latency issues

The value of FPR[FILT\_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER\_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER\_CNT].

The values of FPR[FILT\_PER] or SAMPLE period and CR0[FILTER\_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER\_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

**Table 38-37. Comparator sample/filter maximum latencies**

| Mode # | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation                  | Maximum latency <sup>1</sup>   |
|--------|---------|---------|---------|-----------------|---------------|----------------------------|--|
| 1      | 0       | X       | X       | X               | X             | Disabled                   | N/A  |
| 2A     | 1       | 0       | 0       | 0x00            | X             | Continuous Mode            | T <sub>PD</sub>  |
| 2B     | 1       | 0       | 0       | X               | 0x00          |                            |  |
| 3A     | 1       | 0       | 1       | 0x01            | X             | Sampled, Non-Filtered mode | T <sub>PD</sub> + T <sub>SAMPLE</sub> + T <sub>per</sub>                                   |
| 3B     | 1       | 0       | 0       | 0x01            | > 0x00        |                            | T <sub>PD</sub> + (FPR[FILT_PER] * T <sub>per</sub> ) + T <sub>per</sub>                   |
| 4A     | 1       | 0       | 1       | > 0x01          | X             | Sampled, Filtered mode     | T <sub>PD</sub> + (CR0[FILTER_CNT] * T <sub>SAMPLE</sub> ) + T <sub>per</sub>              |
| 4B     | 1       | 0       | 0       | > 0x01          | > 0x00        |                            | T <sub>PD</sub> + (CR0[FILTER_CNT] * FPR[FILT_PER] x T <sub>per</sub> ) + T <sub>per</sub> |

Table continues on the next page...

**Table 38-37. Comparator sample/filter maximum latencies (continued)**

| Mode # | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation                 | Maximum latency <sup>1</sup>  |
|--------|---------|---------|---------|-----------------|---------------|---------------------------|---|
| 5A     | 1       | 1       | 0       | 0x00            | X             | Windowed mode             | $T_{PD} + T_{per}$  |
| 5B     | 1       | 1       | 0       | X               | 0x00          |                           | $T_{PD} + T_{per}$  |
| 6      | 1       | 1       | 0       | 0x01            | 0x01 - 0xFF   | Windowed / Resampled mode | $T_{PD} + (FPR[FILT\_PER] * T_{per}) + 2T_{per}$                    |
| 7      | 1       | 1       | 0       | > 0x01          | 0x01 - 0xFF   | Windowed / Filtered mode  | $T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + 2T_{per}$ |

1.  $T_{PD}$  represents the intrinsic delay of the analog component plus the polarity select logic.  $T_{SAMPLE}$  is the clock period of the external sample clock.  $T_{per}$  is the period of the bus clock.

## 38.4 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both.

The following table gives the conditions in which the interrupt request is asserted and deasserted.

| When   | Then                                |
|--|-------------------------------------|
| SCR[IER] and SCR[CFR] are set                                  | The interrupt request is asserted   |
| SCR[IEF] and SCR[CFF] are set                                  | The interrupt request is asserted   |
| SCR[IER] and SCR[CFR] are cleared for a rising-edge interrupt  | The interrupt request is deasserted |
| SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt | The interrupt request is deasserted |

## 38.5 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

## 38.6 Digital-to-analog converter

The figure found here shows the block diagram of the DAC module.

It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DACCR). Its supply reference source can be selected from two sources  $V_{in1}$  and  $V_{in2}$ . The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

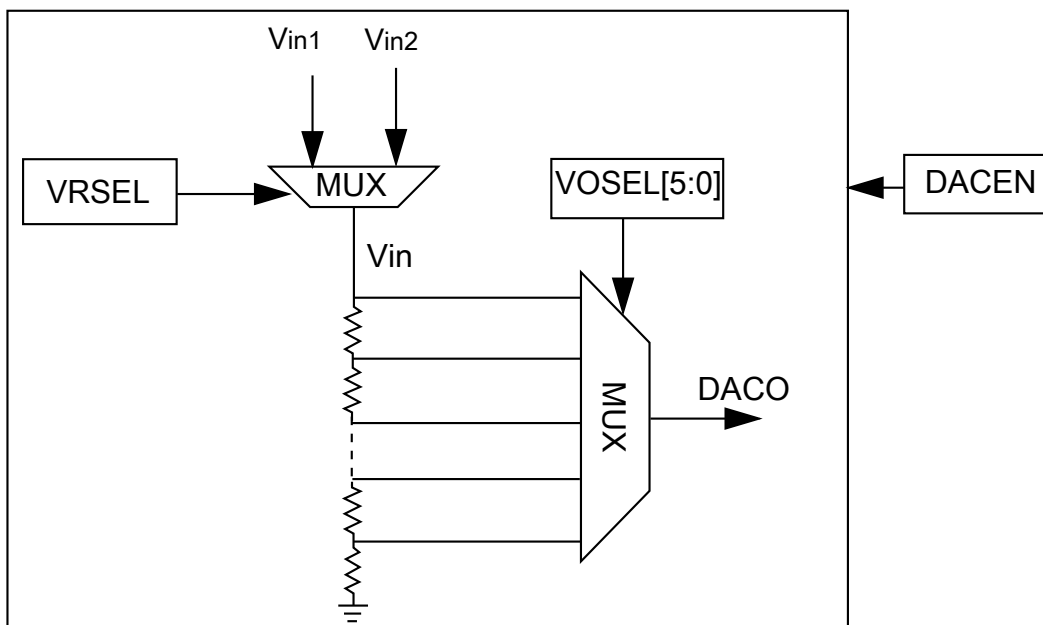

Figure 38-42. 6-bit DAC block diagram

## 38.7 DAC functional description

This section provides DAC functional description information.

### 38.7.1 Voltage reference source select

- $V_{in1}$  connects to the primary voltage source as supply reference of 64 tap resistor ladder
- $V_{in2}$  connects to an alternate voltage source

## 38.8 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

## 38.9 DAC clocks

This module has a single clock input, the bus clock.

## 38.10 DAC interrupts

This module has no interrupts.

## Chapter 39

# 12-bit Digital-to-Analog Converter (DAC)

### 39.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

### 39.2 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from  $1/4096 V_{in}$  to  $V_{in}$ , and the step is  $1/4096 V_{in}$ , where  $V_{in}$  is the input voltage.
- $V_{in}$  can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

### 39.3 Block diagram

The block diagram of the DAC module is as follows:

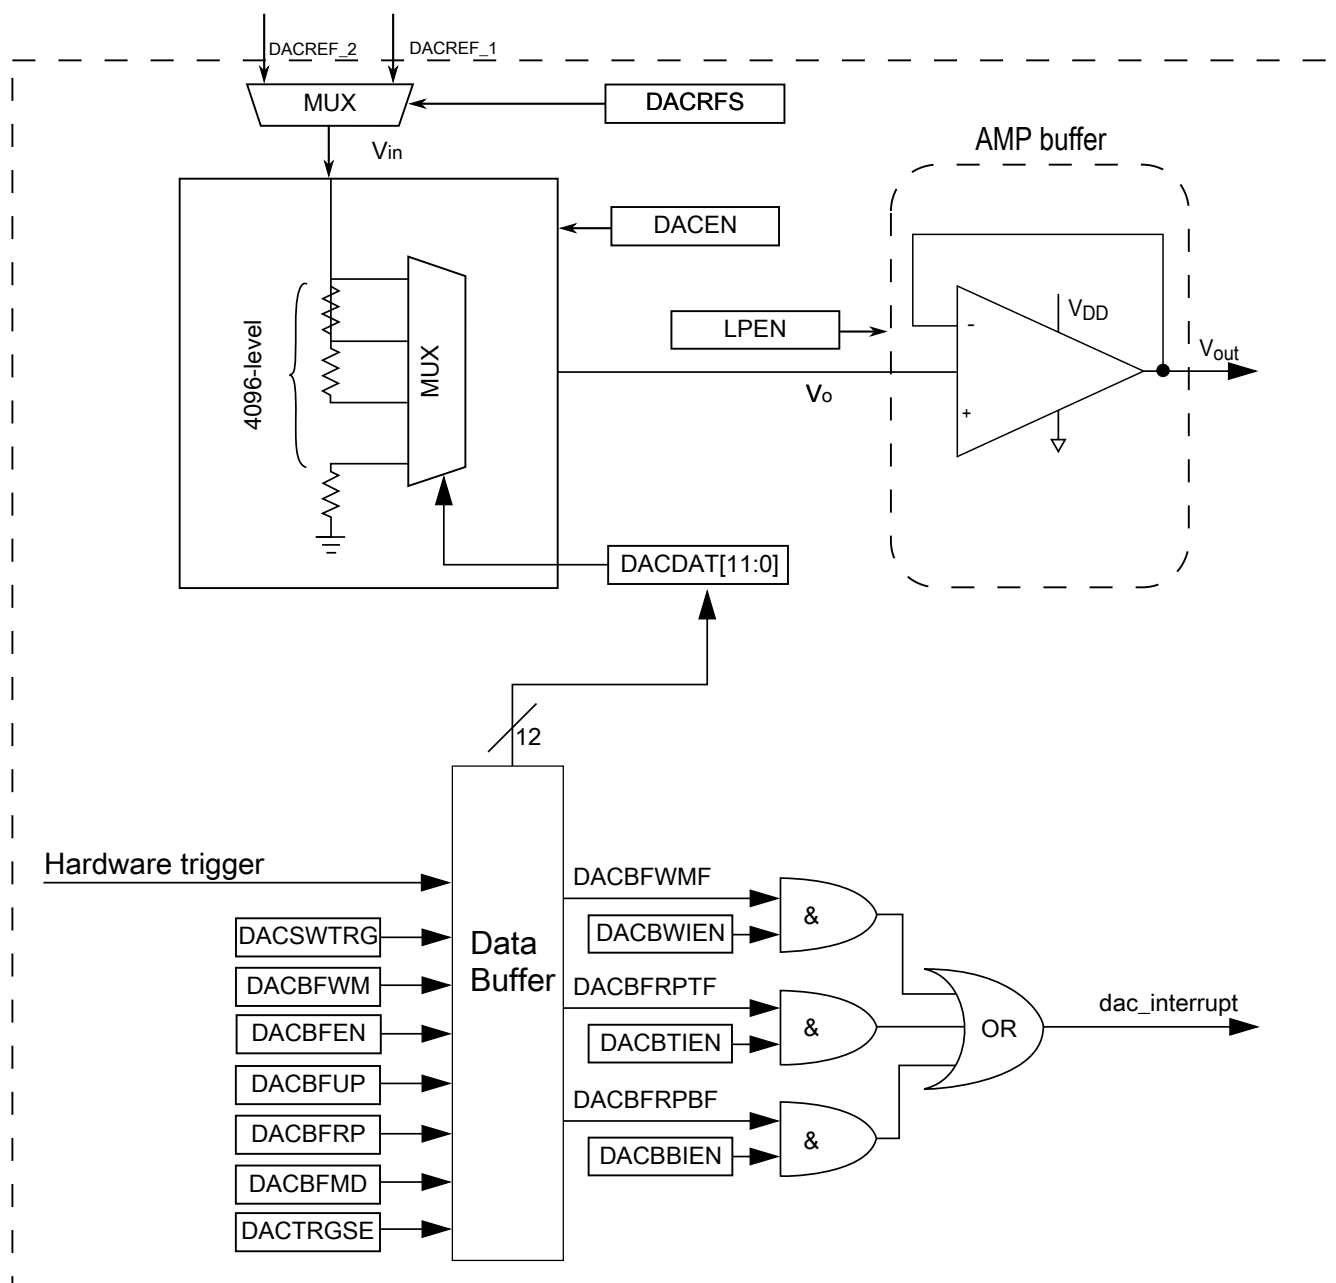

Figure 39-1. DAC block diagram

### 39.4 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

**DAC memory map**

| Absolute address (hex) | Register name                        | Width (in bits) | Access | Reset value | Section/page                |

### 39.4.1 DAC Data Low Register (DACx\_DATnL)

Address: Base address + 0h offset + (2d × i), where i=0d to 15d

|       |       |   |   |   |   |   |   |   |
|-------|-------|---|---|---|---|---|---|---|
| Bit   | 7     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | DATA0 |   |   |   |   |   |   |   |
| Write | DATA0 |   |   |   |   |   |   |   |
| Reset | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### DACx\_DATnL field descriptions

| Field        | Description  |
|--------------|--|
| 7-0<br>DATA0 | DATA0<br>When the DAC buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula: $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$<br>When the DAC buffer is enabled, DATA is mapped to the 16-word buffer. |

### 39.4.2 DAC Data High Register (DACx\_DATnH)

Address: Base address + 1h offset + (2d × i), where i=0d to 15d

|       |   |   |   |   |       |   |   |   |
|-------|---|---|---|---|-------|---|---|---|
| Bit   | 7 | 6 | 5 | 4 | 3     | 2 | 1 | 0 |
| Read  | 0 |   |   |   | DATA1 |   |   |   |
| Write | 0 |   |   |   | DATA1 |   |   |   |
| Reset | 0 | 0 | 0 | 0 | 0     | 0 | 0 | 0 |

#### DACx\_DATnH field descriptions

| Field           | Description  |
|-----------------|--|
| 7-4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3-0<br>DATA1    | DATA1<br>When the DAC Buffer is not enabled, DATA[11:0] controls the output voltage based on the following formula. $V_{out} = V_{in} * (1 + DACDAT0[11:0])/4096$<br>When the DAC buffer is enabled, DATA[11:0] is mapped to the 16-word buffer. |

### 39.4.3 DAC Status Register (DACx\_SR)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: Base address + 20h offset

|       |   |   |   |   |   |         |          |          |
|-------|---|---|---|---|---|---------|----------|----------|

| 0<br>DACBFEN    | <p>DAC Buffer Enable</p> <p>0 Buffer read pointer is disabled. The converted data is always the first word of the buffer.</p> <p>1 Buffer read pointer is enabled. The converted data is the word that the read pointer points to. It means converted data can be from any word of the buffer.</p>  |

## 39.4.6 DAC Control Register 2 (DACx\_C2)

Address: Base address + 23h offset

|       |         |   |   |   |         |   |   |   |
|-------|---------|---|---|---|---------|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3       | 2 | 1 | 0 |
| Read  | DACBFRP |   |   |   | DACBFUP |   |   |   |
| Write |         |   |   |   |         |   |   |   |
| Reset | 0       | 0 | 0 | 0 | 1       | 1 | 1 | 1 |

### DACx\_C2 field descriptions

| Field          | Description   |
|----------------|---|
| 7–4<br>DACBFRP | <p>DAC Buffer Read Pointer</p> <p>In normal mode it keeps the current value of the buffer read pointer. FIFO mode, it is the FIFO read pointer. It is writable in FIFO mode. User can configure it to same address to reset FIFO as empty.</p>  |
| 3–0<br>DACBFUP | <p>DAC Buffer Upper Limit</p> <p>In normal mode it selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it. In FIFO mode it is the FIFO write pointer. User cannot set Buffer Up limit in FIFO mode. In Normal mode its reset value is MAX. When IP is configured to FIFO mode, this register becomes Write_Pointer, and its value is initially set to equal READ_POINTER automatically, and the FIFO status is empty. It is writable and user can configure it to the same address to reset FIFO as empty.</p> |

## 39.5 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF\_1 and DACREF\_2 as the DAC reference voltage,  $V_{in}$  by C0 [DACRFS]. See the chip-specific DAC information to determine the source options for DACREF\_1 and DACREF\_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from  $V_{in}$  to  $V_{in}/4096$ , and the step is  $V_{in}/4096$ .

### 39.5.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to the analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever a hardware or software trigger event occurs.

The data buffer can be configured to operate in Normal mode, Swing mode, One-Time Scan mode or FIFO mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and C2[DACBFUP] by writing C2[DACBFRP].

### 39.5.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. SR[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, C2[DACBFRP] = C2[DACBFUP]. SR[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, SR[DACBFWMF] is set when the DAC buffer read pointer has reached the position defined by C1[DACBFWM]. C1[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from C2[DACBFUP].

### 39.5.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

**Table 39-118. Modes of DAC data buffer operation**

| Modes                     | Description  |
|---------------------------|--|
| Buffer Normal mode        | This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.   |
| Buffer Swing mode         | This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.  |
| Buffer One-time Scan mode | The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again.<br><br><b>NOTE:</b> If the software set the read pointer to the upper limit, the read pointer will not advance in this mode. |

*Table continues on the next page...*

**Table 39-118. Modes of DAC data buffer operation (continued)**

| Modes  | Description  |
|--|--|
| <p style="text-align: center;">FIFO Mode</p> | <p>In FIFO mode, the buffer is organized as a FIFO. For a valid write to any DACDATx, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32bit interface. For any 16bit or 8bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. For any 32bit FIFO access, the Write_Pointer needs to be an EVEN number; otherwise, the write is ignored.</p> <p><b>NOTE:</b> A successful 32bit FIFO write will increase the write pointer by 2. Any write will cause the FIFO over-flow will be ignored, the cases includes: 1.FIFO is full, the write will be ignored. 2.FIFO is nearly full (FIFO_SIZE-1), 32bit write will be ignored.</p> <p><b>NOTE:</b> For 8bit write, address bit[0] determine which byte lane will be written to the FIFO according to little endian alignment. Only both byte lanes are written will the write pointer increase. User need to make sure 8bit access happened in pair and both upper &amp; lower bytes are written. There is no requirement on which byte write first. In FIFO mode, there is no change to read access of DACDATx (from normal mode), read to DACDATx will return the DATA addressed by the access address to the data buffer, and both write pointer and read pointer in FIFO mode will NOT be changed by read access. FIFO write can be happened when DAC is not enabled for 1st data conversion enable. But FIFO mode need to work at buffer Enabled at DACC1[DACBFEN].</p> <p>In FIFO mode, the DATA BUF will be organized as FIFO.</p> |

### 39.5.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

### 39.5.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

### 39.5.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

**Table 39-119. Modes of operation**

| Modes of operation | Description  |
|--------------------|--|
| Wait mode          | The DAC will operate normally, if enabled.   |
| Stop mode          | <p>If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop.</p> <p>In low-power stop modes, the DAC is fully shut down.</p> |

**NOTE**

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

# Chapter 40

## Voltage Reference (VREFV1)

### 40.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The VREFV1 Voltage Reference is intended to supply an accurate voltage output that can be trimmed in 0.5 mV steps. The VREFV1 can be used in applications to provide a reference voltage to external devices or used internally as a reference to analog peripherals such as the ADC, DAC, or CMP. The voltage reference has two operating modes that provide different levels of supply rejection and power consumption.

The following figure is a block diagram of the Voltage Reference.

Figure 40-1. Voltage reference block diagram

### 40.1.1 Overview

The Voltage Reference provides a buffered reference voltage with high output current for use as an external reference. In addition, the buffered reference is available internally for use with on chip peripherals such as ADCs and DACs. Refer to the chip configuration chapter for a description of these options. The reference voltage is output on a dedicated output pin when the VREF is enabled. The Voltage Reference output can be trimmed with a resolution of 0.5mV by means of the TRM register TRIM[5:0] bitfield.

### 40.1.2 Features

The Voltage Reference has the following features:

- Programmable trim register with 0.5 mV steps, automatically loaded with factory trimmed value upon reset
- Programmable buffer mode selection:
  - Off

- Bandgap enabled/standby (output buffer disabled)
- High-power buffer mode (output buffer enabled)
- 1.2 V output at room temperature
- Dedicated output pin, VREF\_OUT
- Load regulation in high-power mode

### 40.1.3 Modes of Operation

The Voltage Reference continues normal operation in Run, Wait, and Stop modes. The Voltage Reference can also run in Very Low Power Run (VLPR), Very Low Power Wait (VLPW) and Very Low Power Stop (VLPS). The VREF regulator is not available in any Very Low Power modes and must be disabled (SC[REGEN]=0) before entering these modes. Note however that the accuracy of the output voltage will be reduced (by as much as several mVs) when the VREF regulator is not used.

#### NOTE

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

### 40.1.4 VREF Signal Descriptions

The following table shows the Voltage Reference signals properties.

**Table 40-1. VREF Signal Descriptions**

| Signal   | Description                                   | I/O |
|----------|---|-----|
| VREF_OUT | Internally-generated Voltage Reference output | O   |

#### NOTE

- In Disable mode, the status of the VREF\_OUT signal is high-impedance.

## 40.2 Memory Map and Register Definition

### VREF memory map

| Absolute address (hex) | Register name                              | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|--|-----------------|--------|-------------|-----------------------------|
| 4007_4000              | VREF Trim Register (VREF_TRM)              | 8               | R/W    | Undefined   | <a href="#">40.2.1/1062</a> |
| 4007_4001              | VREF Status and Control Register (VREF_SC) | 8               | R/W    | 00h         | <a href="#">40.2.2/1063</a> |

### 40.2.1 VREF Trim Register (VREF\_TRM)

This register contains bits that contain the trim data for the Voltage Reference.

Address: 4007\_4000h base + 0h offset = 4007\_4000h

| Bit   | 7        | 6  | 5    | 4  | 3  | 2  | 1  | 0  |
|-------|----------|----|------|----|----|----|----|----|
| Read  | Reserved | 0  | TRIM |    |    |    |    |    |
| Write |          |    |      |    |    |    |    |    |
| Reset | x*       | x* | x*   | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### VREF\_TRM field descriptions

| Field         | Description   |
|---------------|---|
| 7<br>Reserved | This field is reserved.<br>Upon reset this value is loaded with a factory trim value.<br>This bit must always be written with the original reset value.   |
| 6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 5–0<br>TRIM   | Trim bits<br>Upon reset this value is loaded with a factory trim value.<br>These bits change the resulting VREF by approximately $\pm 0.5$ mV for each step.<br><b>NOTE:</b> Min = minimum and max = maximum voltage reference output. For minimum and maximum voltage reference output values, refer to the Data Sheet for this chip.<br><br>000000 Min<br>.....<br>111111 Max |

## 40.2.2 VREF Status and Control Register (VREF\_SC)

This register contains the control bits used to enable the internal voltage reference and to select the VREF mode to be used.

Address: 4007\_4000h base + 1h offset = 4007\_4001h

| Bit   | 7      | 6     | 5        | 4 | 3 | 2      | 1       | 0 |
|-------|--------|-------|----------|---|---|--------|---------|---|
| Read  | VREFEN | REGEN | Reserved | 0 | 0 | VREFST | MODE_LV |   |
| Write |        |       |          |   |   |        |         |   |
| Reset | 0      | 0     | 0        | 0 | 0 | 0      | 0       | 0 |

### VREF\_SC field descriptions

| Field          | Description   |
|----------------|---|
| 7<br>VREFEN    | Internal Voltage Reference enable<br>This bit is used to enable the bandgap reference within the Voltage Reference module.<br><b>NOTE:</b> After the VREF is enabled, turning off the clock to the VREF module via the corresponding clock gate register will not disable the VREF. VREF must be disabled via this VREFEN bit.<br>0 The module is disabled.<br>1 The module is enabled. |
| 6<br>REGEN     | Regulator enable<br>This bit is used to enable the internal 1.75 V VREF regulator to produce a constant internal voltage supply in order to reduce the sensitivity to external supply noise and variation. The VREF regulator must not be enabled when entering VLPR, VLPW or VLPS modes.<br>0 Internal 1.75 V regulator is disabled.<br>1 Internal 1.75 V regulator is enabled.        |
| 5<br>Reserved  | This field is reserved.<br>This bit must always be written to zero.   |

### VREF\_SC field descriptions (continued)

| Field | Description               |
|-------|---------------------------|
| 01    | High-power buffer enabled |
| 10    | Reserved                  |
| 11    | Reserved                  |

## 40.3 Functional Description

The Voltage Reference is a bandgap buffer system. Unity gain amplifiers are used.

The VREF\_OUT signal is available as an internal reference when it is enabled. A 100 nF capacitor must be connected between VREF\_OUT and VSSA.

The following table shows all possible function configurations of the Voltage Reference.

**Table 40-5. Voltage Reference function configurations**

| SC[VREFEN] | SC[MODE_LV] | Configuration  | Functionality   |
|------------|-------------|--|---|
| 0          | X           | Voltage Reference disabled                                       | Off   |
| 1          | 00          | Voltage Reference enabled, only the VREF bandgap is on           | Startup and standby   |
| 1          | 01          | Voltage Reference enabled, VREF bandgap and high-power buffer on | VREF_OUT available for internal and external use. 100 nF capacitor is required. |
| 1          | 10          | Reserved   | Reserved  |
| 1          | 11          | Reserved   | Reserved  |

### 40.3.1 Voltage Reference Disabled, SC[VREFEN] = 0

When SC[VREFEN] = 0, the Voltage Reference is disabled, all bandgap and buffers are disabled. The Voltage Reference is in off mode.

### 40.3.2 Voltage Reference Enabled, SC[VREFEN] = 1

When SC[VREFEN] = 1, the Voltage Reference is enabled, and different modes can be set by the SC[MODE\_LV] bits.

### 40.3.2.1 SC[MODE\_LV]=00

The internal bandgap is enabled to generate an accurate 1.2 V output that can be trimmed with the TRM register's TRIM[5:0] bitfield. The bandgap requires some time for startup and stabilization. SC[VREFST] can be monitored to determine if the stabilization and startup is complete.

The output buffer is disabled in this mode, and there is no buffered voltage output. The Voltage Reference is in standby mode. If this mode is first selected and the high-power buffer mode is subsequently enabled, there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet.

### 40.3.2.2 SC[MODE\_LV] = 01

The high-power buffer is enabled to generate a buffered 1.2 V voltage to VREF\_OUT. If this mode is entered from the standby mode (SC[MODE\_LV] = 00, SC[VREFEN] = 1) there will be a delay before the buffer output is settled at the final value. This is the buffer start up delay (Tstup) and the value is specified in the appropriate device data sheet. If this mode is entered when the VREF module is enabled then you must wait the longer of Tstup or until SC[VREFST] = 1.

### 40.3.2.3 SC[MODE\_LV] = 10

Reserved

### 40.3.2.4 SC[MODE\_LV] = 11

Reserved

## 40.4 Initialization/Application Information

The Voltage Reference requires some time for startup and stabilization. After SC[VREFEN] = 1, SC[VREFST] can be monitored to determine if the stabilization and startup of the VREF bandgap is complete.

When the Voltage Reference is already enabled and stabilized, changing SC[MODE\_LV] will not clear SC[VREFST] but there will be some startup time before the output voltage at the VREF\_OUT pin has settled. This is the buffer start up delay ( $T_{\text{stup}}$ ) and the value is specified in the appropriate device data sheet. Also, there will be some settling time when a step change of the load current is applied to the VREF\_OUT pin.

When the 1.75V VREF regulator is disabled, the VREF\_OUT voltage will be more sensitive to supply voltage variation. It is recommended to use this regulator to achieve optimum VREF\_OUT performance.

# Chapter 41

## Programmable Delay Block (PDB)

### 41.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved. The PDB can optionally provide pulse outputs (Pulse-Out's) that are used as the sample window in the CMP block.

#### 41.1.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to 8 configurable PDB channels for ADC hardware trigger
  - One PDB channel is associated with one ADC
  - One trigger output for ADC hardware trigger and up to 8 pre-trigger outputs for ADC trigger select per PDB channel
  - Trigger outputs can be enabled or disabled independently
  - One 16-bit delay register per pre-trigger output
  - Optional bypass of the delay registers of the pre-trigger outputs
  - Operation in One-Shot or Continuous modes

- Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel
- One programmable delay interrupt
- One sequence error interrupt
- One channel flag and one sequence error flag per pre-trigger
- DMA support
- Up to 8 DAC interval triggers
  - One interval trigger output per DAC
  - One 16-bit delay interval register per DAC trigger output
  - Optional bypass of the delay interval trigger registers
  - Optional external triggers
- Up to 8 pulse outputs (pulse-out's)
  - Pulse-out's can be enabled or disabled independently
  - Programmable pulse width

### NOTE

The number of PDB input and output triggers are chip-specific. See the chip-specific PDB information for details.

## 41.1.2 Implementation

In this section, the following letters refer to the number of output triggers:

- $N$ —Total available number of PDB channels.
- $n$ —PDB channel number, valid from 0 to  $N-1$ .
- $M$ —Total available pre-trigger per PDB channel.
- $m$ —Pre-trigger number, valid from 0 to  $M-1$ .
- $X$ —Total number of DAC interval triggers.
- $x$ —DAC interval trigger output number, valid from 0 to  $X-1$ .

- Y—Total number of Pulse-Out's.
- y—Pulse-Out number, valid value is from 0 to Y-1.

### NOTE

The number of module output triggers to core is chip-specific. For module to core output triggers implementation, see the chip configuration information.

#### 41.1.3 Back-to-back acknowledgment connections

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

#### 41.1.4 DAC External Trigger Input Connections

The implementation of DAC external trigger inputs is chip-specific. See the chip configuration information for details.

#### 41.1.5 Block diagram

This diagram illustrates the major components of the PDB.

**Figure 41-1. PDB block diagram**

In this diagram, only one PDB channel *n*, one DAC interval trigger *x*, and one Pulse-Out *y* are shown. The PDB-enabled control logic and the sequence error interrupt logic are not shown.

### 41.1.6 Modes of operation

PDB ADC trigger operates in the following modes:

- Disabled—Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.
- Debug—Counter is paused when processor is in Debug mode, and the counter for the DAC trigger is also paused in Debug mode.
- Enabled One-Shot—Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.
- Enabled Continuous—Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.
- Enabled Bypassed—The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

## 41.2 PDB signal descriptions

This table shows the detailed description of the external signal.

**Table 41-1. PDB signal descriptions**

| Signal | Description  | I/O |
|--------|--|-----|
| EXTRG  | External Trigger Input Source<br><br>If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter. | I   |

## 41.3 Memory map and register definition

### PDB memory map

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value | Section/page                 |

## 41.4 Functional description

### 41.4.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared to several different digital values. If the PDB is enabled, then a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on a selected trigger input source, or if a software trigger is selected and SC[SWTRIG] is written with 1. For each channel, a delay *m* determines the time between assertion of the trigger input event to the time at which changes in the pre-trigger *m* output signal are started. The time is defined as:

- Trigger input event to pre-trigger  $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$  peripheral clock cycles
- Add 1 additional peripheral clock cycle to determine the time when the channel trigger output changes.

Each channel is associated with 1 ADC block. PDB channel  $n$  pre-trigger outputs 0 to  $M$ ; each pre-trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block before the actual trigger occurs. When the ADC receives the rising edge of the trigger, the ADC will start the conversion according to the precondition determined by the pre-triggers. The ADC contains  $M$  sets of configuration and result registers, allowing it to alternate conversions between  $M$  different analog sources (like a ping-pong game). The pre-trigger outputs are used to specify which signal will be sampled next. When a pre-trigger  $m$  is asserted, the ADC conversion is triggered with set  $m$  of the configuration and result registers.

The waveforms shown in the following diagram show the pre-trigger and trigger outputs of PDB channel  $n$ . The delays can be independently set using the  $CHnDLYm$  registers, and the pre-triggers can be enabled or disabled in  $CHnC1[EN[m]]$ .

**Figure 41-74. Pre-trigger and trigger outputs**

The delay in  $CHnDLYm$  register can be optionally bypassed, if  $CHnC1[TOS[m]]$  is cleared. In this case, when the trigger input event occurs, the pre-trigger  $m$  is asserted after 2 peripheral clock cycles.

The PDB can be configured for back-to-back operation. Back-to-back operation enables the ADC conversion completions to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back operation is enabled by setting  $CHnC1[BB[m]]$ , then the delay  $m$  is ignored and the pre-trigger  $m$  is asserted 2 peripheral cycles after the acknowledgment  $m$  is received. The acknowledgment connections in this MCU are described in [Back-to-back acknowledgment connections](#).

When a pre-trigger from a PDB channel  $n$  is asserted, the associated lock of the pre-trigger becomes active. The associated lock is released by the rising edge of the corresponding  $ADCnSC1[COCO]$ ; the  $ADCnSC1[COCO]$  should be cleared after the conversion result is read, so that the next rising edge of  $ADCnSC1[COCO]$  can be generated to clear the lock later. The lock becomes inactive when:

- the rising edge of corresponding  $ADCnSC1[COCO]$  occurs,

- or the corresponding PDB pre-trigger is disabled,
- or the PDB is disabled

The channel  $n$  trigger output is suppressed when any of the locks of the pre-triggers in channel  $n$  is active. If a new pre-trigger  $m$  asserts when there is active lock in the PDB channel  $n$ , then a register flag bit  $CHnS[ERR[m]]$  (associated with the pre-trigger  $m$ ) is set. If  $SC[PDBEIE]$  is set, then the sequence error interrupt is generated. A sequence error typically happens because the delay  $m$  is set too short and the pre-trigger  $m$  asserts before the previously triggered ADC conversion finishes.

When the PDB counter reaches the value set in  $IDLY$  register, the  $SC[PDBIF]$  flag is set. A PDB interrupt can be generated if  $SC[PDBIE]$  is set and  $SC[DMAEN]$  is cleared. If  $SC[DMAEN]$  is set, then the PDB requests a DMA transfer when the  $SC[PDBIF]$  flag is set.

The modulus value in the  $MOD$  register is used to reset the counter back to zero at the end of the count. If  $SC[CONT]$  is set, then the counter will then resume a new count; otherwise, the counter operation will stop until the next trigger input event occurs.

## 41.4.2 PDB trigger input source selection

The PDB has up to 15 trigger input sources, namely Trigger-In 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through  $SC[SWTRIG]$ .  $SC[TRIGSEL]$  selects the active trigger input source or software trigger.

For the trigger input sources implemented in this MCU, see chip configuration information.

## 41.4.3 DAC interval trigger outputs

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter  $x$  is reset and started when a trigger input event occurs if  $DACINTCx[EXT]$  is cleared. When the interval counter  $x$  is equal to the value set in  $DACINTx$  register, the DAC interval trigger  $x$  output generates a pulse of one peripheral clock cycle width to update the  $DACx$ . If  $DACINTCx[EXT]$  is set, the DAC interval counter is bypassed and the interval trigger output  $x$  generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the  $DACINTCx[TOE]$ .

DAC interval counters are also reset when the PDB counter reaches the  $MOD$  register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

The DAC interval trigger pulse and the ADC pre-trigger/trigger pulses together allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

**Figure 41-75. PDB ADC triggers and DAC interval triggers use case**

**NOTE**

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

### 41.4.4 Pulse-Out's

PDB can generate pulse outputs of configurable width. When PDB counter reaches the value set in PO<sub>y</sub>DLY[DLY1], the Pulse-Out goes high; when the counter reaches PO<sub>y</sub>DLY[DLY2], it goes low. PO<sub>y</sub>DLY[DLY2] can be set either greater or less than PO<sub>y</sub>DLY[DLY1].

ADC pre-trigger/trigger outputs and Pulse-Out generation have the same time base, because they both share the PDB counter.

The pulse-out connections implemented in this MCU are described in the device's chip configuration details.

## 41.4.5 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)
- PDB Interrupt Delay register (IDLY)
- PDB Channel  $n$  Delay  $m$  register (CH $n$ DLY $m$ )
- DAC Interval  $x$  register (DACINT $x$ )
- PDB Pulse-Out  $y$  Delay register (PO $y$ DLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized as shown in the table below.

**Table 41-76. Circumstances of update to the delay registers**

| SC[LDMOD] | Update to the delay registers  |
|-----------|--|
| 00        | The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].             |
| 01        | The PDB counter reaches the MOD register value after 1 is written to SC[LDOK].   |
| 10        | A trigger input event is detected after 1 is written to SC[LDOK].  |
| 11        | Either the PDB counter reaches the MOD register value, or a trigger input event is detected, after 1 is written to SC[LDOK]. |

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

**Figure 41-76. Registers update with SC[LDMOD] = 00**

**Figure 41-77. Registers update with SC[LDMOD] = x1**

### 41.4.6 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

**Table 41-77. PDB interrupt summary**

| Interrupt                    | Flags      | Enable bit                      |
|------------------------------|------------|---------------------------------|
| PDB Interrupt                | SC[PDBIF]  | SC[PDBIE] = 1 and SC[DMAEN] = 0 |
| PDB Sequence Error Interrupt | CHnS[ERRm] | SC[PDBEIE] = 1                  |

### 41.4.7 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

## 41.5 Application information

### 41.5.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

# Chapter 42

## FlexTimer Module (FTM)

### 42.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

#### 42.1.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the HCS08 Timer PWM Module – TPM, used for many years on Freescale's 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Fault control inputs
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, fault control, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

## 42.1.2 Features

The FTM features include:

- FTM source clock is selectable
  - Source clock can be the system clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter
  - It can be a free-running counter or a counter with initial and final value
  - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:

- The capture can occur on rising edges, falling edges or both edges
- An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

### 42.1.3 Modes of operation

When the MCU is in an active BDM mode, the FTM temporarily suspends all counting until the MCU returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a

real time reference or provide the interrupt sources needed to wake the MCU from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

#### 42.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CH<sub>n</sub> (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

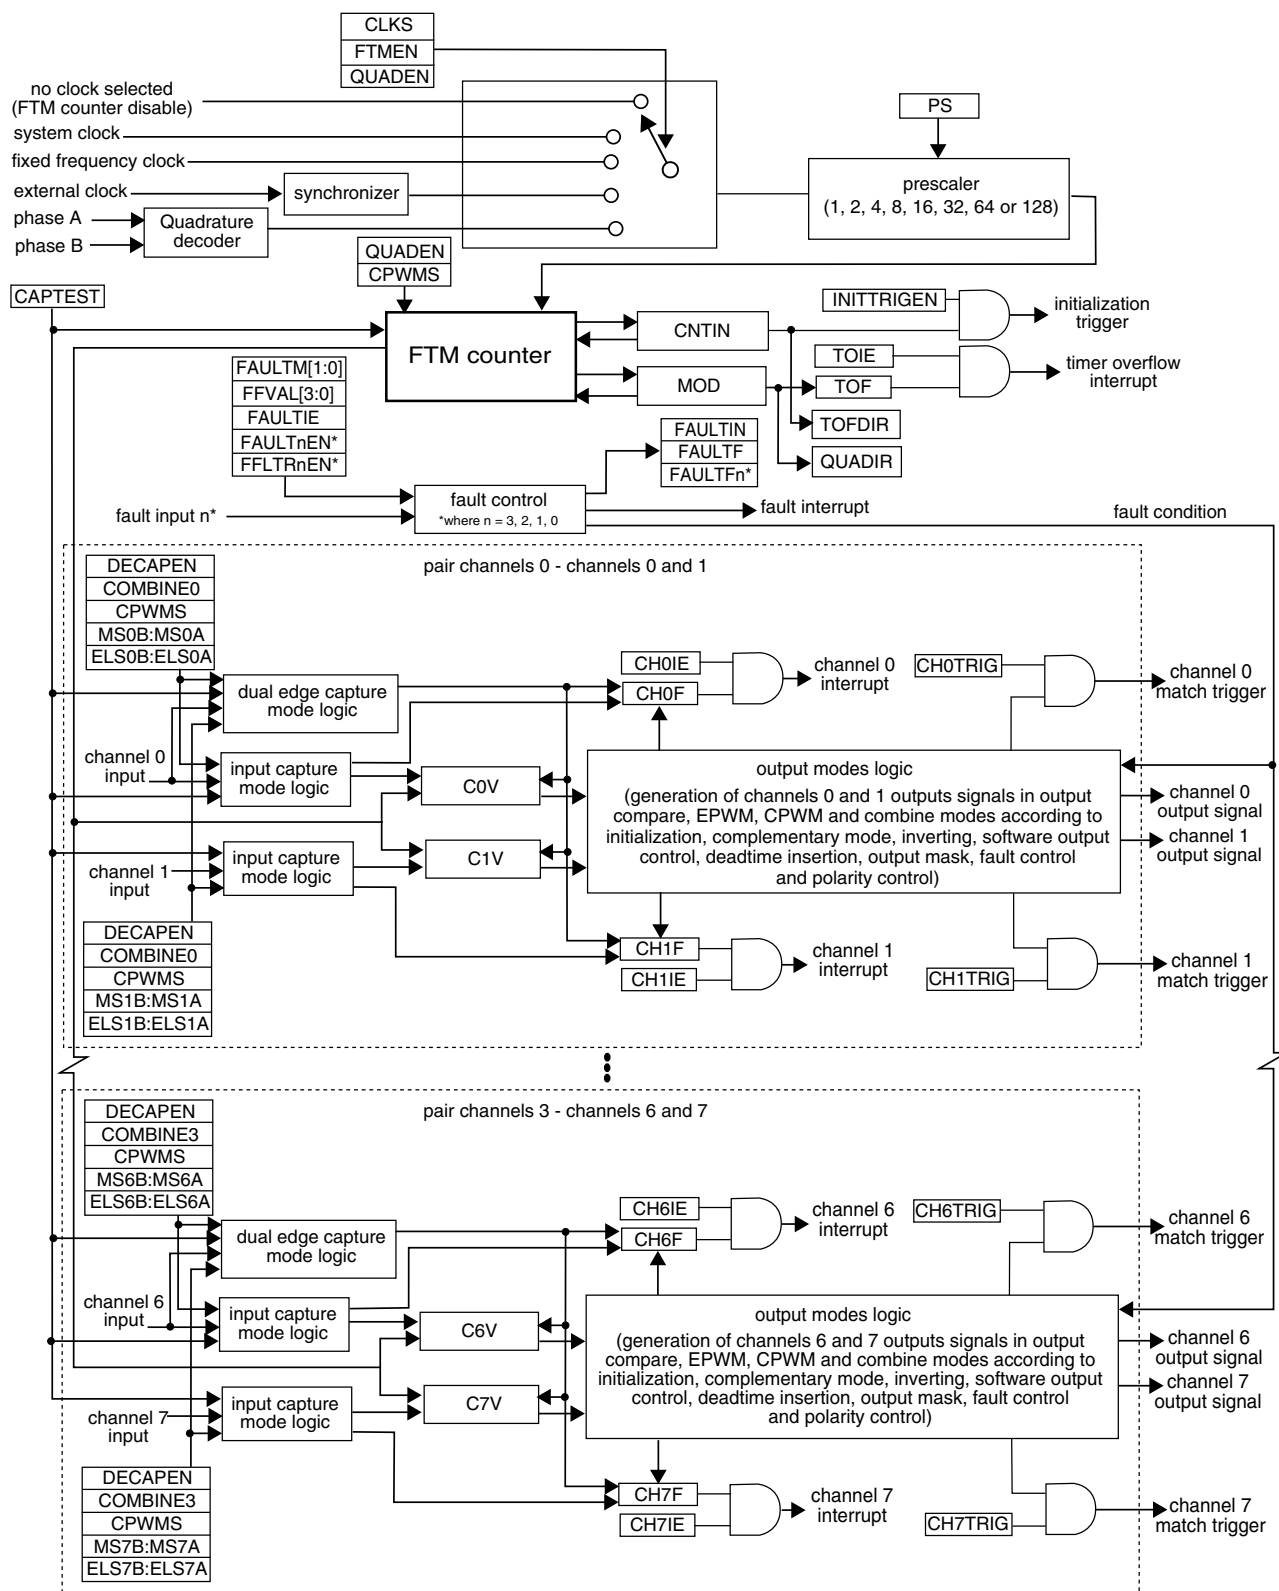

Figure 42-1. FTM block diagram

## 42.2 FTM signal descriptions

Table 42-1 shows the user-accessible signals for the FTM.

**Table 42-1. FTM signal descriptions**

| Signal | Description   | I/O | Function  |
|--------|---|-----|---|
| EXTCLK | External clock. FTM external clock can be selected to drive the FTM counter.            | I   | The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.  |
| CHn    | FTM channel (n), where n can be 7-0   | I/O | Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.  |
| FAULTj | Fault input (j), where j can be 3-0   | I   | The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTJEN bit in the FLTCTRL register. |
| PHA    | Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A. | I   | The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .  |
| PHB    | Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B. | I   | The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .  |

## 42.3 Memory map and register definition

### 42.3.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

### Note

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

## 42.3.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

FTM memory map

| Absolute address (hex) | Register name                                    | Width (in bits) | Access | Reset value | Section/page                 |

### 42.3.3 Status And Control (FTMx\_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset

**FTMx\_SC field descriptions**

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7<br>TOF         | <p>Timer Overflow Flag</p> <p>Set by hardware when the FTM counter passes the value in the MOD register. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect.</p> <p>If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF.</p> <p>0 FTM counter has not overflowed.<br/>1 FTM counter has overflowed.</p> |

Table continues on the next page...

### FTMx\_SC field descriptions (continued)

| Field       | Description   |
|-------------|---|
| 6<br>TOIE   | <p>Timer Overflow Interrupt Enable</p> <p>Enables FTM overflow interrupts.</p> <p>0 Disable TOF interrupts. Use software polling.<br/>1 Enable TOF interrupts. An interrupt is generated when TOF equals one.</p>   |

| 2–0<br>PS   | <p>Prescale Factor Selection</p> <p>Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>000 Divide by 1<br/>001 Divide by 2<br/>010 Divide by 4<br/>011 Divide by 8<br/>100 Divide by 16<br/>101 Divide by 32<br/>110 Divide by 64<br/>111 Divide by 128</p> |

#### 42.3.4 Counter (FTMx\_CNT)

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

Address: Base address + 4h offset

**FTMx\_CNT field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Counter Value   |

**42.3.5 Modulo (FTMx\_MOD)**

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

**FTMx\_MOD field descriptions**

| Field             | Description             |
|-------------------|-------------------------|
| 31–16<br>Reserved | This field is reserved. |
| 15–0<br>MOD       | Modulo Value            |

### 42.3.6 Channel (n) Status And Control (FTMx\_CnSC)

CnSC contains the channel-interrupt-status flag and control bits used to configure the interrupt enable, channel configuration, and pin function.

**Table 42-67. Mode, edge, and level selection**

| DECAPEN | COMBINE | CPWMS | MSnB:MSnA | ELSnB:ELSnA      | Mode   | Configuration                            |                        |   |   |

**42.3.7 Channel (n) Value (FTMx\_CnV)**

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

**FTMx\_CnV field descriptions**

| Field             | Description  |
|-------------------|--|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                |
| 15–0<br>VAL       | Channel Value<br>Captured FTM counter value of the input modes or the match value for the output modes |

**42.3.8 Counter Initial Value (FTMx\_CNTIN)**

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Address: Base address + 4Ch offset

**FTMx\_CNTIN field descriptions**

| Field             | Description                      |
|-------------------|----------------------------------|
| 31–16<br>Reserved | This field is reserved.          |
| 15–0<br>INIT      | Initial Value Of The FTM Counter |

**42.3.9 Capture And Compare Status (FTMx\_STATUS)**

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

**memory map and register definition**

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

Address: Base address + 50h offset

**FTMx\_STATUS field descriptions**

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

### 42.3.10 Features Mode Selection (FTMx\_MODE)

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization

memory map and register definition

- Write protection
- Channel output initialization

These controls relate to all channels within this module.

| Field      | Description  |
|------------|--|
|            | <p>Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See <a href="#">PWM synchronization</a>. The PWMSYNC bit configures the synchronization when SYNCMODE is 0.</p> <p>0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization.</p> <p>1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.</p> |
| 2<br>WPDIS | <p>Write Protection Disable</p> <p>When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect.</p> <p>0 Write protection is enabled.</p> <p>1 Write protection is disabled.</p>   |
| 1<br>INIT  | <p>Initialize The Channels Output</p> <p>When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect.</p> <p>The INIT bit is always read as 0.</p>   |
| 0<br>FTMEN | <p>FTM Enable</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 TPM compatibility. Free running counter and synchronization compatible with TPM.</p> <p>1 Free running counter and synchronization are different from TPM behavior.</p>  |

#### 42.3.11 Synchronization (FTMx\_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

#### NOTE

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

**42.3.13 Output Mask (FTMx\_OUTMASK)**

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

### FTMx\_COMBINE field descriptions (continued)

| Field         | Description  |
|---------------|--|
| 0<br>COMBINE0 | <p>Combine Channels For <math>n = 0</math></p> <p>Enables the combine feature for channels (n) and (n+1).</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p> <p>0 Channels (n) and (n+1) are independent.<br/>           1 Channels (n) and (n+1) are combined.</p> |

### 42.3.15 Deadtime Insertion Control (FTMx\_DEADTIME)

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

### FTMx\_DEADTIME field descriptions

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>   |
| 7–6<br>DTPS      | <p>Deadtime Prescaler Value</p> <p>Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter.</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p> <p>0x Divide the system clock by 1.<br/>           10 Divide the system clock by 4.<br/>           11 Divide the system clock by 16.</p>   |
| 5–0<br>DTVAL     | <p>Deadtime Value</p> <p>Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS.</p> <p>Deadtime insert value = <math>(DTPS \times DTVAL)</math>.</p> <p>DTVAL selects the number of deadtime counts inserted as follows:</p> <p>When DTVAL is 0, no counts are inserted.<br/>           When DTVAL is 1, 1 count is inserted.<br/>           When DTVAL is 2, 2 counts are inserted.</p> <p>This pattern continues up to a possible 63 counts.</p> <p>This field is write protected. It can be written only when <math>MODE[WPDIS] = 1</math>.</p> |

### 42.3.16 FTM External Trigger (FTMx\_EXTTRIG)

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period.

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset

### FTMx\_EXTTRIG field descriptions

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.  |
| 7<br>TRIGF       | <p>Channel Trigger Flag</p> <p>Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect.</p> <p>If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF.</p> <p>0 No channel trigger was generated.<br/>1 A channel trigger was generated.</p> |
| 6<br>INITTRIGEN  | <p>Initialization Trigger Enable</p> <p>Enables the generation of the trigger when the FTM counter is equal to the CNTIN register.</p> <p>0 The generation of initialization trigger is disabled.<br/>1 The generation of initialization trigger is enabled.</p>   |
| 5<br>CH1TRIG     | <p>Channel 1 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled.<br/>1 The generation of the channel trigger is enabled.</p>  |
| 4<br>CH0TRIG     | <p>Channel 0 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled.<br/>1 The generation of the channel trigger is enabled.</p>  |
| 3<br>CH5TRIG     | <p>Channel 5 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled.<br/>1 The generation of the channel trigger is enabled.</p>  |
| 2<br>CH4TRIG     | <p>Channel 4 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled.<br/>1 The generation of the channel trigger is enabled.</p>  |
| 1<br>CH3TRIG     | <p>Channel 3 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p> <p>0 The generation of the channel trigger is disabled.<br/>1 The generation of the channel trigger is enabled.</p>  |
| 0<br>CH2TRIG     | <p>Channel 2 Trigger Enable</p> <p>Enables the generation of the channel trigger when the FTM counter is equal to the CnV register.</p>  |

*Table continues on the next page...*

### FTMx\_EXTTRIG field descriptions (continued)

| Field | Description  |
|-------|--|
| 0     | The generation of the channel trigger is disabled. |
| 1     | The generation of the channel trigger is enabled.  |

### 42.3.17 Channels Polarity (FTMx\_POL)

This register defines the output polarity of the FTM channels.

#### NOTE

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

| 0<br>POL0 | Channel 0 Polarity<br>Defines the polarity of the channel output.<br>This field is write protected. It can be written only when MODE[WPDIS] = 1.<br>0 The channel polarity is active high.<br>1 The channel polarity is active low. |

### 42.3.18 Fault Mode Status (FTMx\_FMS)

This register contains the fault detection flags, write protection enable bit, and the logic OR of the enabled fault inputs.

Address: Base address + 74h offset

**FTMx\_FMS field descriptions**

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7<br>FAULTF      | <p>Fault Detection Flag</p> <p>Represents the logic OR of the individual FAULTFj bits where j = 3, 2, 1, 0. Clear FAULTF by reading the FMS register while FAULTF is set and then writing a 0 to FAULTF while there is no existing fault condition at the enabled fault inputs. Writing a 1 to FAULTF has no effect.</p> <p>If another fault condition is detected in an enabled fault input before the clearing sequence is completed, the sequence is reset so FAULTF remains set after the clearing sequence is completed for the earlier fault condition. FAULTF is also cleared when FAULTFj bits are cleared individually.</p> <p>0 No fault condition was detected.<br/>1 A fault condition was detected.</p> |

### FTMx\_FMS field descriptions (continued)

| Field        | Description  |
|--------------|--|
|              | <p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF1 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input.<br/>1 A fault condition was detected at the fault input.</p>   |
| 0<br>FAULTF0 | <p>Fault Detection Flag 0</p> <p>Set by hardware when fault control is enabled, the corresponding fault input is enabled and a fault condition is detected at the fault input.</p> <p>Clear FAULTF0 by reading the FMS register while FAULTF0 is set and then writing a 0 to FAULTF0 while there is no existing fault condition at the corresponding fault input. Writing a 1 to FAULTF0 has no effect. FAULTF0 bit is also cleared when FAULTF bit is cleared.</p> <p>If another fault condition is detected at the corresponding fault input before the clearing sequence is completed, the sequence is reset so FAULTF0 remains set after the clearing sequence is completed for the earlier fault condition.</p> <p>0 No fault condition was detected at the fault input.<br/>1 A fault condition was detected at the fault input.</p> |

### 42.3.19 Input Capture Filter Control (FTMx\_FILTER)

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

#### NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Address: Base address + 78h offset

### 42.3.21 Quadrature Decoder Control And Status (FTMx\_QDCTRL)

This register has the control and status bits for the Quadrature Decoder mode.

Address: Base address + 80h offset

**FTMx\_QDCTRL field descriptions**

| Field            | Description  |
|------------------|--|
| 31–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7<br>PHAFLTREN   | Phase A Input Filter Enable<br><br>Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero.<br><br>0 Phase A input filter is disabled.<br>1 Phase A input filter is enabled.   |
| 6<br>PHBFLTREN   | Phase B Input Filter Enable<br><br>Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero.<br><br>0 Phase B input filter is disabled.<br>1 Phase B input filter is enabled.   |
| 5<br>PHAPOL      | Phase A Input Polarity<br><br>Selects the polarity for the quadrature decoder phase A input.<br><br>0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal.<br>1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.   |
| 4<br>PHBPOL      | Phase B Input Polarity<br><br>Selects the polarity for the quadrature decoder phase B input.<br><br>0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal.<br>1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.   |
| 3<br>QUADMODE    | Quadrature Decoder Mode<br><br>Selects the encoding mode used in the Quadrature Decoder mode.<br><br>0 Phase A and phase B encoding mode.<br>1 Count and direction encoding mode.  |
| 2<br>QUADIR      | FTM Counter Direction In Quadrature Decoder Mode<br><br>Indicates the counting direction.<br><br>0 Counting direction is decreasing (FTM counter decrement).<br>1 Counting direction is increasing (FTM counter increment).  |
| 1<br>TOFDIR      | Timer Overflow Direction In Quadrature Decoder Mode<br><br>Indicates if the TOF bit was set on the top or the bottom of counting.<br><br>0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register).<br>1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register). |

*Table continues on the next page...*

### FTMx\_QDCTRL field descriptions (continued)

| Field       | Description  |
|-------------|--|
| 0<br>QUADEN | <p>Quadrature Decoder Mode Enable</p> <p>Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See <a href="#">Table 42-7</a>.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Quadrature Decoder mode is disabled.<br/>1 Quadrature Decoder mode is enabled.</p> |

### 42.3.22 Configuration (FTMx\_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

|       |          |    |    |    |          |          |          |          |          |          |    |    |    |    |    |    |

### 42.3.24 Synchronization Configuration (FTMx\_SYNCONF)

This register selects the PWM synchronization configuration, SWOCTRL, INVCTRL and CNTIN registers synchronization, if FTM clears the TRIGj bit, where j = 0, 1, 2, when the hardware trigger j is detected.

Address: Base address + 8Ch offset

**FTMx\_SYNCONF field descriptions (continued)**

| Field | Description  |
|-------|--|
| 0     | FTM clears the TRIG <sub>j</sub> bit when the hardware trigger j is detected, where j = 0, 1, 2.         |
| 1     | FTM does not clear the TRIG <sub>j</sub> bit when the hardware trigger j is detected, where j = 0, 1, 2. |

**42.3.25 FTM Inverting Control (FTMx\_INVCTRL)**

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INV<sub>m</sub>EN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INV<sub>m</sub>EN bit is updated by the INVCTRL register synchronization.

Address: Base address + 90h offset

### 42.3.26 FTM Software Output Control (FTMx\_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

Address: Base address + 94h offset

### 42.3.27 FTM PWM Load (FTMx\_PWMLOAD)

Enables the loading of the MOD, CNTIN, C(n)V, and C(n+1)V registers with the values of their write buffers when the FTM counter changes from the MOD register value to its next value or when a channel (j) match occurs. A match occurs for the channel (j) when FTM counter = C(j)V.

## 42.4 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

## functional description

FTM counting is up.  
Channel (n) is in high-true EPWM mode.

PS[2:0] = 001  
CNTIN = 0x0000  
MOD = 0x0004  
CnV = 0x0002

**Figure 42-207. Notation used**

## 42.4.1 Clock source

The FTM has only one clock domain: the system clock.

### 42.4.1.1 Counter clock source

The CLKS[1:0] bits in the SC register select one of three possible clock sources for the FTM counter or disable the FTM counter. After any MCU reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration. Refer to the chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to assure that counter transitions are properly aligned to system clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

### 42.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

**Figure 42-208. Example of the prescaler counter**

### 42.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder mode](#)

#### 42.4.3.1 Up counting

Up counting is selected when:

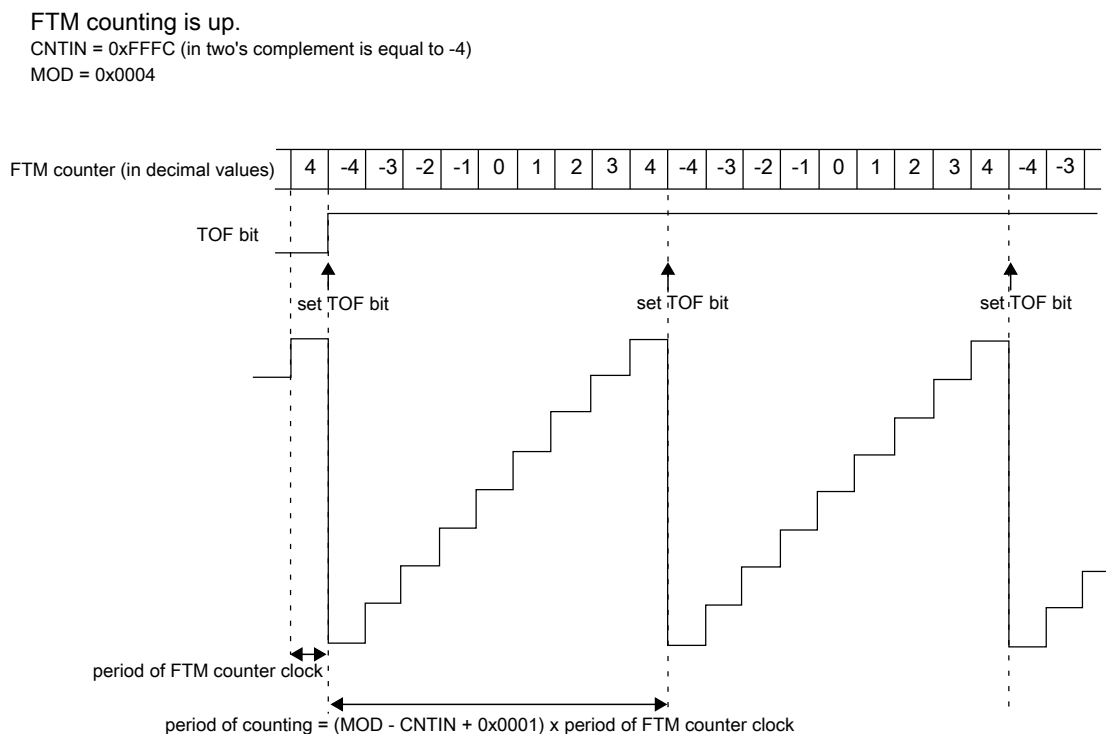

- QUADEN = 0, and
- CPWMS = 0

## functional description

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is  $(MOD - CNTIN + 0x0001) \times$  period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

**Figure 42-209. Example of FTM up and signed counting**

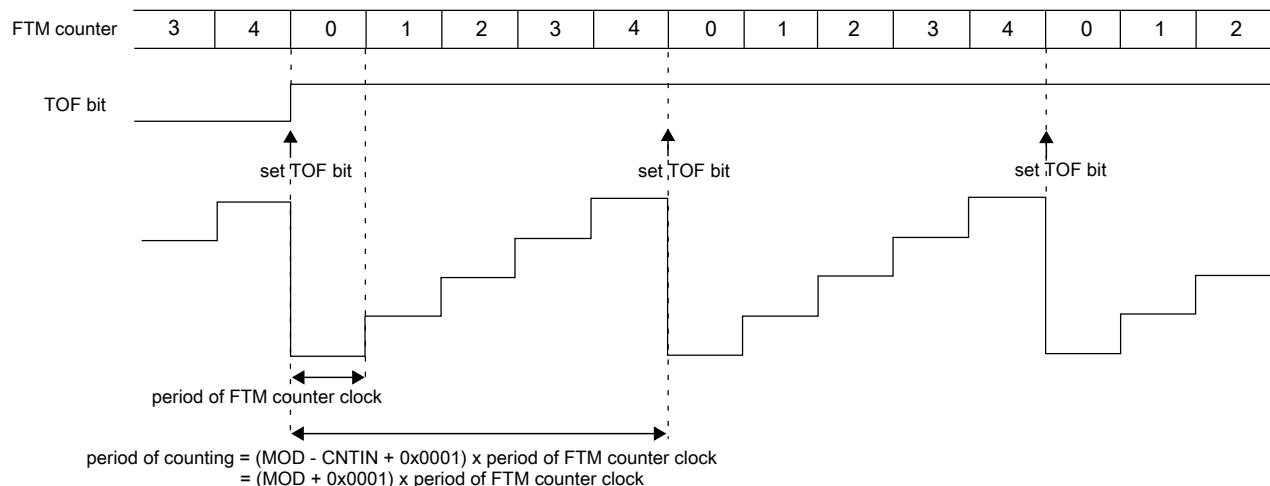

**Table 42-302. FTM counting based on CNTIN value**

| When                                  | Then   |
|---------------------------------------|--|
| CNTIN = 0x0000                        | The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.      |
| CNTIN[15] = 1                         | The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed. |
| CNTIN[15] = 0 and CNTIN $\neq$ 0x0000 | The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.                   |

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

**Figure 42-210. Example of FTM up counting with CNTIN = 0x0000**

### Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

## functional description

**Figure 42-211. Example of up counting when the value of CNTIN is greater than the value of MOD**

### 42.4.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (\text{MOD} - \text{CNTIN}) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

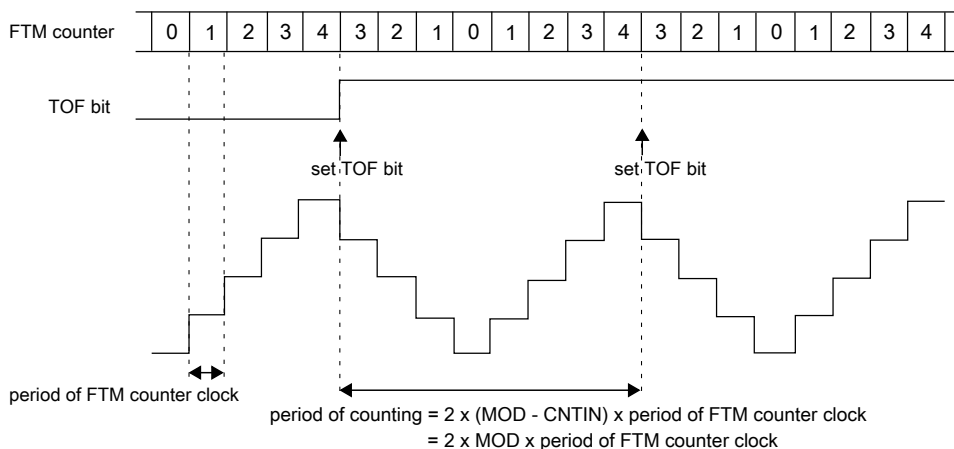

Figure 42-212. Example of up-down counting when CNTIN = 0x0000

**Note**

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if  $C_nV > \text{CNTIN}$ , or
- if  $C_nV = 0$  or if  $C_nV[15] = 1$ . In this case, 0% CPWM is generated.

**42.4.3.3 Free running counter**

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

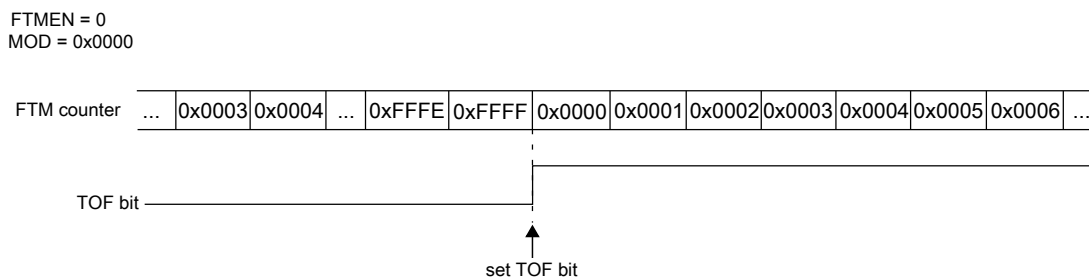

Figure 42-213. Example when the FTM counter is free running

The FTM counter is also a free running counter when:

functional description

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

### 42.4.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).

### 42.4.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

Figure 42-214. Periodic TOF when NUMTOF = 0x02

Figure 42-215. Periodic TOF when NUMTOF = 0x00

#### 42.4.4 Input Capture mode

The Input Capture mode is selected when:

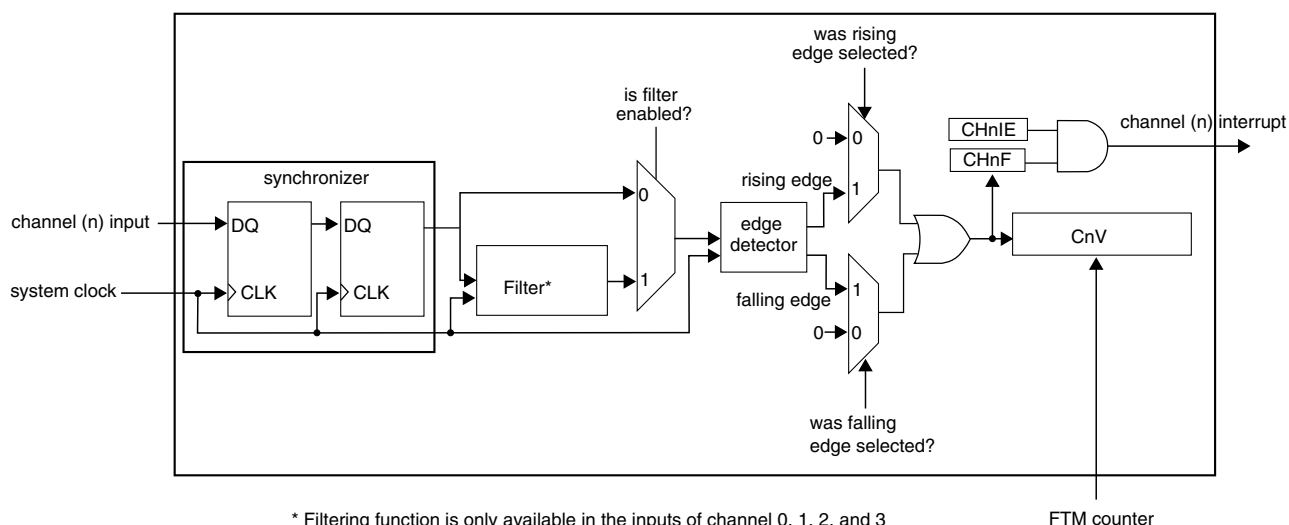

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0
- MSnB:MSnA = 0:0, and
- ELSnB:ELSnA  $\neq$  0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

\* Filtering function is only available in the inputs of channel 0, 1, 2, and 3

FTM counter

**Figure 42-216. Input Capture mode**

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

### 42.4.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

**Figure 42-217. Channel input filter**

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by  $CHnFVAL[3:0]$  ( $\times 4$  system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when  $CHnFVAL[3:0]$  bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If ( $CHnFVAL[3:0] \neq 0000$ ), then the input signal is delayed by the minimum pulse width ( $CHnFVAL[3:0] \times 4$  system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words,  $CHnF$  is set  $(4 + 4 \times CHnFVAL[3:0])$  system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.

**Figure 42-218. Channel input filter example**

### 42.4.5 Output Compare mode

The Output Compare mode is selected when:

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$ , and
- $MSnB:MSnA = 0:1$

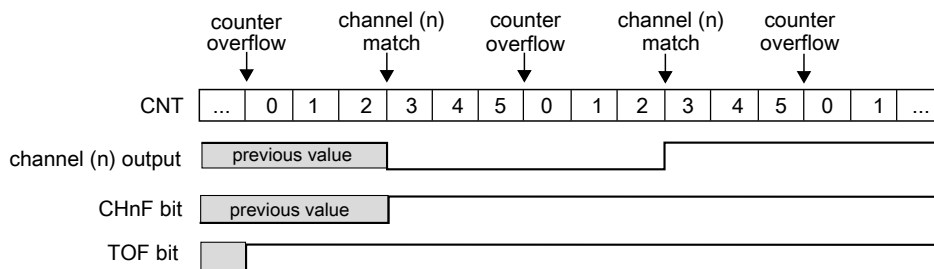

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the  $CnV$  register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

## functional description

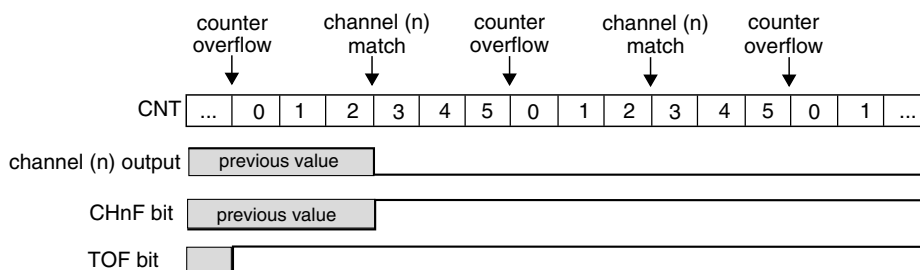

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

MOD = 0x0005  
CnV = 0x0003

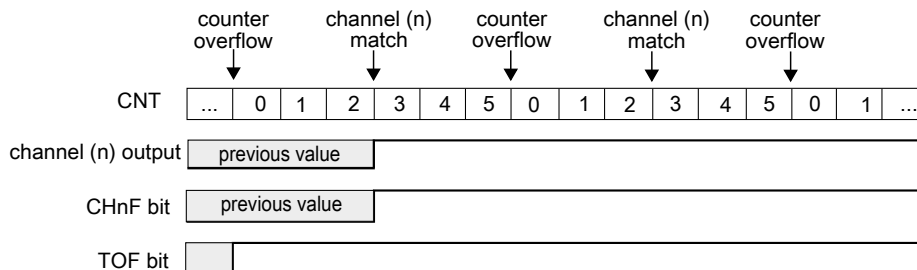

**Figure 42-219. Example of the Output Compare mode when the match toggles the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 42-220. Example of the Output Compare mode when the match clears the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 42-221. Example of the Output Compare mode when the match sets the channel output**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

## 42.4.6 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB = 1

The EPWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the pulse width (duty cycle) is determined by  $(CnV - CNTIN)$ .

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

**Figure 42-222. EPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

## functional description

MOD = 0x0008  
CnV = 0x0005

**Figure 42-223. EPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

**Figure 42-224. EPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match. If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

### Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if  $CNTIN < CnV \leq MOD$ ,
- 100% EPWM signal when  $CNTIN > CnV$  or  $CnV > MOD$ .

## 42.4.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

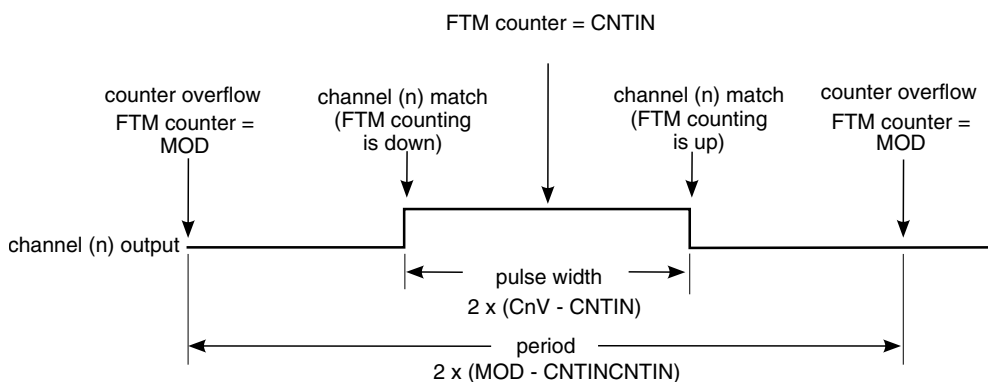

The CPWM pulse width (duty cycle) is determined by  $2 \times (CnV - CNTIN)$  and the period is determined by  $2 \times (MOD - CNTIN)$ . See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

**Figure 42-225. CPWM period and pulse width with ELSnB:ELSnA = 1:0**

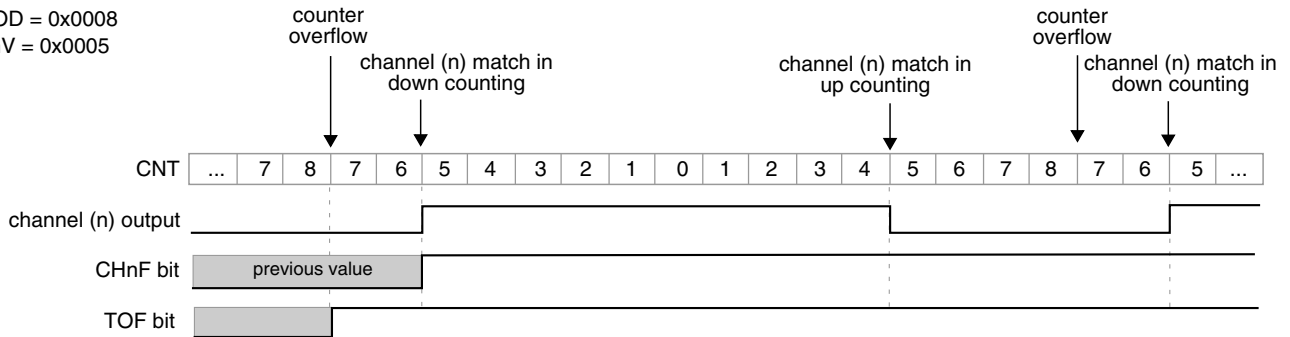

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

## functional description

MOD = 0x0008  
CnV = 0x0005

**Figure 42-226. CPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

MOD = 0x0008  
CnV = 0x0005

**Figure 42-227. CPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

### 42.4.8 Combine mode

The Combine mode is selected when:

- QUADEN = 0

- DECAPEN = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the PWM pulse width (duty cycle) is determined by  $(IC(n+1)V - C(n)V)$ .

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If  $(ELSnB:ELSnA = 1:0)$ , then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If  $(ELSnB:ELSnA = X:1)$ , then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output. However, if  $(ELSnB:ELSnA = 0:0)$  then the channel (n) output is not controlled by FTM, and if  $(ELSnB:ELSnA = 0:0)$  then the channel (n+1) output is not controlled by FTM.

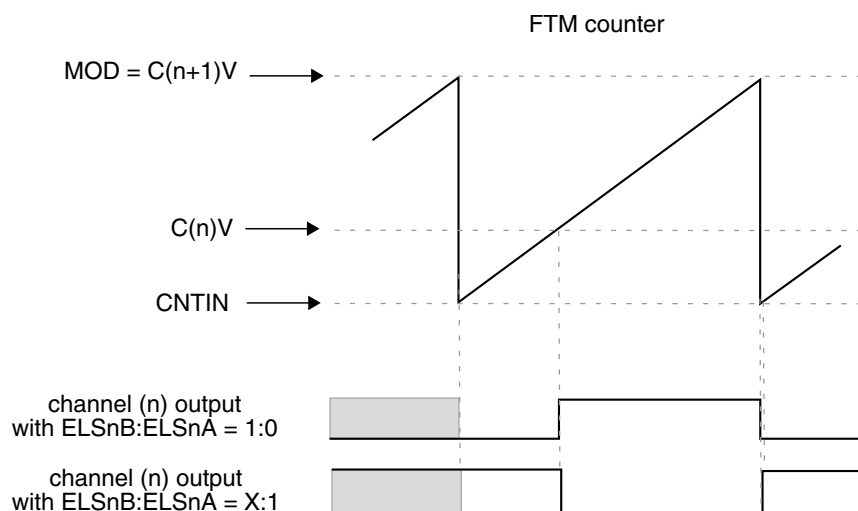

**Figure 42-228. Combine mode**

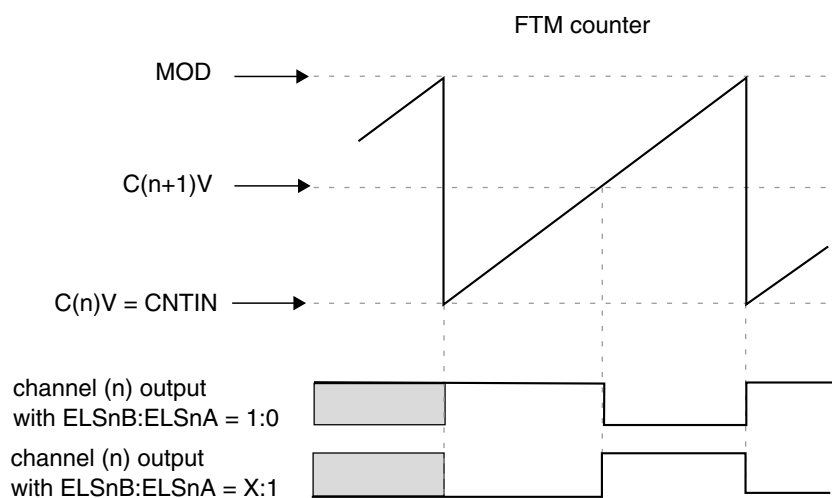

The following figures illustrate the PWM signals generation using Combine mode.

**Figure 42-229. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V < C(n+1)V)$**

**Figure 42-230. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n+1)V = MOD)$**

**Figure 42-231. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 42-232. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n)V$  is Almost Equal to  $CNTIN$ ) and  $(C(n+1)V = MOD)$**

**Figure 42-233. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n+1)V$  is Almost Equal to  $MOD$ )**

**Figure 42-234. Channel (n) output if C(n)V and C(n+1)V are not between CNTIN and MOD**

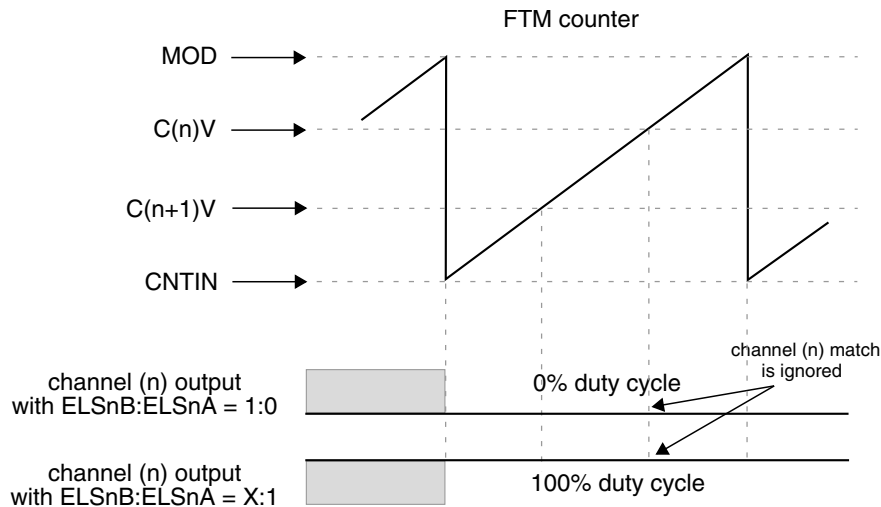

**Figure 42-235. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V = C(n+1)V)**

**Figure 42-236. Channel (n) output if  $(C(n)V = C(n+1)V = \text{CNTIN})$**

**Figure 42-237. Channel (n) output if  $(C(n)V = C(n+1)V = \text{MOD})$**

**Figure 42-238. Channel (n) output if  $(\text{CNTIN} < C(n)V < \text{MOD})$  and  $(\text{CNTIN} < C(n+1)V < \text{MOD})$  and  $(C(n)V > C(n+1)V)$**

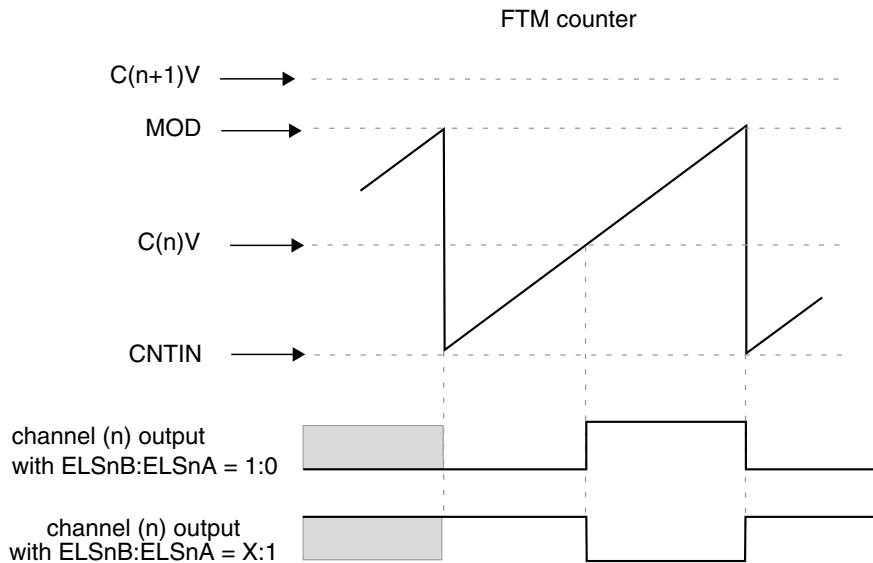

**Figure 42-239. Channel (n) output if  $C(n)V < CNTIN$  and  $CNTIN < C(n+1)V < MOD$**

**Figure 42-240. Channel (n) output if  $C(n+1)V < CNTIN$  and  $CNTIN < C(n)V < MOD$**

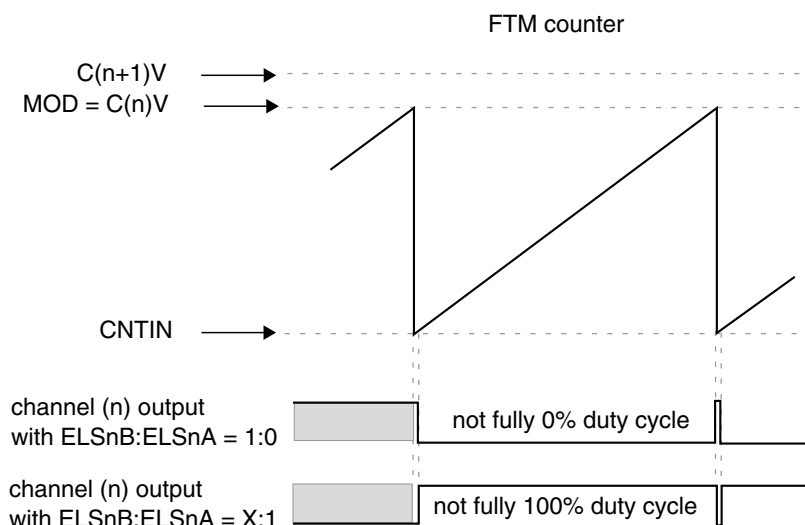

**Figure 42-241. Channel (n) output if  $(C(n)V > MOD)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 42-242. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V < MOD)$**

**Figure 42-243. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V = MOD)$**

### 42.4.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter =  $C(n)V$ , is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter =  $C(n+1)V$ . So, Combine mode allows the generation of asymmetrical PWM signals.

### 42.4.9 Complementary mode

The Complementary mode is selected when:

- $QUADEN = 0$
- $DECAPEN = 0$
- $COMP = 1$

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- $QUADEN = 0$
- $DECAPEN = 0$
- $COMP = 0$

**Figure 42-244. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = 1:0)**

**Figure 42-245. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = X:1)**

### NOTE

The complementary mode is not available in Output Compare mode.

## 42.4.10 Registers updated from write buffers

### 42.4.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

**Table 42-303. CNTIN register update**

| When  | Then CNTIN register is updated                            |
|---|---|
| CLKS[1:0] = 0:0   | When CNTIN register is written, independent of FTMEN bit. |
| <ul style="list-style-type: none"> <li>• FTMEN = 0, or</li> <li>• CNTINC = 0</li> </ul>                           | At the next system clock after CNTIN was written.         |
| <ul style="list-style-type: none"> <li>• FTMEN = 1,</li> <li>• SYNCMODE = 1, and</li> <li>• CNTINC = 1</li> </ul> | By the <a href="#">CNTIN register synchronization</a> .   |

### 42.4.10.2 MOD register update

The following table describes when MOD register is updated:

**Table 42-304. MOD register update**

| When  | Then MOD register is updated  |
|---|---|
| CLKS[1:0] = 0:0   | When MOD register is written, independent of FTMEN bit.   |
| <ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul> | According to the CPWMS bit, that is: <ul style="list-style-type: none"> <li>• If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul> |
| <ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul> | By the <a href="#">MOD register synchronization</a> .   |

### 42.4.10.3 CnV register update

The following table describes when CnV register is updated:

**Table 42-305. CnV register update**

| When  | Then CnV register is updated   |
|---|--|
| CLKS[1:0] = 0:0   | When CnV register is written, independent of FTMEN bit.  |
| <ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul> | According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written.</li> <li>• If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul> |
| <ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul> | According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> <li>• If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> </ul>   |

### 42.4.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

#### Note

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

#### 42.4.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGN = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGN bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGN bit, then the synchronization is initiated, but TRIGN bit remains set due to the write operation.

Note  
All hardware trigger inputs have the same behavior.

**Figure 42-246. Hardware trigger event with HWTRIGMODE = 0**

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

**NOTE**

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

**42.4.11.2 Software trigger**

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Boundary cycle and loading points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

**Figure 42-247. Software trigger event**

### 42.4.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In **Up counting** mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in **Up-down counting** mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

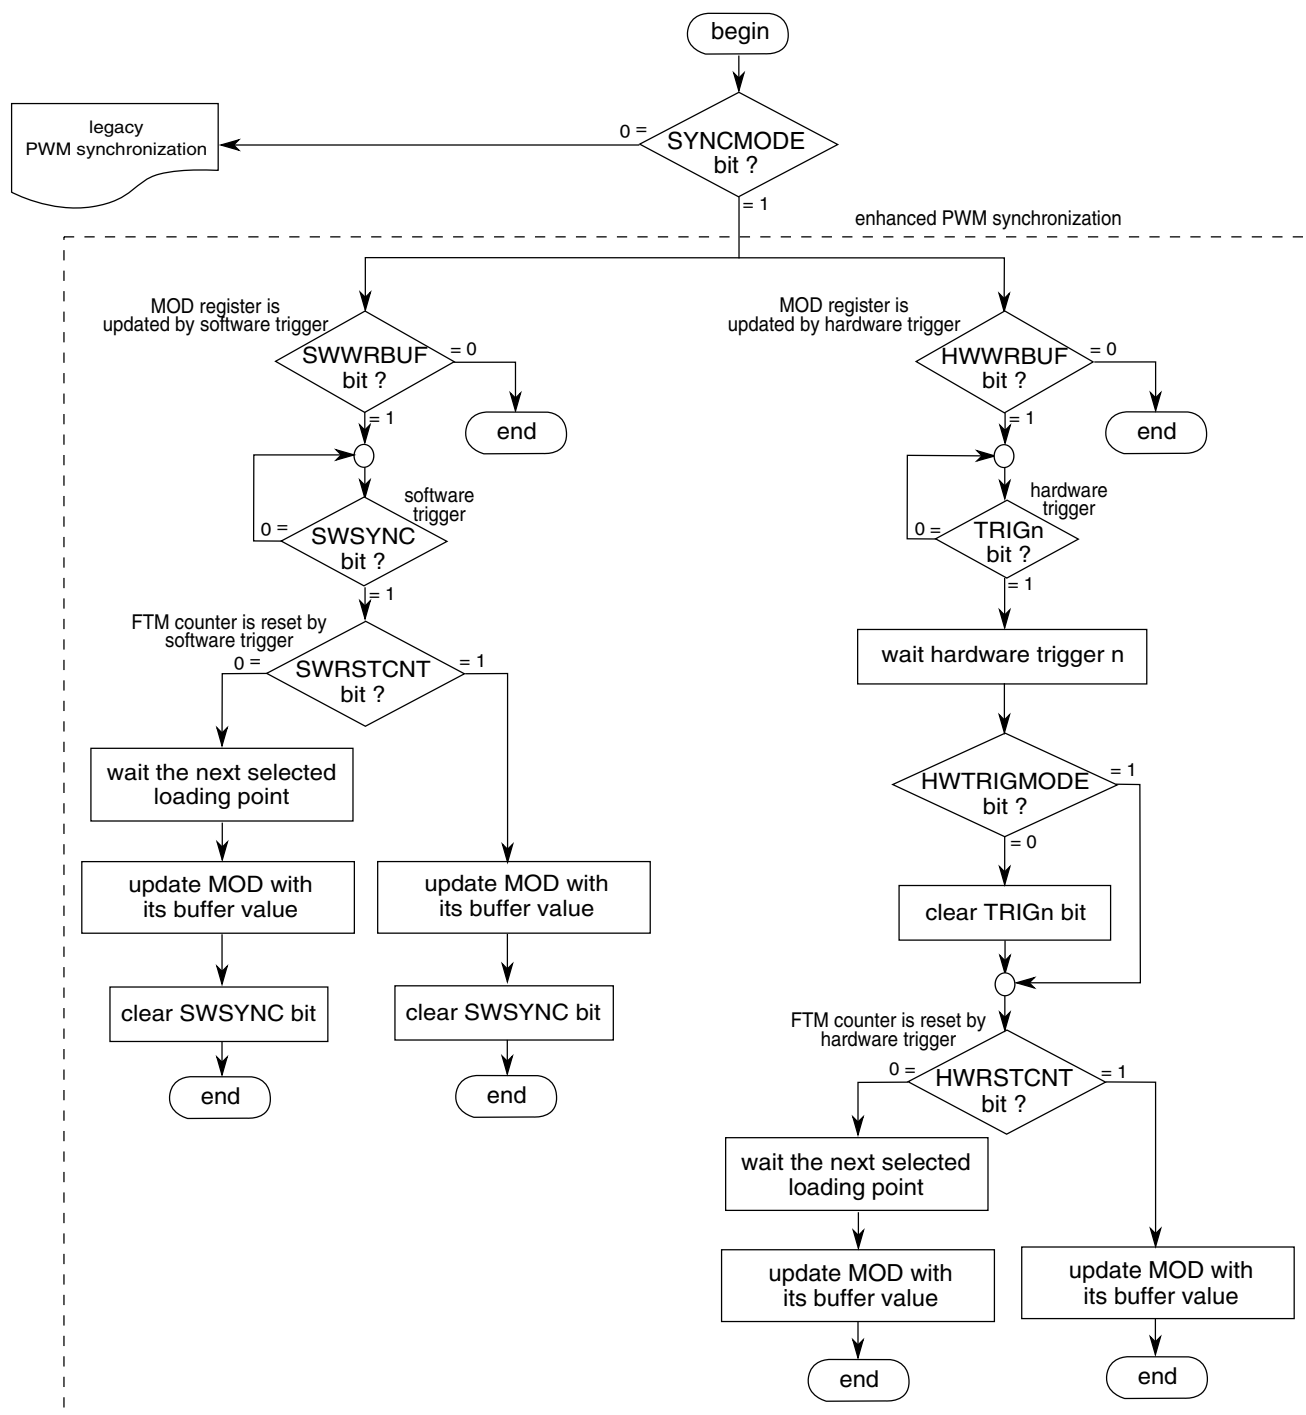

**Figure 42-248. Boundary cycles and loading points**

#### 42.4.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if ( $FTMEN = 1$ ).

The MOD register synchronization can be done by either the enhanced PWM synchronization ( $SYNCMODE = 1$ ) or the legacy PWM synchronization ( $SYNCMODE = 0$ ). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on  $SWWRBUF$ ,  $SWRSTCNT$ ,  $HWWRBUF$ , and  $HWRSTCNT$  bits according to this flowchart:

**Figure 42-249. MOD register synchronization flowchart**

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected

loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGN) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 42-250. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used**

**Figure 42-251. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 42-252. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used**

**Figure 42-253. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used**

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

**Figure 42-254. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)**

### 42.4.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

### 42.4.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

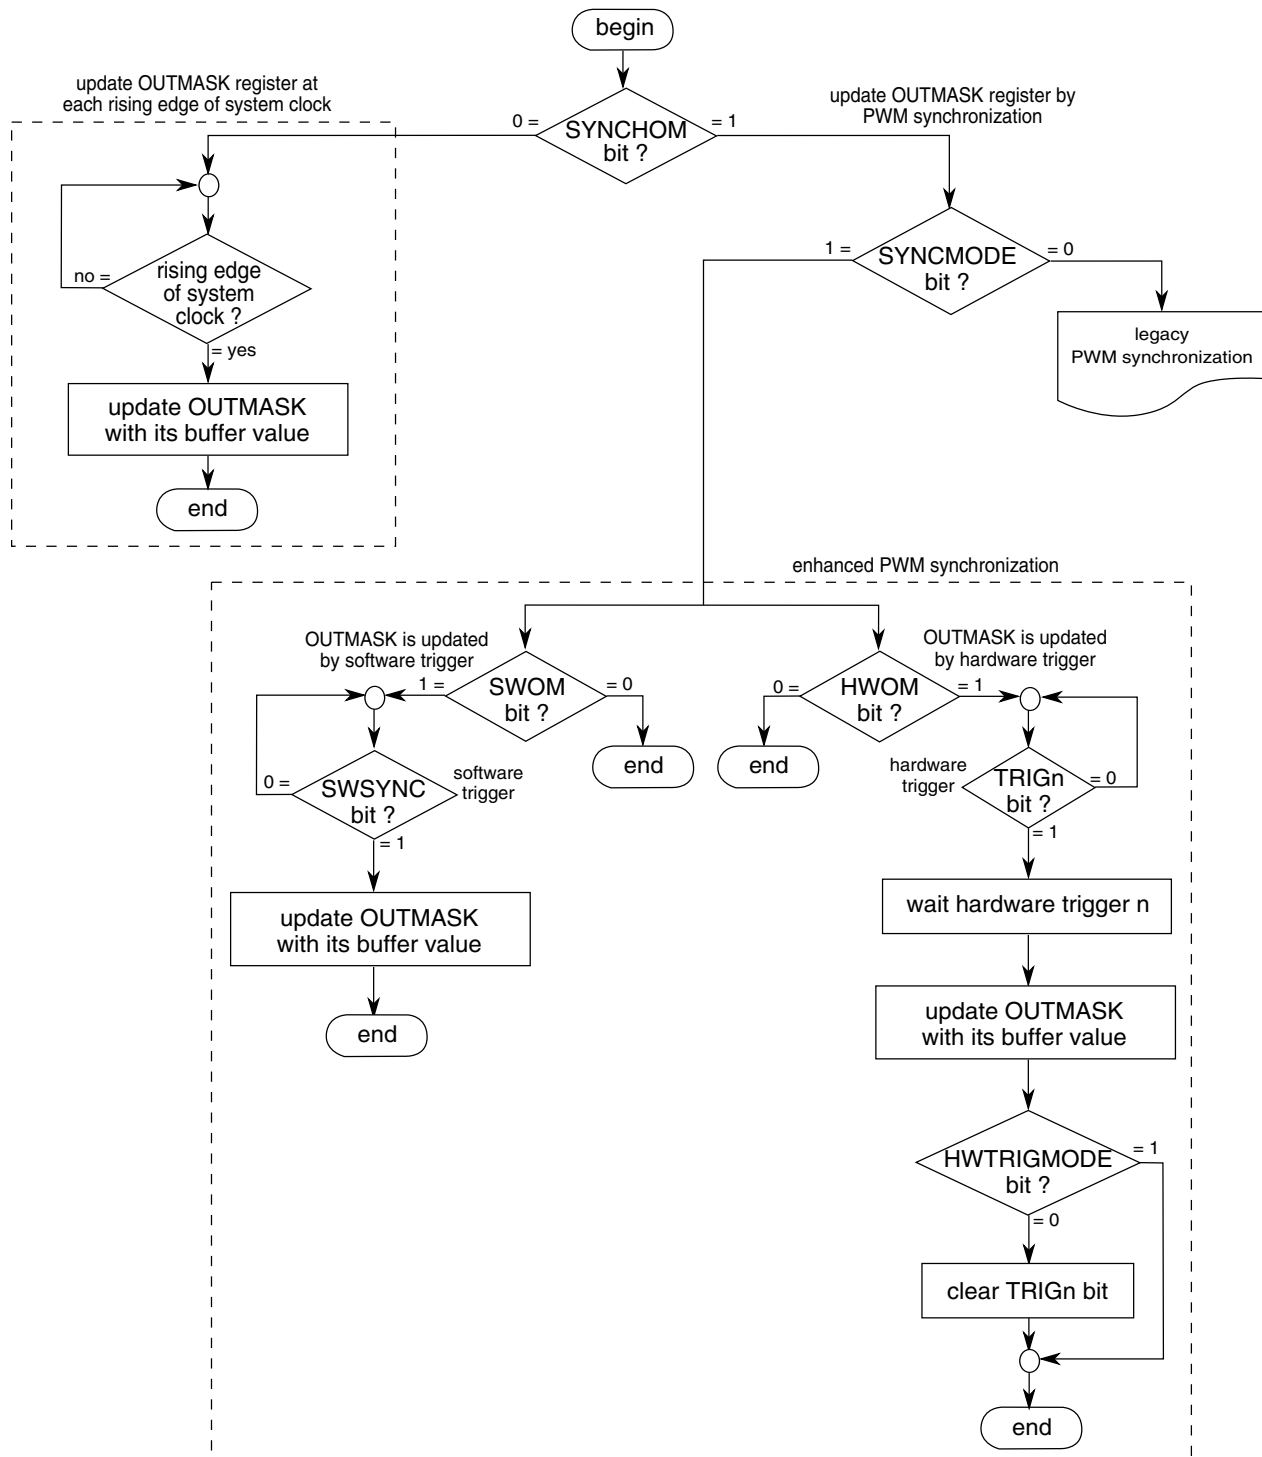

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

### 42.4.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

**Figure 42-255. OUTMASK register synchronization flowchart**

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 42-256. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used**

**Figure 42-257. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

**Figure 42-258. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used**

#### 42.4.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 42-259. INVCTRL register synchronization flowchart

### 42.4.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

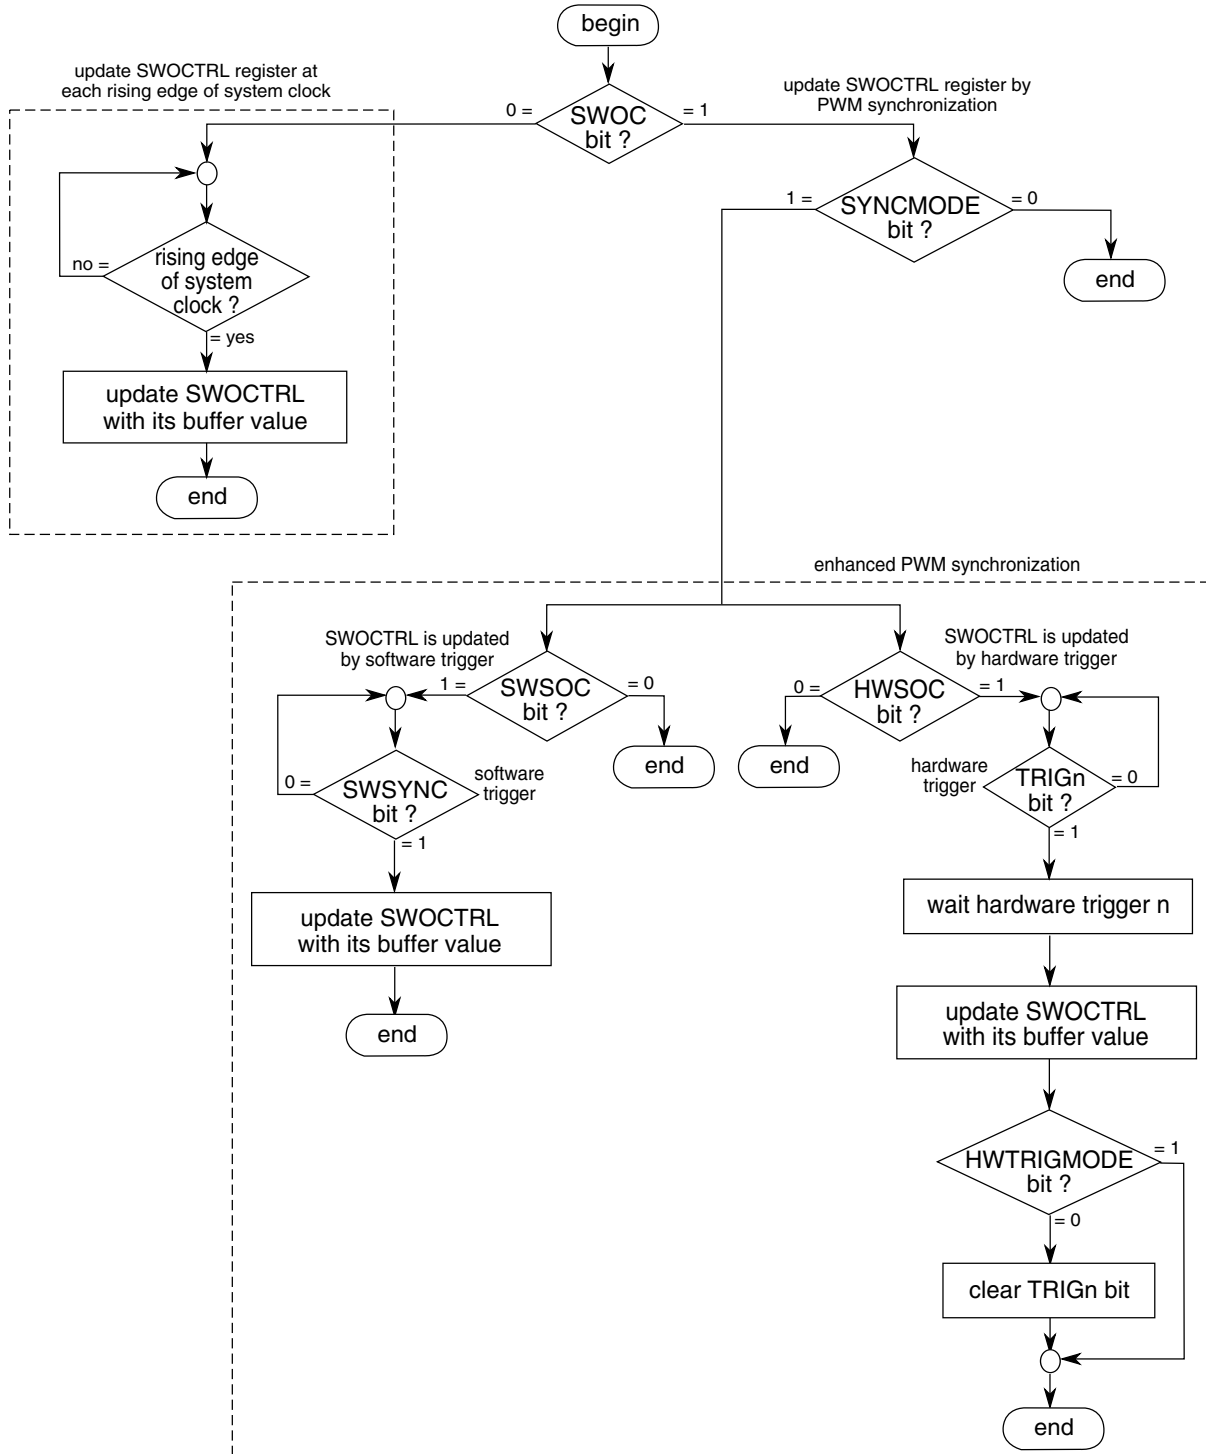

Figure 42-260. SWOCTRL register synchronization flowchart

### 42.4.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n + 1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

**Figure 42-261. FTM counter synchronization**

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

**Figure 42-262. FTM counter synchronization flowchart**

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 42-263. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used**

**Figure 42-264. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

**Figure 42-265. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used**

## 42.4.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INV<sub>m</sub> = 1 (where m represents a channel pair)

The INV<sub>m</sub> bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#)

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

NOTE

INV<sub>m</sub> bit selects the inverting to the pair channels (n) and (n+1).

**Figure 42-266. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode**

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE  
INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 42-267. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode**

**Note**

The inverting feature is not available in Output Compare mode.

**42.4.13 Software output control**

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

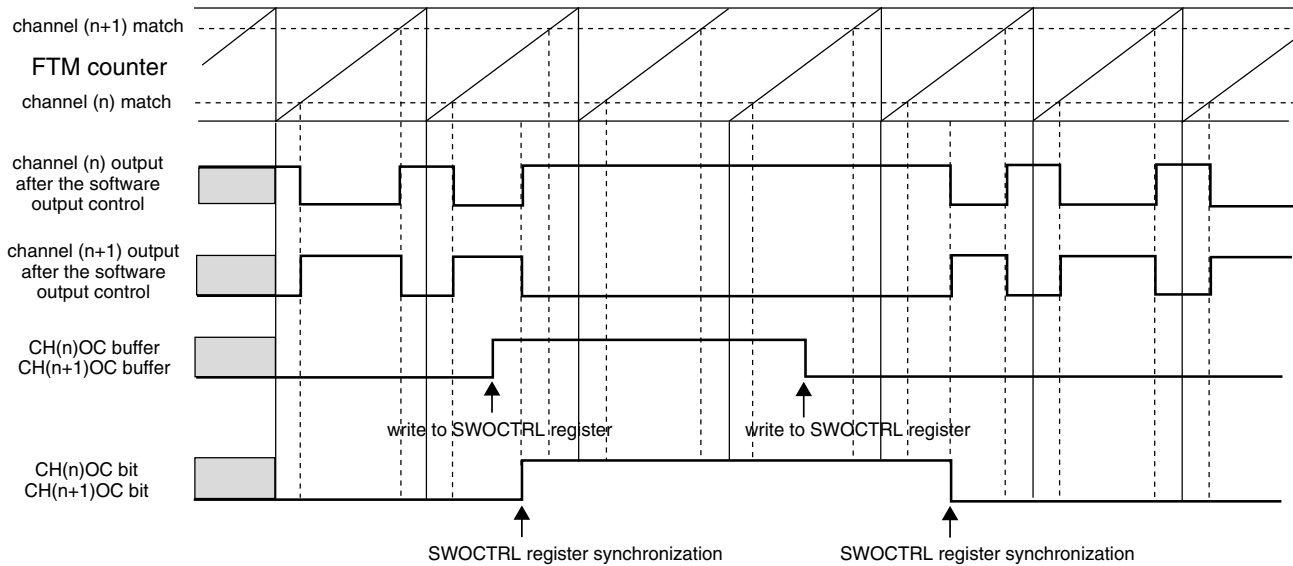

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE  
CH(n)OCV = 1 and CH(n+1)OCV = 0.

**Figure 42-268. Example of software output control in Combine and Complementary mode**

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

**Table 42-306. Software output control behavior when (COMP = 0)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to one        |

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

**Table 42-307. Software output control behavior when (COMP = 1)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to zero       |

**Note**

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

### 42.4.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared.

**Figure 42-269. Deadtime insertion with  $ELSnB:ELSnA = 1:0$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

**Figure 42-270. Deadtime insertion with  $ELSnB:ELSnA = X:1$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

### NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

### 42.4.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ( $(C(n+1)V - C(n)V) \times \text{system clock}$ ), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ( $(\text{MOD} - \text{CNTIN} + 1 - (C(n+1)V - C(n)V)) \times \text{system clock}$ ), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

**Figure 42-271. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle**

**Figure 42-272. Example of the deadtime insertion ( $ELSnB:ELSnA = 1:0$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$ ) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle**

### 42.4.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If  $CHnOM = 1$ , then the channel (n) output is forced to its inactive state ( $POLn$  bit value). If  $CHnOM = 0$ , then the channel (n) output is unaffected by the output mask. See the following figure.

**Figure 42-273. Output mask with POLn = 0**

The following table shows the output mask result before the polarity control.

**Table 42-308. Output mask result for channel (n) before the polarity control**

| CHnOM | Output Mask Input | Output Mask Result |
|-------|-------------------|--------------------|
| 0     | inactive state    | inactive state     |
|       | active state      | active state       |
| 1     | inactive state    | inactive state     |
|       | active state      | inactive state     |

### 42.4.16 Fault control

The fault control is enabled if (FAULTM[1:0] ≠ 0:0).

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter is reset and starts counting up. As long as the new state is stable on the fault input n, the

counter continues to increment. If the 5-bit counter overflows, that is, the counter exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits ( $\times$  system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case, the fault input n signal is delayed 2 rising edges of the system clock and the FAULTFn bit is set on 3th rising edge of the system clock after a rising edge occurs on the fault input n.

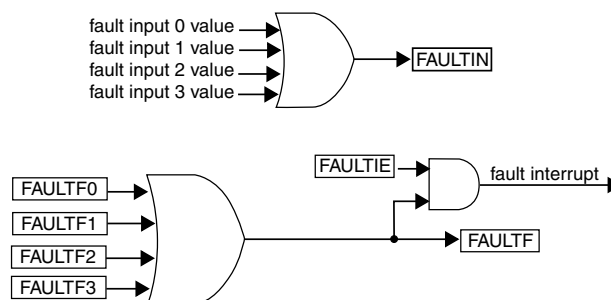

If FFVAL[3:0]  $\neq$  0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock, that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

\* where n = 3, 2, 1, 0

**Figure 42-274. Fault input n control block diagram**

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

**Figure 42-275. FAULTF and FAULTIN bits and fault interrupt**

## functional description

If the fault control is enabled ( $\text{FAULTM}[1:0] \neq 0:0$ ), a fault condition has occurred and ( $\text{FAULTEN} = 1$ ), then outputs are forced to their safe values:

- Channel (n) output takes the value of  $\text{POL}(n)$
- Channel (n+1) takes the value of  $\text{POL}(n+1)$

The fault interrupt is generated when ( $\text{FAULTF} = 1$ ) and ( $\text{FAULTIE} = 1$ ). This interrupt request remains set until:

- Software clears the  $\text{FAULTF}$  bit by reading  $\text{FAULTF}$  bit as 1 and writing 0 to it
- Software clears the  $\text{FAULTIE}$  bit
- A reset occurs

### 42.4.16.1 Automatic fault clearing

If the automatic fault clearing is selected ( $\text{FAULTM}[1:0] = 1:1$ ), then the channels output disabled by fault control is again enabled when the fault input signal ( $\text{FAULTIN}$ ) returns to zero and a new PWM cycle begins. See the following figure.

**Figure 42-276. Fault control with automatic fault clearing**

### 42.4.16.2 Manual fault clearing

If the manual fault clearing is selected ( $FAULTM[1:0] = 0:1$  or  $1:0$ ), then the channels output disabled by fault control is again enabled when the  $FAULTF$  bit is cleared and a new PWM cycle begins. See the following figure.

NOTE  
The channel (n) output is after the fault control with manual fault clearing and  $POLn = 0$ .

**Figure 42-277. Fault control with manual fault clearing**

### 42.4.16.3 Fault inputs polarity control

The  $FLTjPOL$  bit selects the fault input  $j$  polarity, where  $j = 0, 1, 2, 3$ :

- If  $FLTjPOL = 0$ , the fault  $j$  input polarity is high, so the logical one at the fault input  $j$  indicates a fault.
- If  $FLTjPOL = 1$ , the fault  $j$  input polarity is low, so the logical zero at the fault input  $j$  indicates a fault.

## 42.4.17 Polarity control

The  $POLn$  bit selects the channel (n) output polarity:

- If  $POL_n = 0$ , the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If  $POL_n = 1$ , the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

### 42.4.18 Initialization

The initialization forces the  $CH_nOI$  bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

**Table 42-309. Initialization behavior when (COMP = 0 and DTEN = 0)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | 0         | is forced to zero  | is forced to zero    |
| 0       | 1         | is forced to zero  | is forced to one     |
| 1       | 0         | is forced to one   | is forced to zero    |
| 1       | 1         | is forced to one   | is forced to one     |

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

**Table 42-310. Initialization behavior when (COMP = 1 or DTEN = 1)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | X         | is forced to zero  | is forced to one     |
| 1       | X         | is forced to one   | is forced to zero    |

#### Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

### 42.4.19 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

pair channels (m) - channels (n) and (n+1)

**NOTE**

The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

**Figure 42-278. Priority of the features used at the generation of channels (n) and (n+1) outputs signals**

**Note**

The **Initialization** feature must not be used with **Inverting** and **Software output control** features.

**42.4.20 Channel trigger output**

If CHjTRIG = 1, where j = 0, 1, 2, 3, 4, or 5, then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal that is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

**NOTE**

- (a) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0
- (b) CH0TRIG = 1, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0
- (c) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1
- (d) CH0TRIG = 1, CH1TRIG = 1, CH2TRIG = 1, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1

**Figure 42-279. Channel match trigger**

### 42.4.21 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.

- When there is the **FTM counter synchronization**.
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.

The following figures show these cases.

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

**Figure 42-280. Initialization trigger is generated when the FTM counting achieves the CNTIN register value**

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

**Figure 42-281. Initialization trigger is generated when there is a write to CNT register**

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

**Figure 42-282. Initialization trigger is generated when there is the FTM counter synchronization**

functional description

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

**Figure 42-283. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits**

The initialization trigger output provides a trigger signal that is used for on-chip modules.

### 42.4.22 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for [Input Capture mode](#) and FTM counter must be configured to the [Up counting](#).

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

NOTE

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 42-284. Capture Test mode

### 42.4.23 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

Table 42-311. Channel DMA transfer request

| DMA | CHnIE | Channel DMA Transfer Request                                 | Channel Interrupt                                 |
|-----|-------|--|---|
| 0   | 0     | The channel DMA transfer request is not generated.           | The channel interrupt is not generated.           |
| 0   | 1     | The channel DMA transfer request is not generated.           | The channel interrupt is generated if (CHnF = 1). |
| 1   | 0     | The channel DMA transfer request is not generated.           | The channel interrupt is not generated.           |
| 1   | 1     | The channel DMA transfer request is generated if (CHnF = 1). | The channel interrupt is not generated.           |

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

**Table 42-312. Clear CHnF bit when DMA = 1**

| CHnIE | How CHnF Bit Can Be Cleared   |
|-------|---|
| 0     | CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit. |
| 1     | CHnF bit is cleared when the channel DMA transfer is done.  |

### 42.4.24 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

\* Filtering function for dual edge capture mode is only available in the channels 0 and 2

**Figure 42-285. Dual Edge Capture mode block diagram**

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The  $C(n)V$  register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The  $C(n+1)V$  register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the  $C(n)V$  and  $C(n+1)V$  registers are read. The only requirement is that  $C(n)V$  must be read before  $C(n+1)V$ .

### Note

- The  $CH(n)F$ ,  $CH(n)IE$ ,  $MS(n)A$ ,  $ELS(n)B$ , and  $ELS(n)A$  bits are channel (n) bits.
- The  $CH(n+1)F$ ,  $CH(n+1)IE$ ,  $MS(n+1)A$ ,  $ELS(n+1)B$ , and  $ELS(n+1)A$  bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with  $ELS(n)B:ELS(n)A = 0:1$  or  $1:0$ ,  $ELS(n+1)B:ELS(n+1)A = 0:1$  or  $1:0$  and the FTM counter in [Free running counter](#).

#### 42.4.24.1 One-Shot Capture mode

The One-Shot Capture mode is selected when ( $DECAPEN = 1$ ), and ( $MS(n)A = 0$ ). In this capture mode, only one pair of edges at the channel (n) input is captured. The  $ELS(n)B:ELS(n)A$  bits select the first edge to be captured, and  $ELS(n+1)B:ELS(n+1)A$  bits select the second edge to be captured.

The edge captures are enabled while  $DECAP$  bit is set. For each new measurement in One-Shot Capture mode, first the  $CH(n)F$  and  $CH(n+1)$  bits must be cleared, and then the  $DECAP$  bit must be set.

In this mode, the  $DECAP$  bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while  $DECAP$  bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the  $C(n)V$  and  $C(n+1)V$  registers.

Similarly, when the  $CH(n+1)F$  bit is set, both edges were captured and the captured values are ready for reading in the  $C(n)V$  and  $C(n+1)V$  registers.

### 42.4.24.2 Continuous Capture mode

The Continuous Capture mode is selected when ( $DECAPEN = 1$ ), and ( $MS(n)A = 1$ ). In this capture mode, the edges at the channel (n) input are captured continuously. The  $ELS(n)B:ELS(n)A$  bits select the initial edge to be captured, and  $ELS(n+1)B:ELS(n+1)A$  bits select the final edge to be captured.

The edge captures are enabled while  $DECAP$  bit is set. For the initial use, first the  $CH(n)F$  and  $CH(n+1)F$  bits must be cleared, and then  $DECAP$  bit must be set to start the continuous measurements.

When the  $CH(n+1)F$  bit is set, both edges were captured and the captured values are ready for reading in the  $C(n)V$  and  $C(n+1)V$  registers. The latest captured values are always available in these registers even after the  $DECAP$  bit is cleared.

In this mode, it is possible to clear only the  $CH(n+1)F$  bit. Therefore, when the  $CH(n+1)F$  bit is set again, the latest captured values are available in  $C(n)V$  and  $C(n+1)V$  registers.

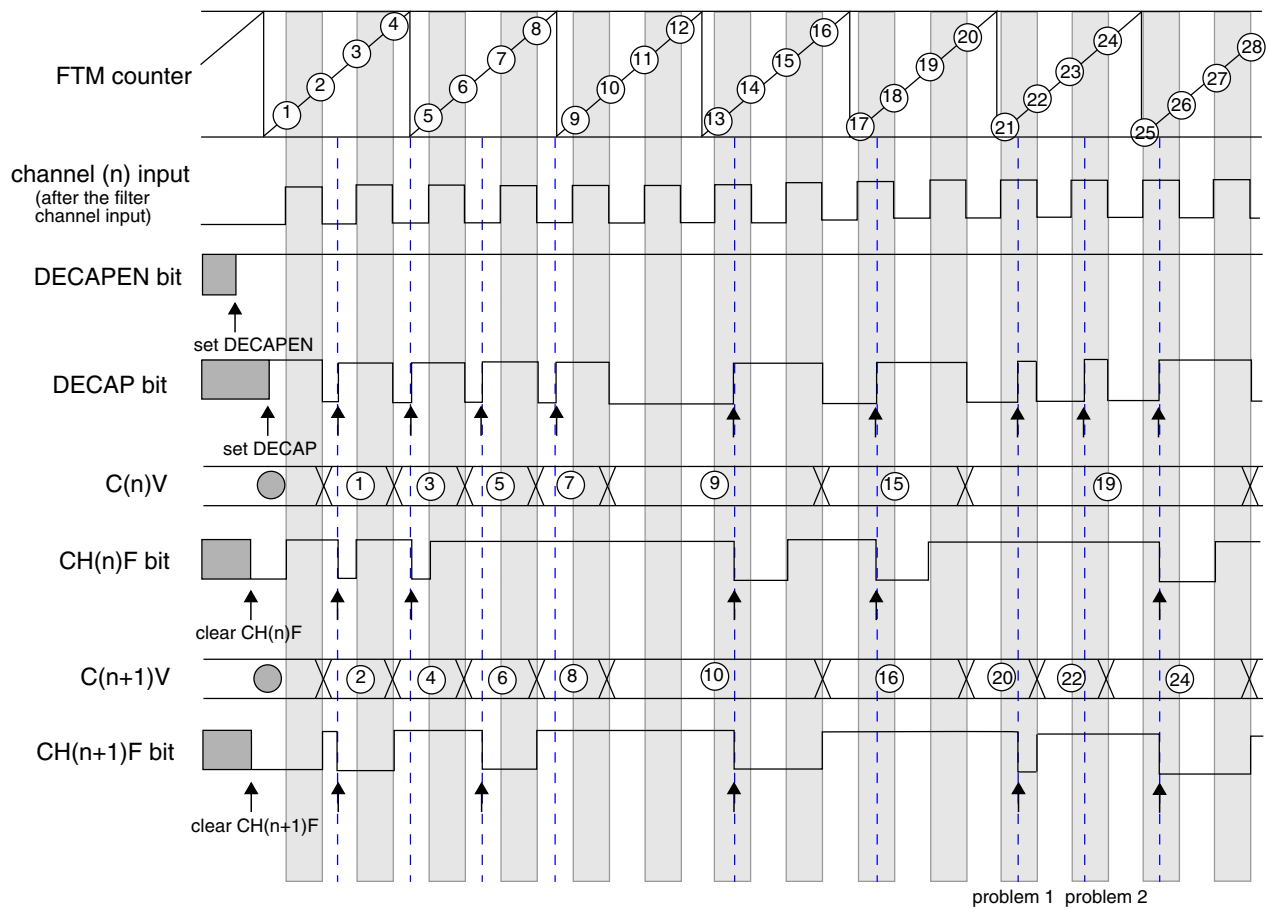

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the  $CH(n)F$  and  $CH(n+1)F$  bits to start new measurements.

### 42.4.24.3 Pulse width measurement

If the channel (n) is configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$ ) and the channel (n+1) to capture falling edges ( $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$ ) and the channel (n+1) to capture rising edges ( $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The  $DECAPEN$  bit selects the Dual Edge Capture mode, so it remains set. The  $DECAP$  bit is set to enable the measurement of next positive polarity pulse width. The  $CH(n)F$  bit is set when the first edge of this pulse is detected, that is, the edge selected by  $ELS(n)B:ELS(n)A$  bits. The  $CH(n+1)F$  bit is set and  $DECAP$  bit is cleared when the second edge of this pulse is detected, that is, the edge selected by  $ELS(n+1)B:ELS(n+1)A$  bits. Both  $DECAP$  and  $CH(n+1)F$  bits indicate when two edges of the pulse were captured and the  $C(n)V$  and  $C(n+1)V$  registers are ready for reading.

## Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 42-286. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note  
 - The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

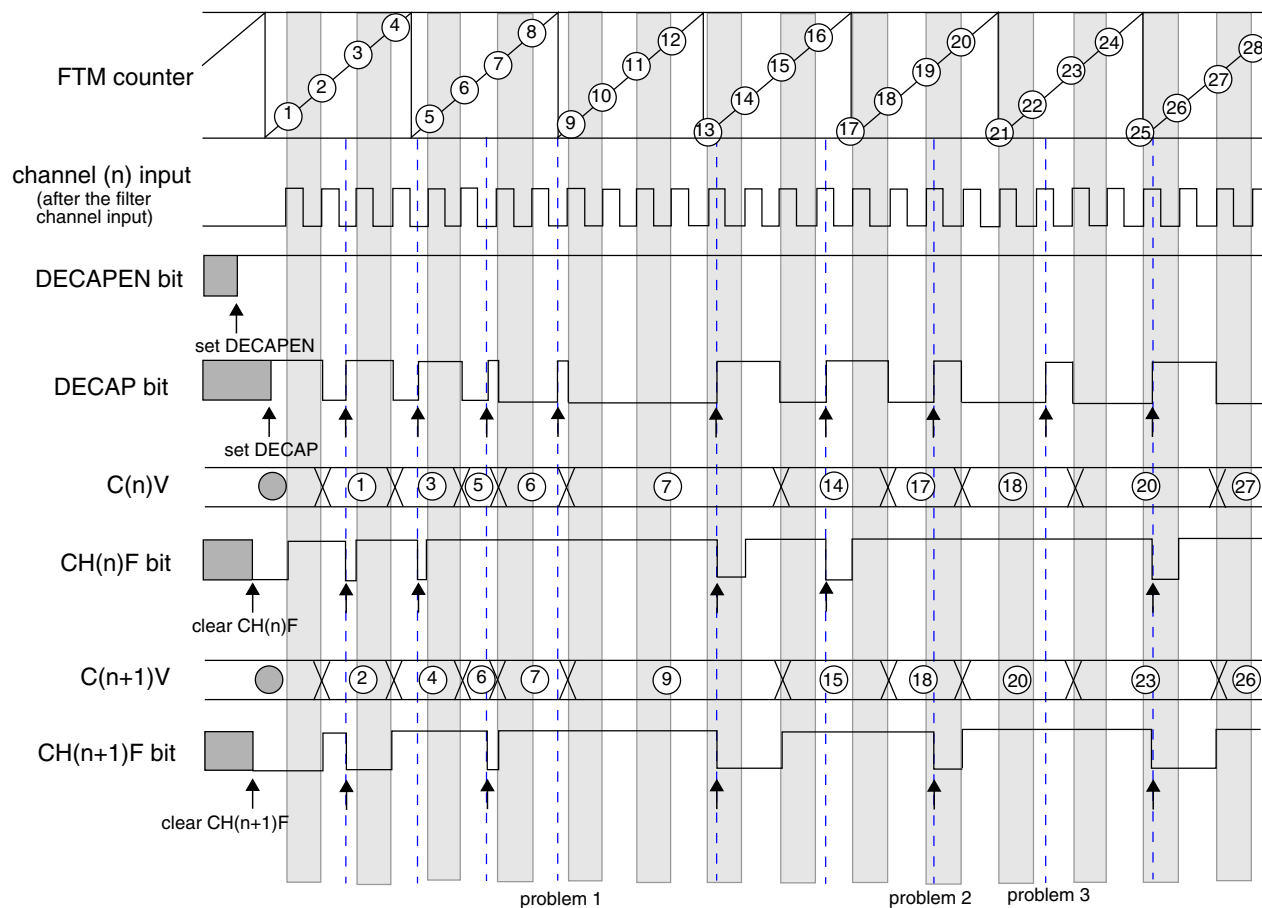

**Figure 42-287. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement**

#### 42.4.24.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$  and  $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$  and  $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

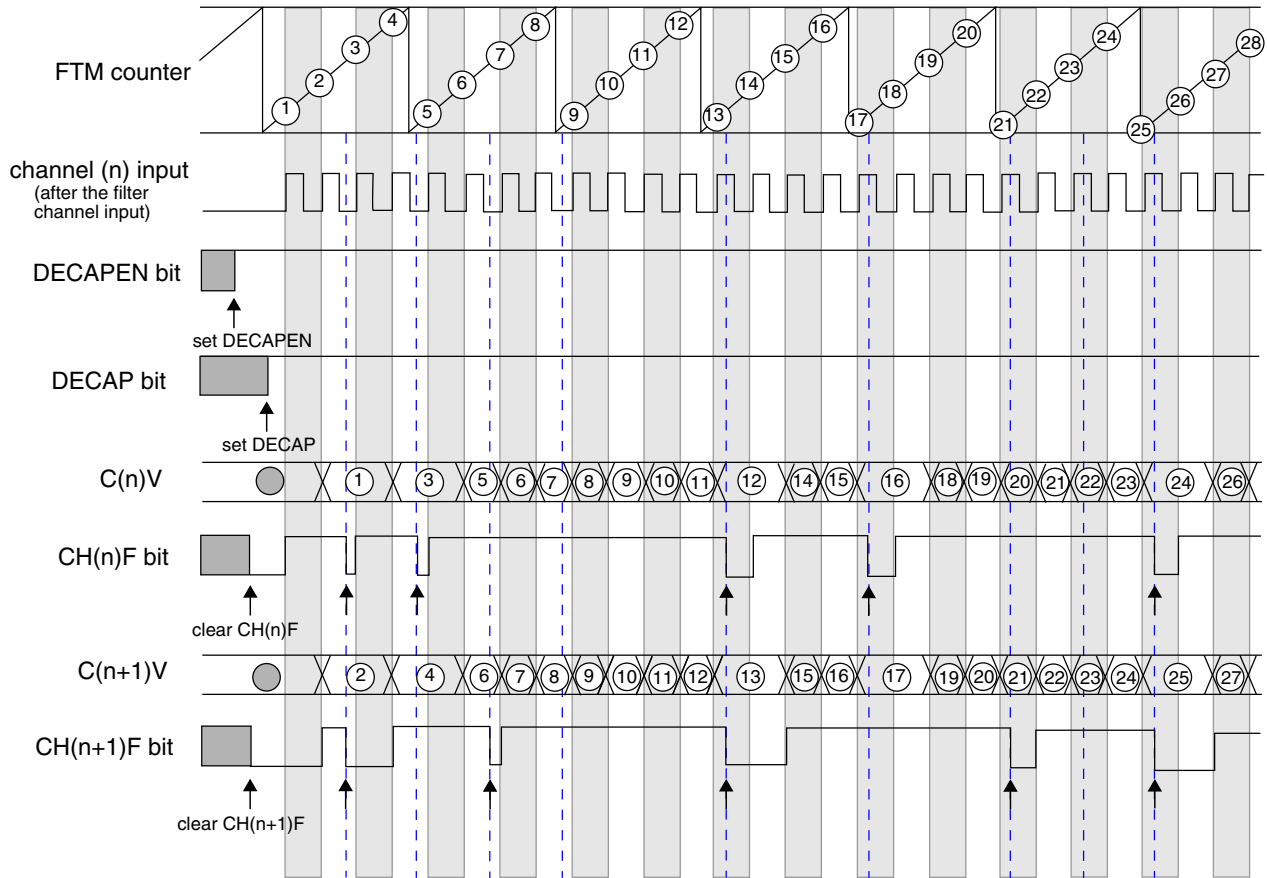

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 42-288. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set

when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note  
 - The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 42-289. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges**

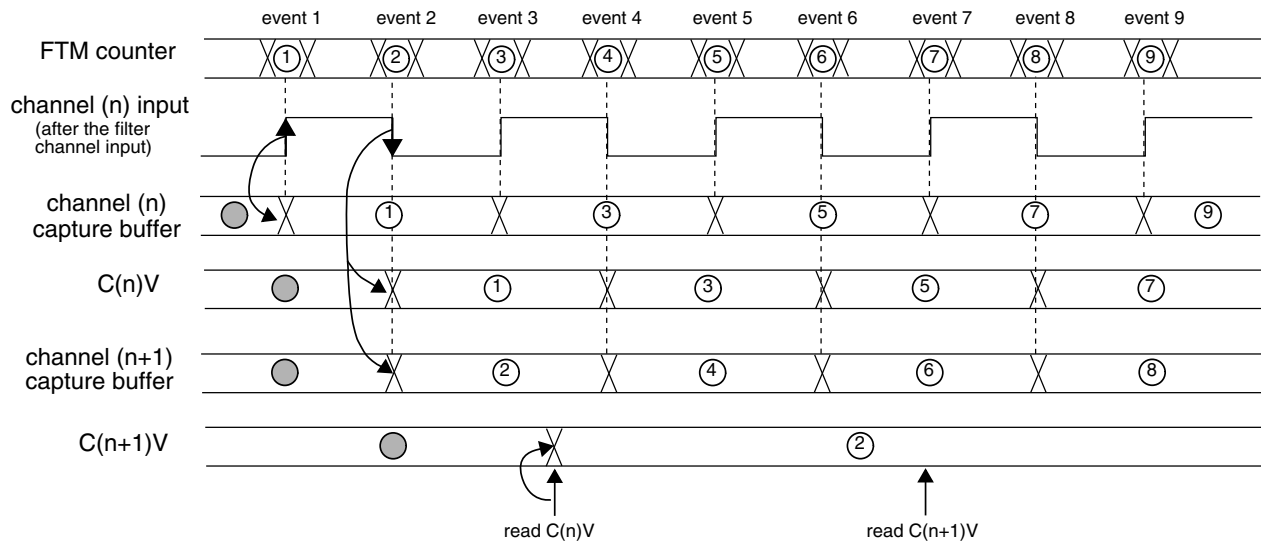

### 42.4.24.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

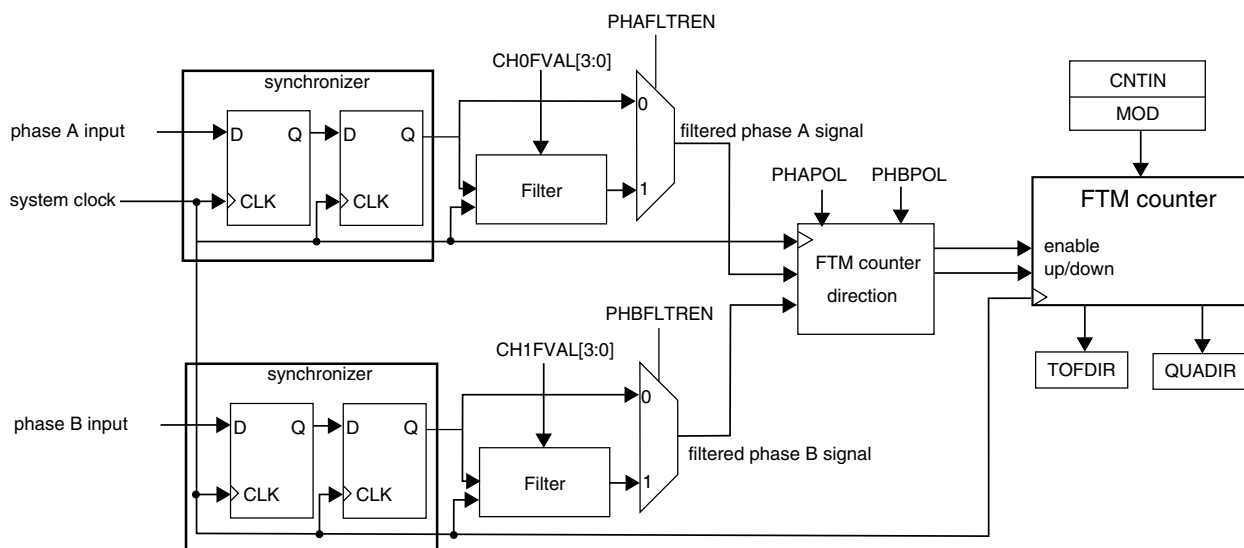

**Figure 42-290. Dual Edge Capture mode read coherency mechanism**

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

### 42.4.25 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

**Figure 42-291. Quadrature Decoder block diagram**

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; [Filter for Input Capture mode](#). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

**Note**

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

**Note**

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

**Figure 42-292. Quadrature Decoder – Count and Direction Encoding mode**

If QUADMODE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

**functional description**

**Figure 42-293. Quadrature Decoder – Phase A and Phase B Encoding mode**

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

**Figure 42-294. FTM Counter overflow in up counting for Quadrature Decoder mode**

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

**Figure 42-295. FTM counter overflow in down counting for Quadrature Decoder mode**

### 42.4.25.1 Quadrature Decoder boundary conditions

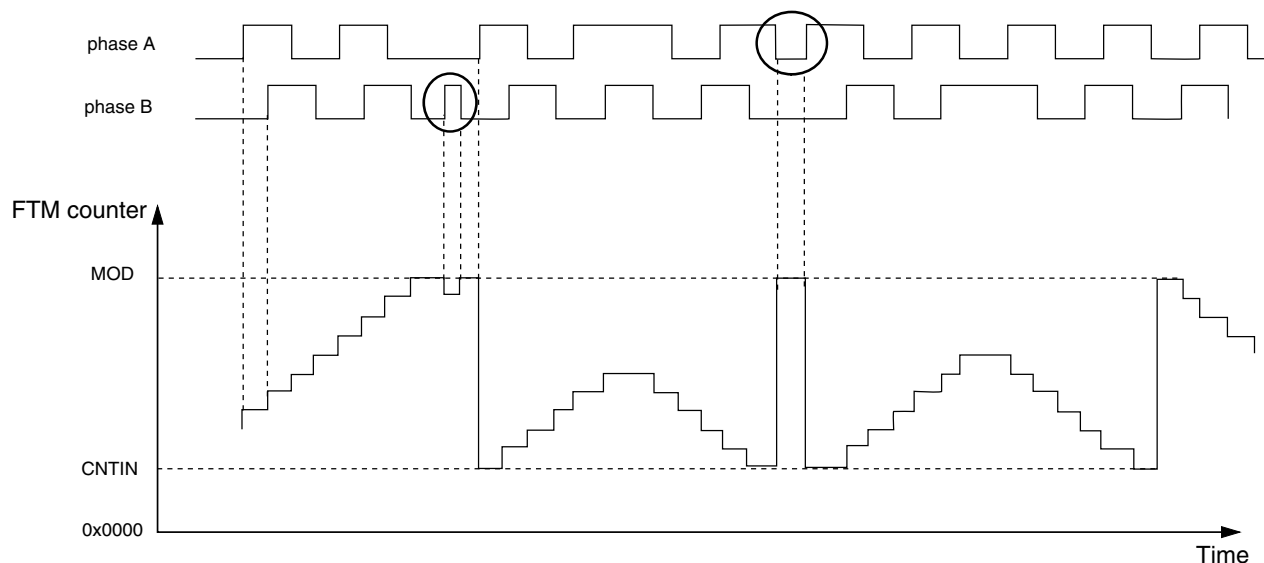

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

**Figure 42-296. Motor position jittering in a mid count value**

The following figure shows motor jittering produced by the phase B and A pulses respectively:

**Figure 42-297. Motor position jittering near maximum and minimum count value**

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

### 42.4.26 BDM mode

When the chip is in BDM mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the CH(n)F bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

**Table 42-313. FTM behavior when the chip is in BDM mode**

| BDMMODE | FTM Counter | CH(n)F Bit | FTM Channels Output   | Writes to MOD, CNTIN, and C(n)V Registers              |
|---------|-------------|------------|---|--|
| 00      | Stopped     | can be set | Functional mode   | Writes to these registers bypass the registers buffers |
| 01      | Stopped     | is not set | The channels outputs are forced to their safe value according to POLn bit | Writes to these registers bypass the registers buffers |
| 10      | Stopped     | is not set | The channels outputs are frozen when the chip enters in BDM mode          | Writes to these registers bypass the registers buffers |

*Table continues on the next page...*

**Table 42-313. FTM behavior when the chip is in BDM mode (continued)**

| BDMMODE | FTM Counter     | CH(n)F Bit | FTM Channels Output | Writes to MOD, CNTIN, and C(n)V Registers |
|---------|-----------------|------------|---------------------|---|
| 11      | Functional mode | can be set | Functional mode     | Functional mode                           |

Note that if  $BDMMODE[1:0] = 2'b00$  then the channels outputs remain at the value when the chip enters in BDM mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this BDM mode.

- Write any value to CNT register; see [Counter reset](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see [FTM counter synchronization](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See [Initialization](#).

### Note

The  $BDMMODE[1:0] = 2'b00$  must not be used with the [Fault control](#). Even if the fault control is enabled and a fault condition exists, the channels outputs values are updated as above.

### Note

If  $CLKS[1:0] = 2'b00$  in BDM, a non-zero value is written to CLKS in BDM, and  $CnV = CNTIN$  when the BDM is disabled, then the CHnF bit is set (since if the channel is a 0% EPWM signal) when the BDM is disabled.

## 42.4.27 Intermediate load

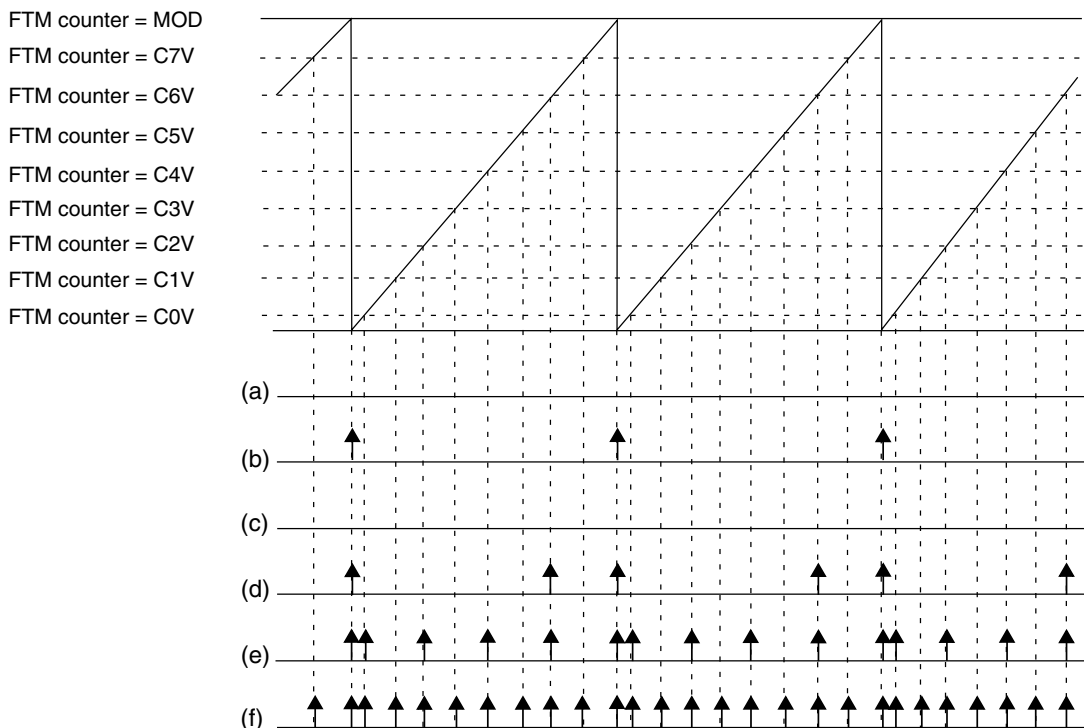

The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

**Table 42-314. When possible loading points are enabled**

| Loading point  | Enabled         |
|--|-----------------|
| When the FTM counter wraps from MOD value to CNTIN value | Always          |
| At the channel (j) match (FTM counter = C(j)V)           | When CHjSEL = 1 |

The following figure shows some examples of enabled loading points.

**NOTE**

- (a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
- (b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
- (c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
- (d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
- (e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
- (f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

**Figure 42-298. Loading points for intermediate load**

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

**Table 42-315. Conditions for loads occurring at the next enabled loading point**

| When a new value was written | Then   |
|------------------------------|--|
| To the MOD register          | The MOD register is updated with its write buffer value. |

Table continues on the next page...

**Table 42-315. Conditions for loads occurring at the next enabled loading point (continued)**

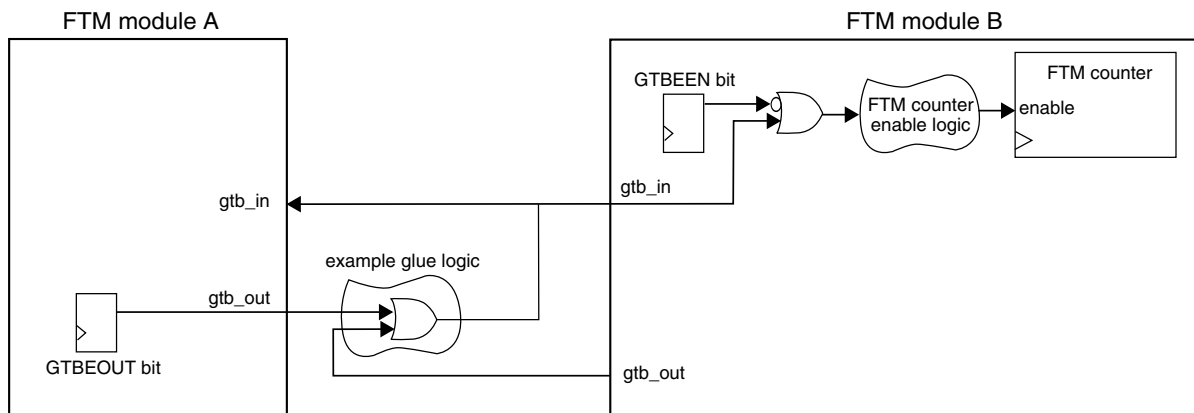

| When a new value was written  | Then   |
|---|--|
| To the CNTIN register and CNTINC = 1  | The CNTIN register is updated with its write buffer value.   |
| To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)   | The C(n)V register is updated with its write buffer value.   |
| To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1) | The C(n+1)V register is updated with its write buffer value. |

### NOTE

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero, then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

## 42.4.28 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 42-299. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb\_in*, and the output signal *gtb\_out*. The GTBEEN bit enables *gtb\_in* to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when *gtb\_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb\_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb\_in* and *gtb\_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

### NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the *gtb\_in* signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

#### 42.4.28.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

## 42.5 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

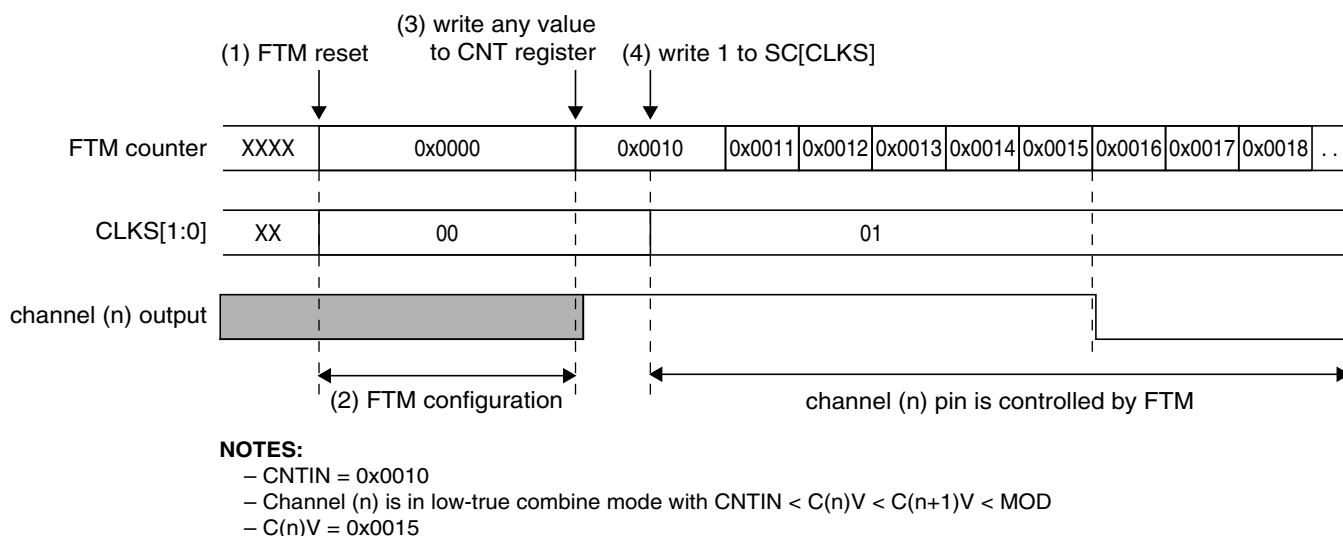

- the FTM counter and the prescaler counter are zero and are stopped ( $CLKS[1:0] = 00b$ );
- the timer overflow interrupt is zero, see [Timer Overflow Interrupt](#);
- the channels interrupts are zero, see [Channel \(n\) Interrupt](#);
- the fault interrupt is zero, see [Fault Interrupt](#);
- the channels are in input capture mode, see [Input Capture mode](#);
- the channels outputs are zero;
- the channels pins are not controlled by FTM ( $ELS(n)B:ELS(n)A = 0:0$ ) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

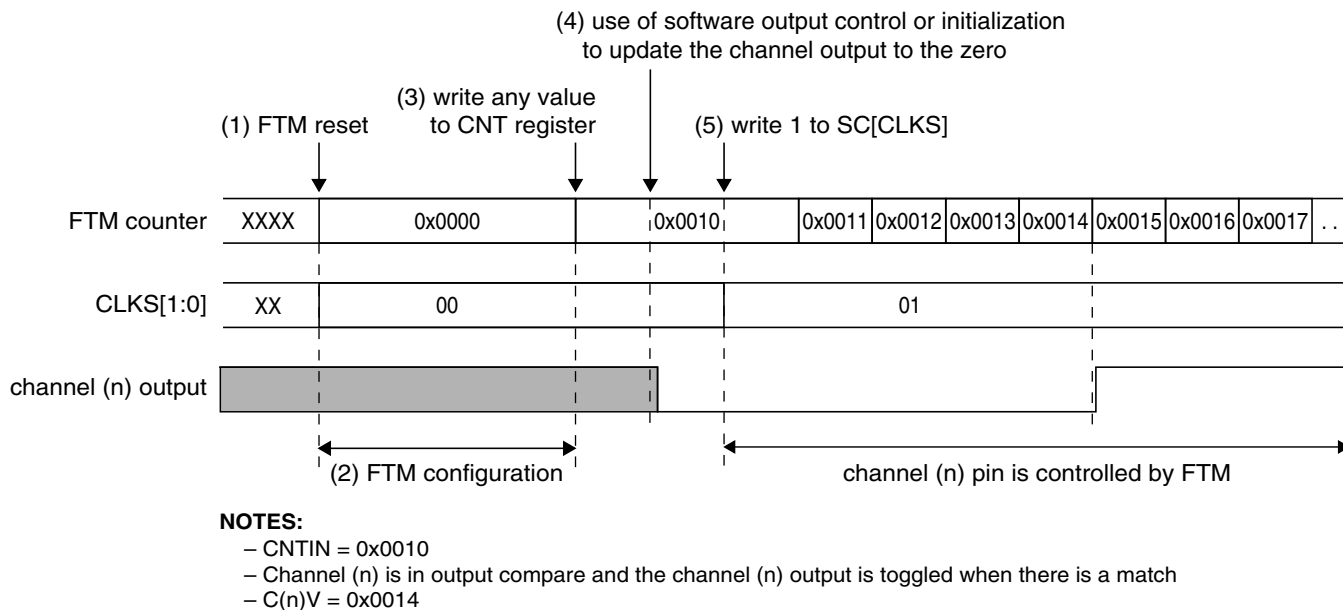

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

**Figure 42-300. FTM behavior after reset when the channel (n) is in Combine mode**

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software output control](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

**Figure 42-301. FTM behavior after reset when the channel (n) is in Output Compare mode**

## 42.6 FTM Interrupts

### 42.6.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 42.6.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

### 42.6.3 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

## 42.7 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:
  - Write to MOD.
  - Write to CNTIN.
  - Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
  - Select the high-true and low-true channels modes.
  - Write to CnV for all channels that will be used .
  - (Re)Configure deadtime and fault control.
  - Do not use the SWOC without SW synchronization (see item 6).
  - Do not use the Inverting without SW synchronization (see item 6).
  - Do not use the Initialization.
  - Do not change the polarity control.
  - Do not configure the HW synchronization

- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.
- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
  - Write to SYNCONF.
    - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
    - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
    - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
    - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2'b00): SWWRBUF = 0 and CNTINC = 0 .
    - SW Synchronization for counter reset (always): SWRSTCNT = 1.
    - Enhanced synchronization (always): SYNCMODE = 1
  - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
  - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
  - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

## Chapter 43

# Periodic Interrupt Timer (PIT)

### 43.1 Introduction

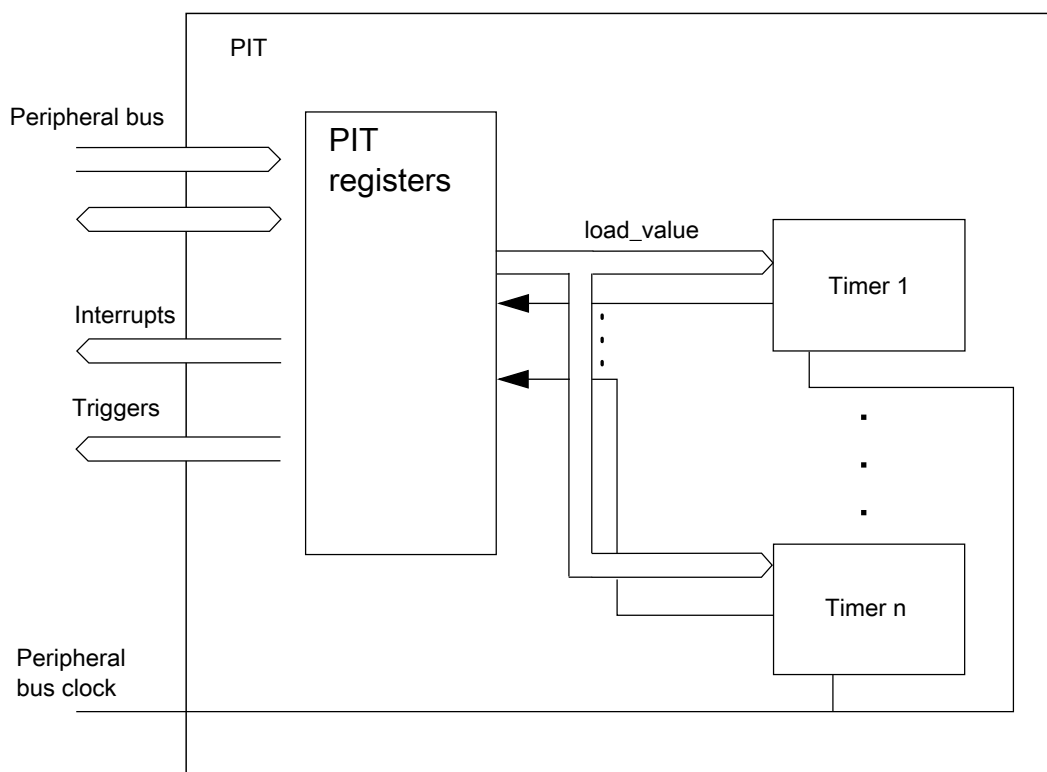

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

#### 43.1.1 Block diagram

The following figure shows the block diagram of the PIT module.

**Figure 43-1. Block diagram of the PIT**

**NOTE**

See the chip-specific PIT information for the number of PIT channels used in this MCU.

### 43.1.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

## 43.2 Signal description

The PIT module has no external pins.

## 43.3 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

### PIT memory map

| Absolute address (hex) | Register name                            | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|--|-----------------|--------|-------------|-----------------------------|

### 43.3.1 PIT Module Control Register (PIT\_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

**memory map/register description**

Address: 4003\_7000h base + 0h offset = 4003\_7000h

**PIT\_MCR field descriptions**

| Field            | Description   |
|------------------|---|
| 31–3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>Reserved    | This field is reserved.   |
| 1<br>MDIS        | Module Disable - (PIT section)<br>Disables the standard timers. This field must be enabled before any other setup is done.<br>0 Clock for standard PIT timers is enabled.<br>1 Clock for standard PIT timers is disabled. |
| 0<br>FRZ         | Freeze<br>Allows the timers to be stopped when the device enters the Debug mode.<br>0 Timers continue to run in Debug mode.<br>1 Timers are stopped in Debug mode.  |

### 43.3.2 Timer Load Value Register (PIT\_LDVALn)

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 4003\_7000h base + 100h offset + (16d × i), where i=0d to 3d

#### PIT\_LDVALn field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>TSV | <p>Timer Start Value</p> <p>Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.</p> |

### 43.3.3 Current Timer Value Register (PIT\_CVALn)

These registers indicate the current timer position.

Access: User read only

Address: 4003\_7000h base + 104h offset + (16d × i), where i=0d to 3d

#### PIT\_CVALn field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>TVL | <p>Current Timer Value</p> <p>Represents the current timer value, if the timer is enabled.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>If the timer is disabled, do not use this field as its value is unreliable.</li> <li>The timer uses a downcounter. The timer values are frozen in Debug mode if MCR[FRZ] is set.</li> </ul> |

### 43.3.4 Timer Control Register (PIT\_TCTRLn)

These registers contain the control bits for each timer.

Access: User read/write

Address: 4003\_7000h base + 108h offset + (16d × i), where i=0d to 3d

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |     |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18  | 17  | 16  |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |     |     |     |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |     |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   | 0   | 0   |
| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2   | 1   | 0   |

| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |     |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0   | 0   | 0   |

#### PIT\_TCTRLn field descriptions

| Field            | Description   |
|------------------|---|
| 31–3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>CHN         | Chain Mode<br>When activated, Timer n-1 needs to expire before timer n can decrement by 1.<br>Timer 0 cannot be chained.<br>0 Timer is not chained.<br>1 Timer is chained to previous timer. For example, for Channel 2, if this field is set, Timer 2 is chained to Timer 1.   |
| 1<br>TIE         | Timer Interrupt Enable<br>When an interrupt is pending, or, TFLGn[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first.<br>0 Interrupt requests from Timer n are disabled.<br>1 Interrupt will be requested whenever TIF is set. |
| 0<br>TEN         | Timer Enable<br>Enables or disables the timer.<br>0 Timer n is disabled.<br>1 Timer n is enabled.   |

### 43.3.5 Timer Flag Register (PIT\_TFLGn)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 4003\_7000h base + 10Ch offset + (16d × i), where i=0d to 3d

|       |    |    |    |    |    |    |    |    |  |    |    |    |    |    |    |     |    |
|-------|----|----|----|----|----|----|----|----|--|----|----|----|----|----|----|-----|----|

| 0<br>TIF         | Timer Interrupt Flag<br><br>Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request.<br><br>0 Timeout has not yet occurred.<br>1 Timeout has occurred. |

## 43.4 Functional description

This section provides the functional description of the module.

### 43.4.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

#### 43.4.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

**Figure 43-23. Stopping and starting a timer**

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

**Figure 43-24. Modifying running timer period**

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

**Figure 43-25. Dynamically setting a new load value**

### 43.4.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

### 43.4.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

### 43.4.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

## 43.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every  $5.12 \text{ ms} / 20 \text{ ns} = 256,000$  cycles and Timer 3 every  $30 \text{ ms} / 20 \text{ ns} = 1,500,000$  cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) - 1

#### example configuration for chained timers

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

## 43.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

# Chapter 44

## Low-Power Timer (LPTMR)

### 44.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

#### 44.1.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

#### 44.1.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

**Table 44-1. Modes of operation**

| Modes       | Description  |
|-------------|--|
| Run         | The LPTMR operates normally.   |
| Wait        | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Stop        | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Low-Leakage | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Debug       | The LPTMR operates normally.   |

## 44.2 LPTMR signal descriptions

**Table 44-2. LPTMR signal descriptions**

| Signal             | I/O | Description             |
|--------------------|-----|-------------------------|
| LPTMR_ALT <i>n</i> | I   | Pulse Counter Input pin |

### 44.2.1 Detailed signal descriptions

**Table 44-3. LPTMR interface—detailed signal descriptions**

| Signal             | I/O | Description  |
|--------------------|-----|--|
| LPTMR_ALT <i>n</i> | I   | Pulse Counter Input<br>The LPTMR can select one of the input pins to be used in Pulse Counter mode.  |
|                    |     | State meaning<br>Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment.<br>Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment. |
|                    |     | Timing<br>Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.  |

## 44.3 Memory map and register definition

### NOTE

The LPTMR registers are reset only on a POR or LVD event.  
See [LPTMR power and reset](#) for more details.

#### LPTMR memory map

| Absolute address (hex) | Register name  | Width (in bits) | Access | Reset value | Section/page                |

## 44.4 Functional description

### 44.4.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

### 44.4.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

**NOTE**

The clock source selected need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

#### NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency  $f_{LPTMR}$  defined in the device datasheet.

### 44.4.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

#### NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

#### 44.4.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every  $2^2$  to  $2^{16}$  prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

#### 44.4.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

### 44.4.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

| If   | Then   |
|--|--|
| The selected input source remains deasserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising edges | The glitch filter output will also deassert. |
| The selected input source remains asserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising-edges   | The glitch filter output will also assert.   |

#### NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every  $2^2$  to  $2^{16}$  prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

### 44.4.3.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

## 44.4.4 LPTMR compare

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

### 44.4.5 LPTMR counter

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

### 44.4.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

| When  | Then   |
|---|--|
| The CMR is set to 0 with CSR[TFC] clear                   | The LPTMR hardware trigger will assert on the first compare and does not deassert.                         |
| The CMR is set to a nonzero value, or, if CSR[TFC] is set | The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR. |

### 44.4.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

# Chapter 45

## Carrier Modulator Transmitter (CMT)

### 45.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The carrier modulator transmitter (CMT) module provides the means to generate the protocol timing and carrier signals for a wide variety of encoding schemes. The CMT incorporates hardware to off-load the critical and/or lengthy timing requirements associated with signal generation from the CPU, releasing much of its bandwidth to handle other tasks such as:

- Code data generation
- Data decompression, or,
- Keyboard scanning

. The CMT does not include dedicated hardware configurations for specific protocols, but is intended to be sufficiently programmable in its function to handle the timing requirements of most protocols with minimal CPU intervention.

When the modulator is disabled, certain CMT registers can be used to change the state of the infrared output (IRO) signal directly. This feature allows for the generation of future protocol timing signals not readily producible by the current architecture.

### 45.2 Features

The features of this module include:

- Four modes of operation:
  - Time; with independent control of high and low times

**Block diagram**

- Baseband
- Frequency-shift key (FSK)
- Direct software control of the IRO signal
- Extended space operation in Time, Baseband, and FSK modes
- Selectable input clock divider
- Interrupt on end-of-cycle
  - Ability to disable the IRO signal and use as timer interrupt

### 45.3 Block diagram

The following figure presents the block diagram of the CMT module.

Figure 45-1. CMT module block diagram

### 45.4 Modes of operation

The following table describes the operation of the CMT module operates in various modes.

Table 45-1. Modes of operation

| Modes    | Description  |
|----------|--|
| Time     | In Time mode, the user independently defines the high and low times of the carrier signal to determine both period and duty cycle                    |
| Baseband | When MSC[BASE] is set, the carrier output ( $f_{cg}$ ) to the modulator is held high continuously to allow for the generation of baseband protocols. |

Table continues on the next page...

**Table 45-1. Modes of operation (continued)**

| Modes               | Description  |
|---------------------|--|
| Frequency-shift key | This mode allows the carrier generator to alternate between two sets of high and low times. When operating in FSK mode, the generator will toggle between the two sets when instructed by the modulator, allowing the user to dynamically switch between two carrier frequencies without CPU intervention. |

The following table summarizes the modes of operation of the CMT module.

**Table 45-2. CMT modes of operation**

| Mode           | MSC[MCGEN] <sup>1</sup> | MSC[BASE] <sup>2</sup> | MSC[FSK] <sup>2</sup> | MSC[EXSPC] | Comment   |
|----------------|-------------------------|------------------------|-----------------------|------------|---|
| Time           | 1                       | 0                      | 0                     | 0          | $f_{cg}$ controlled by primary high and low registers.<br>$f_{cg}$ transmitted to the IRO signal when modulator gate is open.   |
| Baseband       | 1                       | 1                      | X                     | 0          | $f_{cg}$ is always high. The IRO signal is high when the modulator gate is open.  |
| FSK            | 1                       | 0                      | 1                     | 0          | $f_{cg}$ control alternates between primary high/low registers and secondary high/low registers.<br>$f_{cg}$ transmitted to the IRO signal when modulator gate is open. |
| Extended Space | 1                       | X                      | X                     | 1          | Setting MSC[EXSPC] causes subsequent modulator cycles to be spaces (modulator out not asserted) for the duration of the modulator period (mark and space times).        |
| IRO Latch      | 0                       | X                      | X                     | X          | OC[IROL] controls the state of the IRO signal.  |

1. To prevent spurious operation, initialize all data and control registers before beginning a transmission when MSC[MCGEN]=1.
2. This field is not double-buffered and must not be changed during a transmission while MSC[MCGEN]=1.

**NOTE**

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

### 45.4.1 Wait mode operation

During Wait mode, the CMT if enabled, will continue to operate normally. However, there is no change in operating modes of CMT during Wait mode, because the CPU is not operating.

## 45.4.2 Stop mode operation

This section describes the CMT Stop mode operations.

### 45.4.2.1 Normal Stop mode operation

During Normal Stop mode, clocks to the CMT module are halted. No registers are affected.

The CMT module will resume upon exit from Normal Stop mode because the clocks are halted. Software must ensure that the Normal Stop mode is not entered while the modulator is still in operation so as to prevent the IRO signal from being asserted while in Normal Stop mode. This may require a timeout period from the time that MSC[MCGEN] is cleared to allow the last modulator cycle to complete.

### 45.4.2.2 Low-Power Stop mode operation

During Low-Power Stop mode, the CMT module is completely powered off internally and the IRO signal state is latched and held at the time when the CMT enters this mode. To prevent the IRO signal from being asserted during Low-Power Stop mode, the software must assure that the signal is not active when entering Low-Power Stop mode. Upon wakeup from Low-Power Stop mode, the CMT module will be in the reset state.

## 45.5 CMT external signal descriptions

The following table shows the description of the external signal.

**Table 45-3. CMT signal description**

| Signal  | Description     | I/O |
|---------|-----------------|-----|
| CMT_IRO | Infrared Output | O   |

## 45.5.1 CMT\_IRO — Infrared Output

This output signal is driven by the modulator output when MSC[MCGEN] and OC[IROPEN] are set. The IRO signal starts a valid transmission with a delay, after MSC[MCGEN] bit be asserted to high, that can be calculated based on two register bits. [Table 45-5](#) shows how to calculate this delay.

The following table describes conditions for the IRO signal to be active.

| If  | Then   |
|---|--|
| MSC[MCGEN] is cleared and OC[IROPEN] is set | The signal is driven by OC[IROL] . This enables user software to directly control the state of the IRO signal by writing to OC[IROL] .   |
| OC[IROPEN] is cleared                       | The signal is disabled and is not driven by the CMT module. Therefore, CMT can be configured as a modulo timer for generating periodic interrupts without causing signal activity. |

**Table 45-5. CMT\_IRO signal delay calculation**

| Condition       | Delay (bus clock cycles) |
|-----------------|--------------------------|
| MSC[CMTDIV] = 0 | PPS[PPSDIV] + 2          |
| MSC[CMTDIV] > 0 | (PPS[PPSDIV] *2) + 3     |

## 45.6 Memory map/register definition

The following registers control and monitor the CMT operation.

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level. The address offset is defined at the module level.

**CMT memory map**

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value | Section/ page               |
|------------------------|---|-----------------|--------|-------------|-----------------------------|
| 4006_2000              | CMT Carrier Generator High Data Register 1 (CMT_CGH1) | 8               | R/W    | Undefined   | <a href="#">45.6.1/1253</a> |

## 45.6.1 CMT Carrier Generator High Data Register 1 (CMT\_CGH1)

This data register contains the primary high value for generating the carrier output.

Address: 4006\_2000h base + 0h offset = 4006\_2000h

|       |    |    |    |    |    |    |    |    |
|-------|----|----|----|----|----|----|----|----|
| Bit   | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | PH |    |    |    |    |    |    |    |
| Write | PH |    |    |    |    |    |    |    |
| Reset | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### CMT\_CGH1 field descriptions

| Field     | Description   |
|-----------|---|
| 7–0<br>PH | <p>Primary Carrier High Time Data Value</p> <p>Contains the number of input clocks required to generate the carrier high time period. When operating in Time mode, this register is always selected. When operating in FSK mode, this register and the secondary register pair are alternately selected under the control of the modulator. The primary carrier high time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled to avoid spurious results.</p> |

## 45.6.2 CMT Carrier Generator Low Data Register 1 (CMT\_CGL1)

This data register contains the primary low value for generating the carrier output.

Address: 4006\_2000h base + 1h offset = 4006\_2001h

|       |    |    |    |    |    |    |    |    |
|-------|----|----|----|----|----|----|----|----|
| Bit   | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | PL |    |    |    |    |    |    |    |
| Write |    |    |    |    |    |    |    |    |
| Reset | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### CMT\_CGL1 field descriptions

| Field     | Description  |
|-----------|--|
| 7-0<br>PL | <p>Primary Carrier Low Time Data Value</p> <p>Contains the number of input clocks required to generate the carrier low time period. When operating in Time mode, this register is always selected. When operating in FSK mode, this register and the secondary register pair are alternately selected under the control of the modulator. The primary carrier low time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled to avoid spurious results.</p> |

## 45.6.3 CMT Carrier Generator High Data Register 2 (CMT\_CGH2)

This data register contains the secondary high value for generating the carrier output.

Address: 4006\_2000h base + 2h offset = 4006\_2002h

|       |    |    |    |    |    |    |    |    |
|-------|----|----|----|----|----|----|----|----|
| Bit   | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | SH |    |    |    |    |    |    |    |
| Write |    |    |    |    |    |    |    |    |
| Reset | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### CMT\_CGH2 field descriptions

| Field     | Description  |
|-----------|--|
| 7-0<br>SH | <p>Secondary Carrier High Time Data Value</p> <p>Contains the number of input clocks required to generate the carrier high time period. When operating in Time mode, this register is never selected. When operating in FSK mode, this register and the primary register pair are alternately selected under control of the modulator.</p> |

**CMT\_CGH2 field descriptions (continued)**

| Field | Description  |
|-------|--|
|       | The secondary carrier high time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled when operating in FSK mode. |

**45.6.4 CMT Carrier Generator Low Data Register 2 (CMT\_CGL2)**

This data register contains the secondary low value for generating the carrier output.

Address: 4006\_2000h base + 3h offset = 4006\_2003h

|       |    |    |    |    |    |    |    |    |
|-------|----|----|----|----|----|----|----|----|
| Bit   | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Read  | SL |    |    |    |    |    |    |    |
| Write | SL |    |    |    |    |    |    |    |
| Reset | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

**CMT\_CGL2 field descriptions**

| Field     | Description  |
|-----------|--|
| 7-0<br>SL | <p>Secondary Carrier Low Time Data Value</p> <p>Contains the number of input clocks required to generate the carrier low time period. When operating in Time mode, this register is never selected. When operating in FSK mode, this register and the primary register pair are alternately selected under the control of the modulator. The secondary carrier low time value is undefined out of reset. This register must be written to nonzero values before the carrier generator is enabled when operating in FSK mode.</p> |

**45.6.5 CMT Output Control Register (CMT\_OC)**

This register is used to control the IRO signal of the CMT module.

Address: 4006\_2000h base + 4h offset = 4006\_2004h

|       |      |       |        |   |   |   |   |   |
|-------|------|-------|--------|---|---|---|---|---|
| Bit   | 7    | 6     | 5      | 4 | 3 | 2 | 1 | 0 |
| Read  | IROL | CMPOL | IROPEN | 0 |   |   |   |   |
| Write | IROL | CMPOL | IROPEN | 0 |   |   |   |   |
| Reset | 0    | 0     | 0      | 0 | 0 | 0 | 0 | 0 |

### CMT\_OC field descriptions

| Field           | Description   |
|-----------------|---|
| 7<br>IROL       | IRO Latch Control<br>Reads the state of the IRO latch. Writing to IROL changes the state of the IRO signal when MSC[MCGEN] is cleared and IROPEN is set.  |
| 6<br>CMTPOL     | CMT Output Polarity<br>Controls the polarity of the IRO signal.<br>0 The IRO signal is active-low.<br>1 The IRO signal is active-high.  |
| 5<br>IROPEN     | IRO Pin Enable<br>Enables and disables the IRO signal. When the IRO signal is enabled, it is an output that drives out either the CMT transmitter output or the state of IROL depending on whether MSC[MCGEN] is set or not. Also, the state of output is either inverted or non-inverted, depending on the state of CMTPOL. When the IRO signal is disabled, it is in a high-impedance state and is unable to draw any current. This signal is disabled during reset.<br>0 The IRO signal is disabled.<br>1 The IRO signal is enabled as output. |
| 4–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

## 45.6.6 CMT Modulator Status and Control Register (CMT\_MSC)

This register contains the modulator and carrier generator enable (MCGEN), end of cycle interrupt enable (EOCIE), FSK mode select (FSK), baseband enable (BASE), extended space (EXSPC), prescaler (CMTDIV) bits, and the end of cycle (EOCF) status bit.

Address: 4006\_2000h base + 5h offset = 4006\_2005h

## 45.7 Functional description

The CMT module primarily consists of clock divider, carrier generator, and modulator.

### 45.7.1 Clock divider

The CMT was originally designed to be based on an 8 MHz bus clock that could be divided by 1, 2, 4, or 8 according to the specification. To be compatible with higher bus frequency, the primary prescaler (PPS) was developed to receive a higher frequency and generate a clock enable signal called intermediate frequency (IF). This IF must be approximately equal to 8 MHz and will work as a clock enable to the secondary prescaler. The following figure shows the clock divider block diagram.

**Figure 45-14. Clock divider block diagram**

For compatibility with previous versions of CMT, when bus clock = 8 MHz, the PPS must be configured to zero. The PPS counter is selected according to the bus clock to generate an intermediate frequency approximately equal to 8 MHz.

### 45.7.2 Carrier generator

The carrier generator resolution is 125 ns when operating with an 8 MHz intermediate frequency signal and the secondary prescaler is set to divide by 1, or, when  $MSC[CMTDIV] = 00$ . The carrier generator can generate signals with periods between 250 ns (4 MHz) and 127.5  $\mu s$  (7.84 kHz) in steps of 125 ns. The following table shows the relationship between the clock divide bits and the carrier generator resolution, minimum carrier generator period, and minimum modulator period.

**Table 45-19. Clock divider**

| Bus clock (MHz) | MSC[CMTDIV] | Carrier generator resolution ( $\mu$ s) | Min. carrier generator period ( $\mu$ s) | Min. modulator period ( $\mu$ s) |
|-----------------|-------------|---|--|----------------------------------|
| 8               | 00          | 0.125                                   | 0.25                                     | 1.0                              |
| 8               | 01          | 0.25                                    | 0.5                                      | 2.0                              |
| 8               | 10          | 0.5                                     | 1.0                                      | 4.0                              |
| 8               | 11          | 1.0                                     | 2.0                                      | 8.0                              |

The possible duty cycle options depend upon the number of counts required to complete the carrier period. For example, 1.6 MHz signal has a period of 625 ns and will therefore require 5 x 125 ns counts to generate. These counts may be split between high and low times, so the duty cycles available will be:

- 20% with one high and four low times
- 40% with two high and three low times
- 60% with three high and two low times, and
- 80% with four high and one low time

For low-frequency signals with large periods, high-resolution duty cycles as a percentage of the total period, are possible.

The carrier signal is generated by counting a register-selected number of input clocks (125 ns for an 8 MHz bus) for both the carrier high time and the carrier low time. The period is determined by the total number of clocks counted. The duty cycle is determined by the ratio of high-time clocks to total clocks counted. The high and low time values are user-programmable and are held in two registers.

An alternate set of high/low count values is held in another set of registers to allow the generation of dual-frequency FSK protocols without CPU intervention.

### Note

Only nonzero data values are allowed. The carrier generator will not work if any of the count values are equal to zero.

MSC[MCGEN] must be set and MSC[BASE] must be cleared to enable carrier generator clocks. When MSC[BASE] is set, the carrier output to the modulator is held high continuously. The following figure represents the block diagram of the clock generator.

**Figure 45-15. Carrier generator block diagram**

The high/low time counter is an 8-bit up counter. After each increment, the contents of the counter are compared with the appropriate high or low count value register. When the compare value is reached, the counter is reset to a value of 0x01, and the compare is redirected to the other count value register.

Assuming that the high time count compare register is currently active, a valid compare will cause the carrier output to be driven low. The counter will continue to increment starting at the reset value of 0x01. When the value stored in the selected low count value register is reached, the counter will again be reset and the carrier output will be driven high.

The cycle repeats, automatically generating a periodic signal which is directed to the modulator. The lower frequency with maximum period,  $f_{\max}$ , and highest frequency with minimum period,  $f_{\min}$ , which can be generated, are defined as:

$$f_{\max} = f_{\text{CMTCLK}} \div (2 * 1) \text{ Hz}$$

$$f_{\min} = f_{\text{CMTCLK}} \div (2 * (2^8 - 1)) \text{ Hz}$$

In the general case, the carrier generator output frequency is:

$$f_{\text{cg}} = f_{\text{CMTCLK}} \div (\text{High count} + \text{Low count}) \text{ Hz}$$

Where:  $0 < \text{High count} < 256$  and

$$0 < \text{Low count} < 256$$

The duty cycle of the carrier signal is controlled by varying the ratio of high time to low + high time. As the input clock period is fixed, the duty cycle resolution will be proportional to the number of counts required to generate the desired carrier period.

$$\text{DutyCycle} = \frac{\text{Highcount}}{\text{Highcount} + \text{Lowcount}}$$

### 45.7.3 Modulator

The modulator block controls the state of the infrared out signal (IRO). The modulator output is gated on to the IRO signal when the modulator/carrier generator is enabled. . When the modulator/carrier generator is disabled, the IRO signal is controlled by the state of the IRO latch. OC[CMTPOL] enables the IRO signal to be active-high or active-low.

The following table describes the functions of the modulators in different modes:

**Table 45-20. Mode functions**

| Mode     | Function   |
|----------|--|
| Time     | The modulator can gate the carrier onto the modulator output.  |
| Baseband | The modulator can control the logic level of the modulator output.   |
| FSK      | The modulator can count carrier periods and instruct the carrier generator to alternate between two carrier frequencies whenever a modulation period consisting of mark and space counts, expires. |

The modulator provides a simple method to control protocol timing. The modulator has a minimum resolution of 1.0  $\mu\text{s}$  with an 8 MHz. It can count bus clocks to provide real-time control, or carrier clocks for self-clocked protocols.

The modulator includes a 17-bit down counter with underflow detection. The counter is loaded from the 16-bit modulation mark period buffer registers, CMD1 and CMD2. The most significant bit is loaded with a logic 0 and serves as a sign bit.

| When                               | Then  |
|------------------------------------|---|
| The counter holds a positive value | The modulator gate is open and the carrier signal is driven to the transmitter block.   |
| The counter underflows             | The modulator gate is closed and a 16-bit comparator is enabled which compares the logical complement of the value of the down counter with the contents of the modulation space period register which has been loaded from the registers, CMD3 and CMD4. |

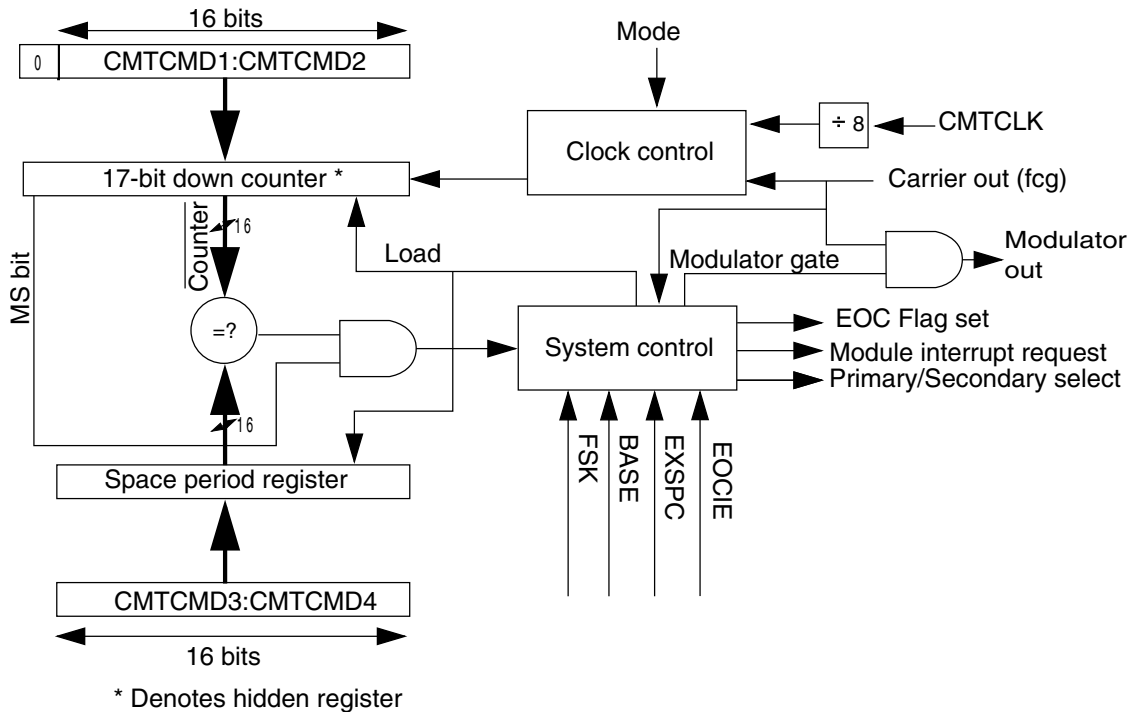

When a match is obtained, the cycle repeats by opening the modulator gate, reloading the counter with the contents of CMD1 and CMD2, and reloading the modulation space period register with the contents of CMD3 and CMD4.

The modulation space period is activated when the carrier signal is low to prohibit cutting off the high pulse of a carrier signal. If the carrier signal is high, the modulator extends the mark period until the carrier signal becomes low. To deassert the space period and assert the mark period, the carrier signal must have gone low to ensure that a space period is not erroneously shortened.

If the contents of the modulation space period register are all zeroes, the match will be immediate and no space period will be generated, for instance, for FSK protocols that require successive bursts of different frequencies).

MSC[MCGEN] must be set to enable the modulator timer.

The following figure presents the block diagram of the modulator.

**Figure 45-16. Modulator block diagram**

### 45.7.3.1 Time mode

When the modulator operates in Time mode, or, when MSC[MCGEN] is set, and MSC[BASE] and MSC[FSK] are cleared:

- The modulation mark period consists of an integer number of  $(\text{CMTCLK} \div 8)$  clock periods.
- The modulation space period consists of 0 or an integer number of  $(\text{CMTCLK} \div 8)$  clock periods.

With an 8 MHz IF and  $\text{MSC}[\text{CMTDIV}] = 00$ , the modulator resolution is 1  $\mu\text{s}$  and has a maximum mark and space period of about 65.535  $\mu\text{s}$  each. See [Figure 45-17](#) for an example of the Time and Baseband mode outputs.

The mark and space time equations for Time and Baseband mode are:

$$t_{\text{mark}} = (\text{CMD1}:\text{CMD2} + 1) \div (f_{\text{CMTCLK}} \div 8)$$

$$t_{\text{space}} = \text{CMD3}:\text{CMD4} \div (f_{\text{CMTCLK}} \div 8)$$

where  $\text{CMD1}:\text{CMD2}$  and  $\text{CMD3}:\text{CMD4}$  are the decimal values of the concatenated registers.

**Figure 45-17. Example: CMT output in Time and Baseband modes with  $\text{OC}[\text{CMTPOL}] = 0$**

### 45.7.3.2 Baseband mode

Baseband mode, that is, when  $\text{MSC}[\text{MCGEN}]$  and  $\text{MSC}[\text{BASE}]$  are set, is a derivative of Time mode, where the mark and space period is based on  $(\text{CMTCLK} \div 8)$  counts. The mark and space calculations are the same as in Time mode.

In this mode, the modulator output will be at a logic 1 for the duration of the mark period and at a logic 0 for the duration of a space period. See [Figure 45-17](#) for an example of the output for both Baseband and Time modes. In the example, the carrier out frequency ( $f_{cg}$ ) is generated with a high count of 0x01 and a low count of 0x02 that results in a divide of 3 of CMTCLK with a 33% duty cycle. The modulator down counter was loaded with the value 0x0003 and the space period register with 0x0002.

### Note

The waveforms in [Figure 45-17](#) and [Figure 45-18](#) are for the purpose of conceptual illustration and are not meant to represent precise timing relationships between the signals shown.

### 45.7.3.3 FSK mode

When the modulator operates in FSK mode, that is, when MSC[MCGEN] and MSC[FSK] are set, and MSC[BASE] is cleared:

- The modulation mark and space periods consist of an integer number of carrier clocks (space period can be zero).
- When the mark period expires, the space period is transparently started as in Time mode.
- The carrier generator toggles between primary and secondary data register values whenever the modulator space period expires.

The space period provides an interpulse gap (no carrier). If CMD3:CMD4 = 0x0000, then the modulator and carrier generator will switch between carrier frequencies without a gap or any carrier glitches (zero space).

Using timing data for carrier burst and interpulse gap length calculated by the CPU, FSK mode can automatically generate a phase-coherent, dual-frequency FSK signal with programmable burst and interburst gaps.

The mark and space time equations for FSK mode are:

$$t_{\text{mark}} = (\text{CMD1:CMD2} + 1) \div f_{cg}$$

$$t_{\text{space}} = (\text{CMD3:CMD4}) \div f_{cg}$$

Where  $f_{cg}$  is the frequency output from the carrier generator. The example in [Figure 45-18](#) shows what the IRO signal looks like in FSK mode with the following values:

- CMD1:CMD2 = 0x0003
- CMD3:CMD4 = 0x0002
- Primary carrier high count = 0x01
- Primary carrier low count = 0x02

- Secondary carrier high count = 0x03
- Secondary carrier low count = 0x01

**Figure 45-18. Example: CMT output in FSK mode**

## 45.7.4 Extended space operation

In either Time, Baseband, or FSK mode, the space period can be made longer than the maximum possible value of the space period register. Setting MSC[EXSPC] will force the modulator to treat the next modulation period beginning with the next load of the counter and space period register, as a space period equal in length to the mark and space counts combined. Subsequent modulation periods will consist entirely of these extended space periods with no mark periods. Clearing MSC[EXSPC] will return the modulator to standard operation at the beginning of the next modulation period.

### 45.7.4.1 EXSPC operation in Time mode

To calculate the length of an extended space in Time or Baseband mode, add the mark and space times and multiply by the number of modulation periods when MSC[EXSPC] is set.

$$t_{\text{exspace}} = (t_{\text{mark}} + t_{\text{space}}) * (\text{number of modulation periods})$$

For an example of extended space operation, see [Figure 45-19](#).

#### Note

The extended space enable feature can be used to emulate a zero mark event.

**Figure 45-19. Extended space operation**

### 45.7.4.2 EXSPC operation in FSK mode

In FSK mode, the modulator continues to count carrier out clocks, alternating between the primary and secondary registers at the end of each modulation period.

To calculate the length of an extended space in FSK mode, it is required to know whether MSC[EXSPC] was set on a primary or secondary modulation period, and the total number of both primary and secondary modulation periods completed while MSC[EXSPC] is high. A status bit for the current modulation is not accessible to the CPU. If necessary, software must maintain tracking of the current primary or secondary modulation cycle. The extended space period ends at the completion of the space period time of the modulation period during which MSC[EXSPC] is cleared.

The following table depicts the equations which can be used to calculate the extended space period depending on when MSC[EXSPC] is set.

| If   | Then   |
|--|--|
| MSC[EXSPC] was set during a primary modulation cycle       | Use the equation:<br>$t_{\text{exspace}} = (t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + \dots$ |
| MSC[EXSPC] bit was set during a secondary modulation cycle | Use the equation:<br>$t_{\text{exspace}} = (t_{\text{space}})_s + (t_{\text{mark}} + t_{\text{space}})_p + (t_{\text{mark}} + t_{\text{space}})_s + \dots$ |

Where the subscripts p and s refer to mark and space times for the primary and secondary modulation cycles.

## 45.8 CMT interrupts and DMA

The CMT generates an interrupt request or a DMA transfer request according to MSC[EOCIE], MSC[EOCF], DMA[DMA] bits.

**Table 45-23. DMA transfer request x CMT interrupt request**

| MSC[EOCF] | DMA[DMA] | MSC[EOCIE] | DMA transfer request | CMT interrupt request |
|-----------|----------|------------|----------------------|-----------------------|
| 0         | X        | X          | 0                    | 0                     |
| 1         | X        | 0          | 0                    | 0                     |
| 1         | 0        | 1          | 0                    | 1                     |
| 1         | 1        | 1          | 1                    | 0                     |

MSC[EOCF] is set:

- When the modulator is not currently active and MSC[MCGEN] is set to begin the initial CMT transmission.
- At the end of each modulation cycle when the counter is reloaded from CMD1:CMD2, while MSC[MCGEN] is set.

When MSC[MCGEN] is cleared and then set before the end of the modulation cycle, MSC[EOCF] will not be set when MSC[MCGEN] is set, but will become set at the end of the current modulation cycle.

When MSC[MCGEN] becomes disabled, the CMT module does not set MSC[EOCF] at the end of the last modulation cycle.

If MSC[EOCIE] is high when MSC[EOCF] is set, the CMT module will generate an interrupt request or a DMA transfer request.

MSC[EOCF] must be cleared to prevent from being generated by another event like interrupt or DMA request, after exiting the service routine. See the following table.

**Table 45-24. How to clear MSC[EOCF]**

| DMA[DMA] | MSC[EOCIE] | Description  |
|----------|------------|--|
| 0        | X          | MSC[EOCF] is cleared by reading MSC followed by an access of CMD2 or CMD4. |
| 1        | X          | MSC[EOCF] is cleared by the CMT DMA transfer done.                         |

The EOC interrupt is coincident with:

- Loading the down-counter with the contents of CMD1:CMD2
- Loading the space period register with the contents of CMD3:CMD4

The EOC interrupt provides a means for the user to reload new mark/space values into the modulator data registers. Modulator data register updates will take effect at the end of the current modulation cycle.

#### **NOTE**

The down-counter and space period register are updated at the end of every modulation cycle, irrespective of interrupt handling and the state of MSC[EOCF].

# Chapter 46

## Real Time Clock (RTC)

### 46.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

#### 46.1.1 Features

The RTC module features include:

- Independent power supply, POR, and 32 kHz crystal oscillator
- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Register write protection
  - Lock register requires VBAT POR or software reset to enable write access
  - Access control registers require system reset to enable read and/or write access
- 1 Hz square wave output with optional interrupt
- 64-bit monotonic counter with roll-over protection
- Tamper time seconds register that records when the time was invalidated

## 46.1.2 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode. It operates in one of two modes of operation: chip power-up and chip power-down.

During chip power-down, RTC is powered from the backup power supply (VBAT) and is electrically isolated from the rest of the chip but continues to increment the time counter (if enabled) and retain the state of the RTC registers. The RTC registers are not accessible.

During chip power-up, RTC remains powered from the backup power supply (VBAT). All RTC registers are accessible by software and all functions are operational. If enabled, the 32.768 kHz clock can be supplied to the rest of the chip.

## 46.1.3 RTC signal descriptions

Table 46-1. RTC signal descriptions

| Signal     | Description                         | I/O |
|------------|-------------------------------------|-----|
| EXTAL32    | 32.768 kHz oscillator input         | I   |
| XTAL32     | 32.768 kHz oscillator output        | O   |
| RTC_CLKOUT | 1 Hz square-wave output or OSCERCLK | O   |
| RTC_WAKEUP | Wakeup for external device          | I/O |

### 46.1.3.1 RTC clock output

The clock to the seconds counter is available on the RTC\_CLKOUT signal. It is a 1 Hz square wave output. See [RTC\\_CLKOUT options](#) for details.

### 46.1.3.2 RTC wakeup pin

The RTC wakeup pin is an open drain, active low, output that allows the RTC to wakeup the chip via an external component. The wakeup pin asserts when the wakeup pin enable is set and either the RTC interrupt is asserted or the wakeup pin is turned on via a register bit. The wakeup pin does not assert from the RTC seconds interrupt.

#### NOTE

The wakeup pin is optional and may not be implemented on all devices.

## 46.2 Register definition

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

Write accesses to any register and read accesses to tamper and monotonic registers by non-supervisor mode software, when the supervisor access bit in the control register is clear, will terminate with a bus error.

Read accesses to other registers by non-supervisor mode software complete as normal.

Writing to a register protected by the write access register or lock register does not generate a bus error, but the write will not complete.

Reading a register protected by the read access register does not generate a bus error, but the register will read zero.

**RTC memory map**

| Absolute address (hex) | Register name                                  | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|--|-----------------|--------|-------------|------------------------------|
| 4003_D000              | RTC Time Seconds Register (RTC_TSR)            | 32              | R/W    | 0000_0000h  | <a href="#">46.2.1/1276</a>  |
| 4003_D004              | RTC Time Prescaler Register (RTC_TPR)          | 32              | R/W    | 0000_0000h  | <a href="#">46.2.2/1276</a>  |
| 4003_D008              | RTC Time Alarm Register (RTC_TAR)              | 32              | R/W    | 0000_0000h  | <a href="#">46.2.3/1277</a>  |
| 4003_D00C              | RTC Time Compensation Register (RTC_TCR)       | 32              | R/W    | 0000_0000h  | <a href="#">46.2.4/1277</a>  |
| 4003_D010              | RTC Control Register (RTC_CR)                  | 32              | R/W    | 0000_0000h  | <a href="#">46.2.5/1278</a>  |

| 4003_D800              | RTC Write Access Register (RTC_WAR)            | 32              | R/W    | 0000_FFFFh  | <a href="#">46.2.13/1287</a> |
| 4003_D804              | RTC Read Access Register (RTC_RAR)             | 32              | R/W    | 0000_FFFFh  | <a href="#">46.2.14/1289</a> |

## 46.2.1 RTC Time Seconds Register (RTC\_TSR)

Address: 4003\_D000h base + 0h offset = 4003\_D000h

### RTC\_TSR field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>TSR | Time Seconds Register<br><br>When the time counter is enabled, the TSR is read only and increments once a second provided SR[TOF] or SR[TIF] are not set. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TSR can be read or written. Writing to the TSR when the time counter is disabled will clear the SR[TOF] and/or the SR[TIF]. Writing to TSR with zero is supported, but not recommended because TSR will read as zero when SR[TIF] or SR[TOF] are set (indicating the time is invalid). |

## 46.2.2 RTC Time Prescaler Register (RTC\_TPR)

Address: 4003\_D000h base + 4h offset = 4003\_D004h

### RTC\_TPR field descriptions

| Field             | Description  |
|-------------------|--|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 15–0<br>TPR       | Time Prescaler Register<br><br>When the time counter is enabled, the TPR is read only and increments every 32.768 kHz clock cycle. The time counter will read as zero when SR[TOF] or SR[TIF] are set. When the time counter is disabled, the TPR can be read or written. The TSR[TSR] increments when bit 14 of the TPR transitions from a logic one to a logic zero. |

### 46.2.3 RTC Time Alarm Register (RTC\_TAR)

Address: 4003\_D000h base + 8h offset = 4003\_D008h

#### RTC\_TAR field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>TAR | Time Alarm Register<br><br>When the time counter is enabled, the SR[TAF] is set whenever the TAR[TAR] equals the TSR[TSR] and the TSR[TSR] increments. Writing to the TAR clears the SR[TAF]. |

### 46.2.4 RTC Time Compensation Register (RTC\_TCR)

Address: 4003\_D000h base + Ch offset = 4003\_D00Ch

#### RTC\_TCR field descriptions

| Field        | Description   |
|--------------|---|
| 31–24<br>CIC | Compensation Interval Counter<br><br>Current value of the compensation interval counter. If the compensation interval counter equals zero then it is loaded with the contents of the CIR. If the CIC does not equal zero then it is decremented once a second.  |
| 23–16<br>TCV | Time Compensation Value<br><br>Current value used by the compensation logic for the present second interval. Updated once a second if the CIC equals 0 with the contents of the TCR field. If the CIC does not equal zero then it is loaded with zero (compensation is not enabled for that second increment).  |
| 15–8<br>CIR  | Compensation Interval Register<br><br>Configures the compensation interval in seconds from 1 to 256 to control how frequently the TCR should adjust the number of 32.768 kHz cycles in each second. The value written should be one less than the number of seconds. For example, write zero to configure for a compensation interval of one second. This register is double buffered and writes do not take affect until the end of the current compensation interval. |
| 7–0<br>TCR   | Time Compensation Register<br><br>Configures the number of 32.768 kHz clock cycles in each second. This register is double buffered and writes do not take affect until the end of the current compensation interval.   |

Table continues on the next page...

### RTC\_TCR field descriptions (continued)

| Field | Description   |
|-------|---|
| 80h   | Time Prescaler Register overflows every 32896 clock cycles. |
| ...   | ...   |
| FFh   | Time Prescaler Register overflows every 32769 clock cycles. |
| 00h   | Time Prescaler Register overflows every 32768 clock cycles. |
| 01h   | Time Prescaler Register overflows every 32767 clock cycles. |
| ...   | ...   |
| 7Fh   | Time Prescaler Register overflows every 32641 clock cycles. |

## 46.2.5 RTC Control Register (RTC\_CR)

Address: 4003\_D000h base + 10h offset = 4003\_D010h

### RTC\_CR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–24<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

Table continues on the next page...

**RTC\_CR field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
| 23–15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 14<br>Reserved    | This field is reserved.<br>It must always be written to 0.  |
| 13<br>SC2P        | Oscillator 2pF Load Configure<br>0 Disable the load.<br>1 Enable the additional load.   |
| 12<br>SC4P        | Oscillator 4pF Load Configure<br>0 Disable the load.<br>1 Enable the additional load.   |
| 11<br>SC8P        | Oscillator 8pF Load Configure<br>0 Disable the load.<br>1 Enable the additional load.   |
| 10<br>SC16P       | Oscillator 16pF Load Configure<br>0 Disable the load.<br>1 Enable the additional load.  |
| 9<br>CLKO         | Clock Output<br>0 The 32 kHz clock is output to other peripherals.<br>1 The 32 kHz clock is not output to other peripherals.  |
| 8<br>OSCE         | Oscillator Enable<br>0 32.768 kHz oscillator is disabled.<br>1 32.768 kHz oscillator is enabled. After setting this bit, wait the oscillator startup time before enabling the time counter to allow the 32.768 kHz clock time to stabilize.   |
| 7–5<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 4<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3<br>UM           | Update Mode<br>Allows SR[TCE] to be written even when the Status Register is locked. When set, the SR[TCE] can always be written if the SR[TIF] or SR[TOF] are set or if the SR[TCE] is clear.<br>Allows the monotonic enable register to be written when it is locked. When set, the monotonic enable register can always be written if the SR[TIF] or SR[MOF] are set or if the montonic counter enable is clear.<br>0 Registers cannot be written when locked.<br>1 Registers can be written when locked under limited conditions. |
| 2<br>SUP          | Supervisor Access<br>Configures non-supervisor mode write access to all RTC registers and non-supervisor mode read access to RTC tamper/monotonic registers<br>0 Non-supervisor mode write accesses are not supported and generate a bus error.<br>1 Non-supervisor mode write accesses are supported.  |

Table continues on the next page...

### RTC\_CR field descriptions (continued)

| Field    | Description   |
|----------|---|
| 1<br>WPE | <p>Wakeup Pin Enable</p> <p>The wakeup pin is optional and not available on all devices.</p> <p>0 Wakeup pin is disabled.<br/>1 Wakeup pin is enabled and wakeup pin asserts if the RTC interrupt asserts or the wakeup pin is turned on.</p> |
| 0<br>SWR | <p>Software Reset</p> <p>0 No effect.<br/>1 Resets all RTC registers except for the SWR bit and the RTC_WAR and RTC_RAR registers . The SWR bit is cleared by VBAT POR and by software explicitly clearing it.</p>                            |

### 46.2.6 RTC Status Register (RTC\_SR)

Address: 4003\_D000h base + 14h offset = 4003\_D014h

|       |          |    |    |    |    |    |    |    |          |    |    |    |          |          |          |          |

## 46.3 Functional description

### 46.3.1 Power, clocking, and reset

The RTC is an always powered block that remains active in all low power modes and is powered by the battery power supply (VBAT). The battery power supply ensures that the RTC registers retain their state during chip power-down and that the RTC time counter remains operational.

The time counter within the RTC is clocked by a 32.768 kHz clock and can supply this clock to other peripherals. The 32.768 kHz clock can only be sourced from an external crystal using the oscillator that is part of the RTC module.

The RTC includes its own analog POR block, which generates a VBAT power-on-reset signal whenever the RTC module is powered up and initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers. The RTC also monitors the chip power supply and electrically isolates itself when the rest of the chip is powered down.

#### NOTE

An attempt to access an RTC register, except the access control registers, results in a bus error when:

- VBAT is powered down,
- the RTC is electrically isolated, or
- VBAT POR is asserted.

### 46.3.1.1 Oscillator control

The 32.768 kHz crystal oscillator is disabled at VBAT POR and must be enabled by software. After enabling the crystal oscillator, wait the oscillator startup time before setting SR[TCE] or using the oscillator clock external to the RTC.

The crystal oscillator includes tunable capacitors that can be configured by software. Do not change the capacitance unless the oscillator is disabled.

### 46.3.1.2 Software reset

Writing 1 to CR[SWR] forces the equivalent of a VBAT POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software. The access control registers are not affected by either VBAT POR or the software reset; they are reset by the chip reset.

### 46.3.1.3 Supervisor access

When the supervisor access control bit is clear, only supervisor mode software can write to the RTC registers or read the RTC tamper and monotonic registers, non-supervisor mode software will generate a bus error. Both supervisor and non-supervisor mode software can always read the other RTC registers.

## 46.3.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows then the SR[TOF] will set and the time prescaler register will stop incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on VBAT POR and software reset and is cleared by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

### 46.3.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register will not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

### 46.3.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] will set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This will usually be the next alarm value, although writing a value that is less than TSR, such as 0, will prevent SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

### 46.3.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

CR[UM] also configures software write access to the Monotonic Counter Enable (MER[MCE]) bit. When CR[UM] is clear, MER[MCE] can be written only when LR[MEL] is set. When CR[UM] is set, MER[MCE] can also be written when MER[MCE] is clear or when SR[TIF] or SR[MOF] are set. This allows the monotonic counter register to be initialized whenever the monotonic counter is invalid, while preventing the monotonic counter from being changed on the fly. When LR[MEL] is set, CR[UM] has no effect on MCR[MCE].

### 46.3.6 Monotonic counter

The 64-bit Monotonic Counter is a counter that cannot be exhausted or return to any previous value, once it has been initialized. If the monotonic overflow flag is set, the monotonic counter returns zero and does not increment.

Depending on the value of the monotonic counter enable bit, writing to the monotonic counter either initializes the register with the value written, or increments the register by one (and the value written is ignored).

When the monotonic counter is enabled, the monotonic counter high increments on either a write to the monotonic counter high register or if the monotonic counter low register overflows (due to a write to the monotonic counter low register). The monotonic overflow flag sets when the monotonic counter high register overflows and is cleared by writing the monotonic counter high register when the monotonic counter is disabled.

The monotonic counter is held in reset whenever the time invalid flag is set. Always clear the time invalid flag before initializing the monotonic counter.

### 46.3.7 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next VBAT POR or software reset. Locking the Control register (CR) will disable the software reset. Locking LR will block future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

### 46.3.8 Access control

The read access and write access registers are implemented in the chip power domain and reset on the chip reset. They are not affected by the VBAT POR or the software reset. They are used to block read or write accesses to each register until the next chip system reset. When accesses are blocked, the bus access is not seen in the VBAT power supply and does not generate a bus error.

### 46.3.9 Interrupt

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on VBAT POR, and software reset, and when the VBAT power supply is powered down. The RTC interrupt is enabled at the chip level by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode. If the RTC wakeup pin is enabled and the chip is powered down, the RTC interrupt will cause the wakeup pin to assert.

#### functional description

The optional RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The RTC seconds interrupt does not cause the RTC wakeup pin to assert. This interrupt is optional and may not be implemented on all devices.

# Chapter 47

## 10/100-Mbps Ethernet MAC (ENET)

### 47.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The MAC-NET core, in conjunction with a 10/100 MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

### 47.2 Overview

The core implements a dual speed 10/100 Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100 Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable 10/100 Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

## 47.2.1 Features

The MAC-NET core includes the following features.

### 47.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100 Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism

- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors

#### 47.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking

- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

#### **47.2.1.3 IEEE 1588 features**

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

### 47.2.2 Block diagram

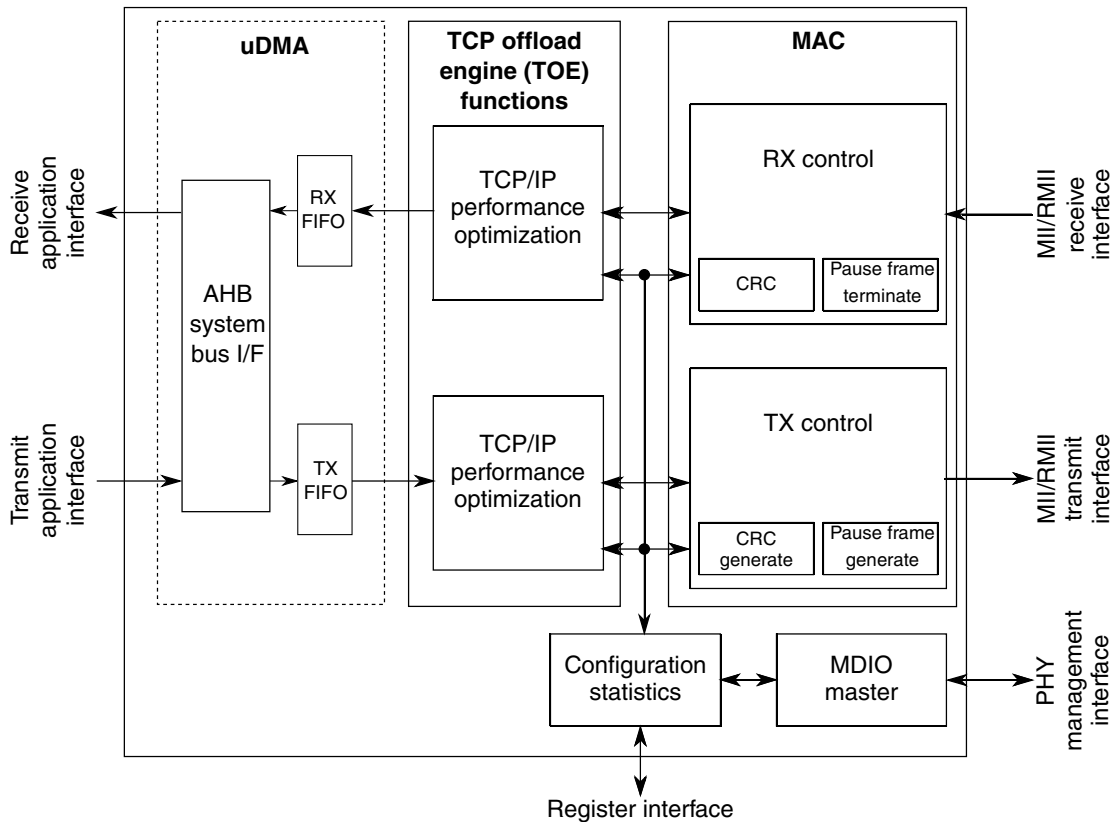

Figure 47-1. Ethernet MAC-NET core block diagram

### 47.3 External signal description

**NOTE**

The MII column pertains only to devices that support MII.

| MII     | RMII | Description   | I/O |
|---------|------|---|-----|
| MII_COL | —    | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.          | I   |
| MII_CRD | —    | Carrier sense. When asserted, indicates transmit or receive medium is not idle.<br><br>In RMII mode, this signal is present on the RMII_CRD_DV pin. | I   |

Table continues on the next page...

## external signal description

| MII          | RMII          | Description   | I/O |
|--------------|---------------|---|-----|
| MII_MDC      | RMII_MDC      | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.  | O   |
| MII_MDIO     | RMII_MDIO     | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.  | I/O |
| MII_RXCLK    | —             | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.  | I   |
| MII_RXDV     | RMII_CRSDV    | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| MII_RXD[3:0] | RMII_RXD[1:0] | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.   | I   |
| MII_RXER     | RMII_RXER     | When asserted with RXDV, indicates the PHY detects an error in the current frame.   | I   |
| MII_TXCLK    | —             | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.  | I   |
| MII_TXD[3:0] | RMII_TXD[1:0] | Serial output Ethernet data. Only valid during TXEN assertion.  | O   |
| MII_TXEN     | RMII_TXEN     | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.  | O   |
| MII_TXER     | —             | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.  | O   |

Table continues on the next page...

| MII                   | RMII                  | Description   | I/O |
|-----------------------|-----------------------|---|-----|
| —                     | RMII_REF_CLK          | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.  | I   |
| 1588_TMR <sub>n</sub> | 1588_TMR <sub>n</sub> | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<sub>n</sub> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<sub>n</sub> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<sub>n</sub>.</p> <p>An interrupt can be triggered if ENET_TCSR<sub>n</sub>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<sub>n</sub>[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN       | ENET_1588_CLKIN       | Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds   | I   |

## 47.4 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read to allow future extension. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 47-1. Register map summary**

| Offset Address  | Section               | Description  |
|-----------------|-----------------------|--|
| 0x0000 – 0x01FF | Configuration         | Core control and status registers                      |
| 0x0200 – 0x03FF | Statistics counters   | MIB and Remote Network Monitoring (RFC 2819) registers |
| 0x0400 – 0x0430 | 1588 control          | 1588 adjustable timer (TSM) and 1588 frame control     |
| 0x0600 – 0x07FC | Capture/Compare block | Registers for the Capture/Compare block                |

### ENET memory map

| Absolute address (hex) | Register name  | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|--|-----------------|--------|-------------|------------------------------|
| 400C_0004              | Interrupt Event Register (ENET_EIR)                        | 32              | w1c    | 0000_0000h  | <a href="#">47.4.1/1308</a>  |

#### 47.4.1 Interrupt Event Register (ENET\_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

#### NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

**ENET\_EIR field descriptions**

| Field          | Description   |
|----------------|---|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 30<br>BABR     | Babbling Receive Error<br>Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.  |
| 29<br>BABT     | Babbling Transmit Error<br>Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.  |
| 28<br>GRA      | Graceful Stop Complete<br>This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop.<br><b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again. |
| 27<br>TXF      | Transmit Frame Interrupt<br>Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.   |
| 26<br>TXB      | Transmit Buffer Interrupt<br>Indicates a transmit buffer descriptor has been updated.   |
| 25<br>RXF      | Receive Frame Interrupt<br>Indicates a frame has been received and the last corresponding buffer descriptor has been updated.   |

Table continues on the next page...

### ENET\_EIR field descriptions (continued)

| Field             | Description  |
|-------------------|--|
| 24<br>RXB         | Receive Buffer Interrupt<br>Indicates a receive buffer descriptor is not the last in the frame has been updated.   |
| 23<br>MII         | MII Interrupt.<br>Indicates that the MII has completed the data transfer requested.  |
| 22<br>EBERR       | Ethernet Bus Error<br>Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation. |
| 21<br>LC          | Late Collision<br>Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.  |
| 20<br>RL          | Collision Retry Limit<br>Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.   |
| 19<br>UN          | Transmit FIFO Underrun<br>Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.   |
| 18<br>PLR         | Payload Receive Error<br>Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.  |
| 17<br>WAKEUP      | Node Wakeup Request Indication<br>Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.  |
| 16<br>TS_AVAIL    | Transmit Timestamp Available<br>Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.   |
| 15<br>TS_TIMER    | Timestamp Timer<br>The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].                                  |

## 47.4.2 Interrupt Mask Register (ENET\_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

#### ENET\_RDAR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 24<br>RDAR        | Receive Descriptor Active<br><br>Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set. |
| 23–0<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 47.4.4 Transmit Descriptor Active Register (ENET\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 400C\_0000h base + 14h offset = 400C\_0014h

**ENET\_TDAR field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 24<br>TDAR        | Transmit Descriptor Active<br><br>Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set. |
| 23–0<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

**47.4.5 Ethernet Control Register (ENET\_ECR)**

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 400C\_0000h base + 24h offset = 400C\_0024h

### ENET\_ECR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–12<br>Reserved | This field is reserved.<br>This field must be set to F_0000h.   |
| 11<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 10<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 9<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 8<br>DBSWP        | Descriptor Byte Swapping Enable<br>Swaps the byte locations of the buffer descriptors.<br><b>NOTE:</b> This field must be written to 1 after reset.<br>0 The buffer descriptor bytes are not swapped to support big-endian devices.<br>1 The buffer descriptor bytes are swapped to support little-endian devices.  |
| 7<br>STOPEN       | STOPEN Signal Control<br>Controls device behavior in doze mode.<br>In doze mode, if this field is set then all the clocks of the ENET assembly are disabled, except the RMII / MII clock. Doze mode is similar to a conditional stop mode entry for the ENET assembly depending on ECR[STOPEN].<br><b>NOTE:</b> If module clocks are gated in this mode, the module can still wake the system after receiving a magic packet in stop mode. MAGICEN must be set prior to entering sleep/stop mode. |
| 6<br>DBGEN        | Debug Enable<br>Enables the MAC to enter hardware freeze mode when the device enters debug mode.<br>0 MAC continues operation in debug mode.<br>1 MAC enters hardware freeze mode when the processor is in debug mode.  |
| 5<br>Reserved     | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0.   |
| 4<br>EN1588       | EN1588 Enable<br>Enables enhanced functionality of the MAC.<br>0 Legacy FEC buffer descriptors and functions enabled.<br>1 Enhanced frame time-stamping functions enabled.  |
| 3<br>SLEEP        | Sleep Mode Enable<br>0 Normal operating mode.<br>1 Sleep mode.  |
| 2<br>MAGICEN      | Magic Packet Detection Enable<br>Enables/disables magic packet detection.<br><b>NOTE:</b> MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection.<br>0 Magic detection logic disabled.<br>1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.  |

**47.4.6 MII Management Frame Register (ENET\_MMFR)**

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 400C\_0000h base + 40h offset = 400C\_0040h

#### 47.4.7 MII Speed Control Register (ENET\_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

If the internal module clock is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of internal module clock frequency.

**Table 47-10. Programming Examples for MSCR**

| Internal MAC clock frequency | MSCR [MII_SPEED] | MDC frequency |
|------------------------------|------------------|---------------|
| 25 MHz                       | 0x4              | 2.50 MHz      |
| 33 MHz                       | 0x6              | 2.36 MHz      |
| 40 MHz                       | 0x7              | 2.50 MHz      |
| 50 MHz                       | 0x9              | 2.50 MHz      |

*Table continues on the next page...*

| 1<br>DRT       | <p>Disable Receive On Transmit</p> <p>0 Receive path operates independently of transmit. Used for full-duplex or to monitor transmit activity in half-duplex mode.<br/>1 Disable reception of frames while transmitting. Normally used for half-duplex mode.</p>   |
| 0<br>LOOP      | <p>Internal Loopback</p> <p>This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</p> <p>0 Loopback disabled.<br/>1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</p> |

### 47.4.10 Transmit Control Register (ENET\_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 400C\_0000h base + C4h offset = 400C\_00C4h

**ENET\_TCR field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10<br>Reserved    | This field is reserved.<br>This field is read/write and must be set to 0.               |
| 9<br>CRCFWD       | Forward Frame From Application With CRC   |

*Table continues on the next page...*

**ENET\_TCR field descriptions (continued)**

| Field          | Description  |
|----------------|--|
|                | 0 TxBD[TC] controls whether the frame has a CRC from the application.<br>1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.  |
| 8<br>ADDINS    | Set MAC Address On Transmit<br><br>0 The source MAC address is not modified by the MAC.<br>1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.  |
| 7–5<br>ADDSEL  | Source MAC Address Select On Transmit<br><br>If ADDINS is set, indicates the MAC address that overwrites the source MAC address.<br><br>000 Node MAC address programmed on PADDR1/2 registers.<br>100 Reserved.<br>101 Reserved.<br>110 Reserved.  |
| 4<br>RFC_PAUSE | Receive Frame Control Pause<br><br>This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.  |
| 3<br>TFC_PAUSE | Transmit Frame Control Pause<br><br>Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.<br><br>0 No PAUSE frame transmitted.<br>1 The MAC stops transmission of data frames after the current transmission is complete.   |
| 2<br>FDEN      | Full-Duplex Enable<br><br>If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.  |
| 1<br>Reserved  | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0.  |
| 0<br>GTS       | Graceful Transmit Stop<br><br>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt. |

### 47.4.11 Physical Address Lower Register (ENET\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 400C\_0000h base + E4h offset = 400C\_00E4h

#### ENET\_PALR field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>PADDR1 | Pause Address<br><br>Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames. |

### 47.4.12 Physical Address Upper Register (ENET\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 400C\_0000h base + E8h offset = 400C\_00E8h

#### ENET\_PAUR field descriptions

| Field           | Description  |
|-----------------|--|
| 31–16<br>PADDR2 | Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames. |
| 15–0<br>TYPE    | Type Field In PAUSE Frames<br><br>These fields have a constant value of 0x8808.  |

### 47.4.13 Opcode/Pause Duration Register (ENET\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 400C\_0000h base + ECh offset = 400C\_00ECh

#### ENET\_OPD field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>OPCODE   | Opcode Field In PAUSE Frames<br>These fields have a constant value of 0x0001. |
| 15–0<br>PAUSE_DUR | Pause Duration<br>Pause duration field used in PAUSE frames.                  |

### 47.4.14 Descriptor Individual Upper Address Register (ENET\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 400C\_0000h base + 118h offset = 400C\_0118h

#### ENET\_IAUR field descriptions

| Field          | Description   |
|----------------|---|
| 31–0<br>IADDR1 | Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32. |

### 47.4.15 Descriptor Individual Lower Address Register (ENET\_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 400C\_0000h base + 11Ch offset = 400C\_011Ch

#### ENET\_IALR field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>IADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0. |

### 47.4.16 Descriptor Group Upper Address Register (ENET\_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 400C\_0000h base + 120h offset = 400C\_0120h

#### ENET\_GAUR field descriptions

| Field          | Description   |
|----------------|---|
| 31–0<br>GADDR1 | Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32. |

### 47.4.17 Descriptor Group Lower Address Register (ENET\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 400C\_0000h base + 124h offset = 400C\_0124h

#### ENET\_GALR field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>GADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0. |

### 47.4.18 Transmit FIFO Watermark Register (ENET\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

**memory map/register definition**

Address: 400C\_0000h base + 144h offset = 400C\_0144h

**ENET\_TFWR field descriptions**

| Field            | Description  |

**ENET\_TDSR field descriptions**

| Field               | Description   |
|---------------------|---|
| 31–3<br>X_DES_START | Pointer to the beginning of the transmit buffer descriptor queue. |

*Table continues on the next page...*

### ENET\_TDSR field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 2<br>Reserved   | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0. |
| 1-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                   |

### 47.4.21 Maximum Receive Buffer Size Register (ENET\_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

#### NOTE

This register must be initialized before operation.

Address: 400C\_0000h base + 188h offset = 400C\_0188h

### ENET\_MRBR field descriptions

| Field              | Description   |
|--------------------|---|
| 31-11<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 10-4<br>R_BUF_SIZE | Receive buffer size in bytes.   |
| 3-0<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 47.4.22 Receive FIFO Section Full Threshold (ENET\_RSFL)

Address: 400C\_0000h base + 190h offset = 400C\_0190h

#### ENET\_RSFL field descriptions

| Field                  | Description   |
|------------------------|---|
| 31–8<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>RX_SECTION_FULL | Value Of Receive FIFO Section Full Threshold<br>Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY].<br>When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation). |

### 47.4.23 Receive FIFO Section Empty Threshold (ENET\_RSEM)

Address: 400C\_0000h base + 194h offset = 400C\_0194h

#### ENET\_RSEM field descriptions

| Field                   | Description   |
|-------------------------|---|
| 31–21<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 20–16<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 15–8<br>Reserved        | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>RX_SECTION_EMPTY | Value Of The Receive FIFO Section Empty Threshold<br>Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued.<br>A value of 0 disables automatic pause frame generation.<br>When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. |

Table continues on the next page...

### ENET\_RSEM field descriptions (continued)

| Field | Description  |
|-------|--|
|       | <b>NOTE:</b> The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation. |

### 47.4.24 Receive FIFO Almost Empty Threshold (ENET\_RAEM)

Address: 400C\_0000h base + 198h offset = 400C\_0198h

#### ENET\_RAEM field descriptions

| Field                  | Description   |
|------------------------|---|
| 31–8<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>RX_ALMOST_EMPTY | Value Of The Receive FIFO Almost Empty Threshold<br><br>Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set. |

### 47.4.25 Receive FIFO Almost Full Threshold (ENET\_RAFL)

Address: 400C\_0000h base + 19Ch offset = 400C\_019Ch

#### ENET\_RAFL field descriptions

| Field                 | Description  |
|-----------------------|--|
| 31–8<br>Reserved      | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7–0<br>RX_ALMOST_FULL | Value Of The Receive FIFO Almost Full Threshold<br><br>Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set. |

### 47.4.26 Transmit FIFO Section Empty Threshold (ENET\_TSEM)

Address: 400C\_0000h base + 1A0h offset = 400C\_01A0h

#### ENET\_TSEM field descriptions

| Field                   | Description   |
|-------------------------|---|
| 31–8<br>Reserved        | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>TX_SECTION_EMPTY | Value Of The Transmit FIFO Section Empty Threshold<br>Value, in 64-bit words, of the transmit FIFO section empty threshold. See <a href="#">Transmit FIFO</a> for more information. |

### 47.4.27 Transmit FIFO Almost Empty Threshold (ENET\_TAEM)

Address: 400C\_0000h base + 1A4h offset = 400C\_01A4h

#### ENET\_TAEM field descriptions

| Field                  | Description   |
|------------------------|---|
| 31–8<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 7–0<br>TX_ALMOST_EMPTY | Value of Transmit FIFO Almost Empty Threshold<br>Value, in 64-bit words, of the transmit FIFO almost empty threshold.<br>When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See <a href="#">Transmit FIFO</a> for more information.<br>A minimum value of 4 should be set. |

## 47.4.28 Transmit FIFO Almost Full Threshold (ENET\_TAFL)

Address: 400C\_0000h base + 1A8h offset = 400C\_01A8h

### ENET\_TAFL field descriptions

| Field                 | Description  |
|-----------------------|--|
| 31–8<br>Reserved      | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 7–0<br>TX_ALMOST_FULL | Value Of The Transmit FIFO Almost Full Threshold<br><br>Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).<br><br>When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.<br><br><b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN. |

## 47.4.29 Transmit Inter-Packet Gap (ENET\_TIPG)

Address: 400C\_0000h base + 1ACh offset = 400C\_01ACh

### ENET\_TIPG field descriptions

| Field            | Description   |
|------------------|---|
| 31–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 4–0<br>IPG       | Transmit Inter-Packet Gap<br><br>Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12.<br><br><b>NOTE:</b> The IPG value read will be the value that was written, even if it is out of range. |

### 47.4.30 Frame Truncation Length (ENET\_FTRL)

Address: 400C\_0000h base + 1B0h offset = 400C\_01B0h

#### ENET\_FTRL field descriptions

| Field             | Description  |
|-------------------|--|
| 31–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 13–0<br>TRUNC_FL  | Frame Truncation Length<br>Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].<br><b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit. |

### 47.4.31 Transmit Accelerator Function Configuration (ENET\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 400C\_0000h base + 1C0h offset = 400C\_01C0h

### ENET\_TACC field descriptions

| Field            | Description  |
|------------------|--|
| 31–5<br>Reserved | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0.  |
| 4<br>PROCHK      | Enables insertion of protocol checksum.<br>0 Checksum not inserted.<br>1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.  |
| 3<br>IPCHK       | Enables insertion of IP header checksum.<br>0 Checksum is not inserted.<br>1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.  |
| 2–1<br>Reserved  | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0.  |
| 0<br>SHIFT16     | TX FIFO Shift-16<br>0 Disabled.<br>1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header. |

### 47.4.32 Receive Accelerator Function Configuration (ENET\_RACC)

Address: 400C\_0000h base + 1C4h offset = 400C\_01C4h

|       |            |    |    |    |    |    |    |    |         |         |            |    |    |        |       |        |
|-------|------------|----|----|----|----|----|----|----|---------|---------|------------|----|----|--------|-------|--------|
| Bit   | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23      | 22      | 21         | 20 | 19 | 18     | 17    | 16     |
| R     | [Reserved] |    |    |    |    |    |    |    |         |         |            |    |    |        |       |        |
| W     | 0          |    |    |    |    |    |    |    |         |         |            |    |    |        |       |        |
| Reset | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0       | 0       | 0          | 0  | 0  | 0      | 0     | 0      |
| Bit   | 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7       | 6       | 5          | 4  | 3  | 2      | 1     | 0      |
| R     | [Reserved] |    |    |    |    |    |    |    | SHIFT16 | LINEDIS | [Reserved] |    |    | PRODIS | IPDIS | PADREM |
| W     | 0          |    |    |    |    |    |    |    | SHIFT16 | LINEDIS | 0          |    |    | PRODIS | IPDIS | PADREM |
| Reset | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0       | 0       | 0          | 0  | 0  | 0      | 0     | 0      |

### ENET\_RACC field descriptions

| Field            | Description   |
|------------------|---|
| 31–8<br>Reserved | This field is reserved.<br>This write-only field is reserved. It must always be written with the value 0. |

Table continues on the next page...

### ENET\_RACC field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 7<br>SHIFT16    | <p>RX FIFO Shift-16</p> <p>When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary.</p> <p><b>NOTE:</b> This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received.</p> <p>0 Disabled.<br/>1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.</p> |
| 6<br>LINEDIS    | <p>Enable Discard Of Frames With MAC Layer Errors</p> <p>0 Frames with errors are not discarded.<br/>1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.</p>  |
| 5–3<br>Reserved | <p>This field is reserved.<br/>This write-only field is reserved. It must always be written with the value 0.</p>   |
| 2<br>PRODIS     | <p>Enable Discard Of Frames With Wrong Protocol Checksum</p> <p>0 Frames with wrong checksum are not discarded.<br/>1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>   |
| 1<br>IPDIS      | <p>Enable Discard Of Frames With Wrong IPv4 Header Checksum</p> <p>0 Frames with wrong IPv4 header checksum are not discarded.<br/>1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>   |
| 0<br>PADREM     | <p>Enable Padding Removal For Short IP Frames</p> <p>0 Padding not removed.<br/>1 Any bytes following the IP payload section of the frame are removed from the frame.</p>   |

### 47.4.33 Reserved Statistic Register (ENET\_RMON\_T\_DROP)

Address: 400C\_0000h base + 200h offset = 400C\_0200h

### ENET\_RMON\_T\_DROP field descriptions

| Field            | Description   |

| 31–0<br>Reserved | <p>This read-only field always has the value 0.<br/>This field is reserved.</p> |

### 47.4.34 Tx Packet Count Statistic Register (ENET\_RMON\_T\_PACKETS)

Address: 400C\_0000h base + 204h offset = 400C\_0204h

#### ENET\_RMON\_T\_PACKETS field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Packet count<br>Transmit packet count   |

### 47.4.35 Tx Broadcast Packets Statistic Register (ENET\_RMON\_T\_BC\_PKT)

RMON Tx Broadcast Packets

Address: 400C\_0000h base + 208h offset = 400C\_0208h

#### ENET\_RMON\_T\_BC\_PKT field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Broadcast packets   |

### 47.4.36 Tx Multicast Packets Statistic Register (ENET\_RMON\_T\_MC\_PKT)

Address: 400C\_0000h base + 20Ch offset = 400C\_020Ch

#### ENET\_RMON\_T\_MC\_PKT field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Multicast packets   |

### 47.4.37 Tx Packets with CRC/Align Error Statistic Register (ENET\_RMON\_T\_CRC\_ALIGN)

Address: 400C\_0000h base + 210h offset = 400C\_0210h

#### ENET\_RMON\_T\_CRC\_ALIGN field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Packets with CRC/align error  |

### 47.4.38 Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET\_RMON\_T\_UNDERSIZE)

Address: 400C\_0000h base + 214h offset = 400C\_0214h

#### ENET\_RMON\_T\_UNDERSIZE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of transmit packets less than 64 bytes with good CRC                             |

### 47.4.39 Tx Packets GT MAX\_FL bytes and Good CRC Statistic Register (ENET\_RMON\_T\_OVERSIZE)

Address: 400C\_0000h base + 218h offset = 400C\_0218h

#### ENET\_RMON\_T\_OVERSIZE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of transmit packets greater than MAX_FL bytes with good CRC                      |

### 47.4.40 Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET\_RMON\_T\_FRAG)

Address: 400C\_0000h base + 21Ch offset = 400C\_021Ch

#### ENET\_RMON\_T\_FRAG field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of packets less than 64 bytes with bad CRC                                       |

### 47.4.41 Tx Packets Greater Than MAX\_FL bytes and Bad CRC Statistic Register (ENET\_RMON\_T\_JAB)

Address: 400C\_0000h base + 220h offset = 400C\_0220h

#### ENET\_RMON\_T\_JAB field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of transmit packets greater than MAX_FL bytes and bad CRC                        |

### 47.4.42 Tx Collision Count Statistic Register (ENET\_RMON\_T\_COL)

Address: 400C\_0000h base + 224h offset = 400C\_0224h

#### ENET\_RMON\_T\_COL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of transmit collisions   |

### 47.4.43 Tx 64-Byte Packets Statistic Register (ENET\_RMON\_T\_P64)

Address: 400C\_0000h base + 228h offset = 400C\_0228h

#### ENET\_RMON\_T\_P64 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 64-byte transmit packets  |

### 47.4.44 Tx 65- to 127-byte Packets Statistic Register (ENET\_RMON\_T\_P65TO127)

Address: 400C\_0000h base + 22Ch offset = 400C\_022Ch

#### ENET\_RMON\_T\_P65TO127 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 65- to 127-byte transmit packets  |

### 47.4.45 Tx 128- to 255-byte Packets Statistic Register (ENET\_RMON\_T\_P128TO255)

Address: 400C\_0000h base + 230h offset = 400C\_0230h

#### ENET\_RMON\_T\_P128TO255 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 128- to 255-byte transmit packets   |

### 47.4.46 Tx 256- to 511-byte Packets Statistic Register (ENET\_RMON\_T\_P256TO511)

Address: 400C\_0000h base + 234h offset = 400C\_0234h

#### ENET\_RMON\_T\_P256TO511 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 256- to 511-byte transmit packets   |

### 47.4.47 Tx 512- to 1023-byte Packets Statistic Register (ENET\_RMON\_T\_P512TO1023)

Address: 400C\_0000h base + 238h offset = 400C\_0238h

#### ENET\_RMON\_T\_P512TO1023 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 512- to 1023-byte transmit packets  |

### 47.4.48 Tx 1024- to 2047-byte Packets Statistic Register (ENET\_RMON\_T\_P1024TO2047)

Address: 400C\_0000h base + 23Ch offset = 400C\_023Ch

#### ENET\_RMON\_T\_P1024TO2047 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of 1024- to 2047-byte transmit packets   |

### 47.4.49 Tx Packets Greater Than 2048 Bytes Statistic Register (ENET\_RMON\_T\_P\_GTE2048)

Address: 400C\_0000h base + 240h offset = 400C\_0240h

#### ENET\_RMON\_T\_P\_GTE2048 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>TXPKTS    | Number of transmit packets greater than 2048 bytes                                      |

### 47.4.50 Tx Octets Statistic Register (ENET\_RMON\_T\_OCTETS)

Address: 400C\_0000h base + 244h offset = 400C\_0244h

#### ENET\_RMON\_T\_OCTETS field descriptions

| Field          | Description               |
|----------------|---------------------------|
| 31–0<br>TXOCTS | Number of transmit octets |

### 47.4.51 IEEE\_T\_DROP Reserved Statistic Register (ENET\_IEEE\_T\_DROP)

Address: 400C\_0000h base + 248h offset = 400C\_0248h

#### ENET\_IEEE\_T\_DROP field descriptions

| Field            | Description   |
|------------------|---|
| 31–0<br>Reserved | This read-only field always has the value 0.<br><br>This field is reserved. |

### 47.4.52 Frames Transmitted OK Statistic Register (ENET\_IEEE\_T\_FRAME\_OK)

Address: 400C\_0000h base + 24Ch offset = 400C\_024Ch

### ENET\_IEEE\_T\_FRAME\_OK field descriptions

| Field             | Description  |
|-------------------|--|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 15–0<br>COUNT     | Number of frames transmitted OK<br><br><b>NOTE:</b> Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR). |

### 47.4.53 Frames Transmitted with Single Collision Statistic Register (ENET\_IEEE\_T\_1COL)

Address: 400C\_0000h base + 250h offset = 400C\_0250h

### ENET\_IEEE\_T\_1COL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with one collision   |

### 47.4.54 Frames Transmitted with Multiple Collisions Statistic Register (ENET\_IEEE\_T\_MCOL)

Address: 400C\_0000h base + 254h offset = 400C\_0254h

### ENET\_IEEE\_T\_MCOL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with multiple collisions                                   |

### 47.4.55 Frames Transmitted after Deferral Delay Statistic Register (ENET\_IEEE\_T\_DEF)

Address: 400C\_0000h base + 258h offset = 400C\_0258h

#### ENET\_IEEE\_T\_DEF field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with deferral delay  |

### 47.4.56 Frames Transmitted with Late Collision Statistic Register (ENET\_IEEE\_T\_LCOL)

Address: 400C\_0000h base + 25Ch offset = 400C\_025Ch

#### ENET\_IEEE\_T\_LCOL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with late collision  |

### 47.4.57 Frames Transmitted with Excessive Collisions Statistic Register (ENET\_IEEE\_T\_EXCOL)

Address: 400C\_0000h base + 260h offset = 400C\_0260h

#### ENET\_IEEE\_T\_EXCOL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with excessive collisions                                  |

### 47.4.58 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET\_IEEE\_T\_MACERR)

Address: 400C\_0000h base + 264h offset = 400C\_0264h

#### ENET\_IEEE\_T\_MACERR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with transmit FIFO underrun                                |

### 47.4.59 Frames Transmitted with Carrier Sense Error Statistic Register (ENET\_IEEE\_T\_CSERR)

Address: 400C\_0000h base + 268h offset = 400C\_0268h

#### ENET\_IEEE\_T\_CSERR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames transmitted with carrier sense error                                   |

### 47.4.60 ENET\_IEEE\_T\_SQE

Address: 400C\_0000h base + 26Ch offset = 400C\_026Ch

#### ENET\_IEEE\_T\_SQE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 15–0<br>COUNT     | Number of frames transmitted with SQE error<br><br><b>NOTE:</b> Counter not implemented (always reads zero) as no SQE information is available. |

### 47.4.61 Flow Control Pause Frames Transmitted Statistic Register (ENET\_IEEE\_T\_FDXFC)

Address: 400C\_0000h base + 270h offset = 400C\_0270h

#### ENET\_IEEE\_T\_FDXFC field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of flow-control pause frames transmitted   |

### 47.4.62 Octet Count for Frames Transmitted w/o Error Statistic Register (ENET\_IEEE\_T\_OCTETS\_OK)

Address: 400C\_0000h base + 274h offset = 400C\_0274h

#### ENET\_IEEE\_T\_OCTETS\_OK field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>COUNT | Octet count for frames transmitted without error<br><br><b>NOTE</b><br>Counts total octets (includes header and FCS fields). |

### 47.4.63 Rx Packet Count Statistic Register (ENET\_RMON\_R\_PACKETS)

Address: 400C\_0000h base + 284h offset = 400C\_0284h

#### ENET\_RMON\_R\_PACKETS field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of packets received  |

### 47.4.64 Rx Broadcast Packets Statistic Register (ENET\_RMON\_R\_BC\_PKT)

Address: 400C\_0000h base + 288h offset = 400C\_0288h

#### ENET\_RMON\_R\_BC\_PKT field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive broadcast packets   |

### 47.4.65 Rx Multicast Packets Statistic Register (ENET\_RMON\_R\_MC\_PKT)

Address: 400C\_0000h base + 28Ch offset = 400C\_028Ch

#### ENET\_RMON\_R\_MC\_PKT field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive multicast packets   |

### 47.4.66 Rx Packets with CRC/Align Error Statistic Register (ENET\_RMON\_R\_CRC\_ALIGN)

Address: 400C\_0000h base + 290h offset = 400C\_0290h

#### ENET\_RMON\_R\_CRC\_ALIGN field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive packets with CRC or align error                                       |

### 47.4.67 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENET\_RMON\_R\_UNDERSIZE)

Address: 400C\_0000h base + 294h offset = 400C\_0294h

#### ENET\_RMON\_R\_UNDERSIZE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive packets with less than 64 bytes and good CRC                          |

### 47.4.68 Rx Packets Greater Than MAX\_FL and Good CRC Statistic Register (ENET\_RMON\_R\_OVERSIZE)

Address: 400C\_0000h base + 298h offset = 400C\_0298h

#### ENET\_RMON\_R\_OVERSIZE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive packets greater than MAX_FL and good CRC                              |

### 47.4.69 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET\_RMON\_R\_FRAG)

Address: 400C\_0000h base + 29Ch offset = 400C\_029Ch

**ENET\_RMON\_R\_FRAG field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive packets with less than 64 bytes and bad CRC                           |

### 47.4.70 Rx Packets Greater Than MAX\_FL Bytes and Bad CRC Statistic Register (ENET\_RMON\_R\_JAB)

Address: 400C\_0000h base + 2A0h offset = 400C\_02A0h

**ENET\_RMON\_R\_JAB field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of receive packets greater than MAX_FL and bad CRC                               |

### 47.4.71 Reserved Statistic Register (ENET\_RMON\_R\_RESVD\_0)

Address: 400C\_0000h base + 2A4h offset = 400C\_02A4h

### ENET\_RMON\_R\_RESVD\_0 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 47.4.72 Rx 64-Byte Packets Statistic Register (ENET\_RMON\_R\_P64)

Address: 400C\_0000h base + 2A8h offset = 400C\_02A8h

|       |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### ENET\_RMON\_R\_P65TO127 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of 65- to 127-byte receive packets   |

### 47.4.74 Rx 128- to 255-Byte Packets Statistic Register (ENET\_RMON\_R\_P128TO255)

Address: 400C\_0000h base + 2B0h offset = 400C\_02B0h

#### ENET\_RMON\_R\_P128TO255 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of 128- to 255-byte receive packets  |

### 47.4.75 Rx 256- to 511-Byte Packets Statistic Register (ENET\_RMON\_R\_P256TO511)

Address: 400C\_0000h base + 2B4h offset = 400C\_02B4h

#### ENET\_RMON\_R\_P256TO511 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of 256- to 511-byte receive packets  |

### 47.4.76 Rx 512- to 1023-Byte Packets Statistic Register (ENET\_RMON\_R\_P512TO1023)

Address: 400C\_0000h base + 2B8h offset = 400C\_02B8h

#### ENET\_RMON\_R\_P512TO1023 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of 512- to 1023-byte receive packets   |

### 47.4.77 Rx 1024- to 2047-Byte Packets Statistic Register (ENET\_RMON\_R\_P1024TO2047)

Address: 400C\_0000h base + 2BCh offset = 400C\_02BCh

#### ENET\_RMON\_R\_P1024TO2047 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of 1024- to 2047-byte receive packets  |

### 47.4.78 Rx Packets Greater than 2048 Bytes Statistic Register (ENET\_RMON\_R\_P\_GTE2048)

Address: 400C\_0000h base + 2C0h offset = 400C\_02C0h

**ENET\_RMON\_R\_P\_GTE2048 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of greater-than-2048-byte receive packets  |

### 47.4.79 Rx Octets Statistic Register (ENET\_RMON\_R\_OCTETS)

Address: 400C\_0000h base + 2C4h offset = 400C\_02C4h

**ENET\_RMON\_R\_OCTETS field descriptions**

| Field         | Description              |
|---------------|--------------------------|
| 31–0<br>COUNT | Number of receive octets |

### 47.4.80 Frames not Counted Correctly Statistic Register (ENET\_IEEE\_R\_DROP)

Counter increments if a frame with invalid or missing SFD character is detected and has been dropped. None of the other counters increments if this counter increments.

Address: 400C\_0000h base + 2C8h offset = 400C\_02C8h

**ENET\_IEEE\_R\_DROP field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Frame count   |

### 47.4.81 Frames Received OK Statistic Register (ENET\_IEEE\_R\_FRAME\_OK)

Address: 400C\_0000h base + 2CCh offset = 400C\_02CCh

**ENET\_IEEE\_R\_FRAME\_OK field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames received OK  |

### 47.4.82 Frames Received with CRC Error Statistic Register (ENET\_IEEE\_R\_CRC)

Address: 400C\_0000h base + 2D0h offset = 400C\_02D0h

#### ENET\_IEEE\_R\_CRC field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames received with CRC error  |

### 47.4.83 Frames Received with Alignment Error Statistic Register (ENET\_IEEE\_R\_ALIGN)

Address: 400C\_0000h base + 2D4h offset = 400C\_02D4h

#### ENET\_IEEE\_R\_ALIGN field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of frames received with alignment error  |

### 47.4.84 Receive FIFO Overflow Count Statistic Register (ENET\_IEEE\_R\_MACERR)

Address: 400C\_0000h base + 2D8h offset = 400C\_02D8h

#### ENET\_IEEE\_R\_MACERR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Receive FIFO overflow count   |

### 47.4.85 Flow Control Pause Frames Received Statistic Register (ENET\_IEEE\_R\_FDXFC)

Address: 400C\_0000h base + 2DCh offset = 400C\_02DCh

#### ENET\_IEEE\_R\_FDXFC field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 15–0<br>COUNT     | Number of flow-control pause frames received  |

### 47.4.86 Octet Count for Frames Received without Error Statistic Register (ENET\_IEEE\_R\_OCTETS\_OK)

Address: 400C\_0000h base + 2E0h offset = 400C\_02E0h

#### ENET\_IEEE\_R\_OCTETS\_OK field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>COUNT | <p>Number of octets for frames received without error</p> <p><b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).</p> |

### 47.4.87 Adjustable Timer Control Register (ENET\_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

Address: 400C\_0000h base + 400h offset = 400C\_0400h

### ENET\_ATCR field descriptions

| Field             | Description  |
|-------------------|--|
| 31–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 13<br>SLAVE       | Enable Timer Slave Mode<br><br>0 The timer is active and all configuration fields in this register are relevant.<br>1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.   |
| 12<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 11<br>CAPTURE     | Capture Timer Value<br><br>This field automatically clears to 0 after the command completes.<br><br><b>NOTE:</b> To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles.<br><br>0 No effect.<br>1 The current time is captured and can be read from the ATVR register.  |
| 10<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 9<br>RESTART      | Reset Timer<br><br>Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.<br><br><b>NOTE:</b> The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete. |
| 8<br>Reserved     | This field is reserved.  |
| 7<br>PINPER       | Enables event signal output assertion on period event.<br><br><b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.<br><br>0 Disable.<br>1 Enable.   |
| 6<br>Reserved     | This field is reserved.  |
| 5<br>Reserved     | This field is reserved.<br><br><b>NOTE:</b> This field must be written always with one.  |
| 4<br>PEREN        | Enable Periodical Event<br><br>0 Disable.<br>1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit.<br><br><b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.   |

Table continues on the next page...

### ENET\_ATCR field descriptions (continued)

| Field         | Description  |
|---------------|--|
| 3<br>OFFRST   | Reset Timer On Offset Event<br>0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached.<br>1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.   |
| 2<br>OFFEN    | Enable One-Shot Offset Event<br>0 Disable.<br>1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field. |
| 1<br>Reserved | This field is reserved.  |
| 0<br>EN       | Enable Timer<br>0 The timer stops at the current value.<br>1 The timer starts incrementing.  |

### 47.4.88 Timer Value Register (ENET\_ATVR)

Address: 400C\_0000h base + 404h offset = 400C\_0404h

#### ENET\_ATVR field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>ATIME | A write sets the timer. A read returns the last captured value. To read the current value, issue a capture command (i.e., set ATCR[CAPTURE]) prior to reading this register. |

### 47.4.89 Timer Offset Register (ENET\_ATOFF)

Address: 400C\_0000h base + 408h offset = 400C\_0408h

### ENET\_ATOFF field descriptions

| Field          | Description   |
|----------------|---|
| 31–0<br>OFFSET | Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. |

### 47.4.90 Timer Period Register (ENET\_ATPER)

Address: 400C\_0000h base + 40Ch offset = 400C\_040Ch

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 1  | 1  | 1  | 0  | 1  | 1  | 1  | 0  | 0  | 1  | 1  | 0  | 1  | 0  | 1  | 1  | 0  | 0  | 1  | 0  | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### ENET\_ATPER field descriptions

| Field          | Description   |
|----------------|---|
| 31–0<br>PERIOD | Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10 <sup>9</sup> ) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. |

### 47.4.91 Timer Correction Register (ENET\_ATCOR)

Address: 400C\_0000h base + 410h offset = 400C\_0410h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

|       |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### ENET\_ATCOR field descriptions

| Field          | Description  |
|----------------|--|
| 31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 30–0<br>COR    | Correction Counter Wrap-Around Value<br><br>Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur.<br><br><b>NOTE:</b> This value is given in clock cycles, not in nanoseconds as all other values. |

### 47.4.92 Time-Stamping Clock Period Register (ENET\_ATINC)

Address: 400C\_0000h base + 414h offset = 400C\_0414h

#### ENET\_ATINC field descriptions

| Field             | Description  |
|-------------------|--|
| 31–15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 14–8<br>INC_CORR  | Correction Increment Value<br><br>This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.  |
| 7<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 6–0<br>INC        | Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds<br><br>The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz.<br><br><b>NOTE:</b> For highest precision, use a value that is an integer fraction of the period set in ATPER. |

### 47.4.93 Timestamp of Last Transmitted Frame (ENET\_ATSTMP)

Address: 400C\_0000h base + 418h offset = 400C\_0418h

#### ENET\_ATSTMP field descriptions

| Field             | Description  |
|-------------------|--|
| 31–0<br>TIMESTAMP | Timestamp of the last frame transmitted by the core that had TxBD[TS] set . This register is only valid when EIR[TS_AVAIL] is set. |

### 47.4.94 Timer Global Status Register (ENET\_TGSR)

Address: 400C\_0000h base + 604h offset = 400C\_0604h

|       |    |    |    |    |    |    |    |    |  |    |    |    |     |     |     |     |    |
|-------|----|----|----|----|----|----|----|----|--|----|----|----|-----|-----|-----|-----|----|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |  | 23 | 22 | 21 | 20  | 19  | 18  | 17  | 16 |
| R     | 0  |    |    |    |    |    |    |    |  |    |    |    |     |     |     |     |    |
| W     |    |    |    |    |    |    |    |    |  |    |    |    |     |     |     |     |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |  | 0  | 0  | 0  | 0   | 0   | 0   | 0   | 0  |
| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  |  | 7  | 6  | 5  | 4   | 3   | 2   | 1   | 0  |
| R     | 0  |    |    |    |    |    |    |    |  |    |    |    | TF3 | TF2 | TF1 | TF0 |    |
| W     |    |    |    |    |    |    |    |    |  |    |    |    | w1c | w1c | w1c | w1c |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |  | 0  | 0  | 0  | 0   | 0   | 0   | 0   | 0  |

#### ENET\_TGSR field descriptions

| Field            | Description  |
|------------------|--|
| 31–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                      |
| 3<br>TF3         | Copy Of Timer Flag For Channel 3<br>0 Timer Flag for Channel 3 is clear<br>1 Timer Flag for Channel 3 is set |
| 2<br>TF2         | Copy Of Timer Flag For Channel 2<br>0 Timer Flag for Channel 2 is clear<br>1 Timer Flag for Channel 2 is set |
| 1<br>TF1         | Copy Of Timer Flag For Channel 1<br>0 Timer Flag for Channel 1 is clear<br>1 Timer Flag for Channel 1 is set |
| 0<br>TF0         | Copy Of Timer Flag For Channel 0<br>0 Timer Flag for Channel 0 is clear<br>1 Timer Flag for Channel 0 is set |

### 47.4.95 Timer Control Status Register (ENET\_TCSRn)

Address: 400C\_0000h base + 608h offset + (8d × i), where i=0d to 3d

|       |    |    |    |    |    |    |    |    |     |     |       |    |    |    |    |      |

### 47.4.96 Timer Compare Capture Register (ENET\_TCCR<sub>n</sub>)

Address: 400C\_0000h base + 60Ch offset + (8d × i), where i=0d to 3d

### ENET\_TCCR<sub>n</sub> field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>TCC | <p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p> |

## 47.5 Functional description

This section provides a complete functional description of the MAC-NET core.

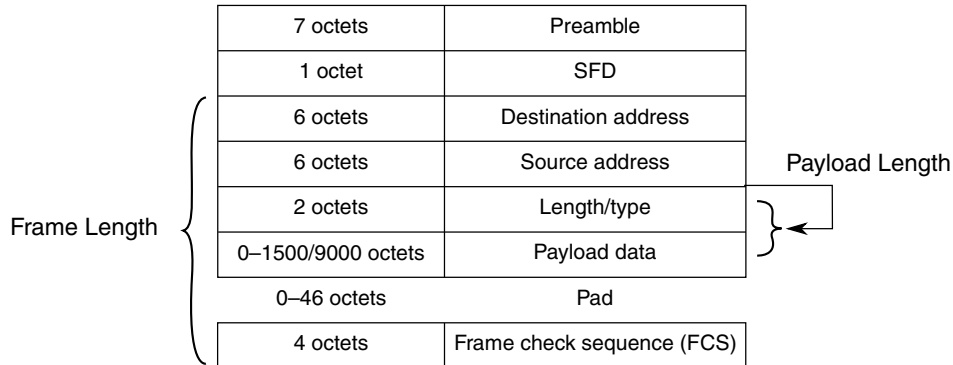

## 47.5.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

**Figure 47-106. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

**Figure 47-107. VLAN-tagged MAC frame format overview**

**Table 47-108. MAC frame definition**

| Term                           | Description   |
|--------------------------------|---|
| Frame length                   | Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.  |
| Payload length                 | The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"> <li>If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li> <li>If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li> </ul> |
| Destination and source address | 48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .  |

**Note**

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

**47.5.1.1 Pause Frames**

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 47-109. Pause Frame Format (Values in Hex)**

|                |    |    |    |    |    |      |     |                               |    |    |    |          |    |
|----------------|----|----|----|----|----|------|-----|-------------------------------|----|----|----|----------|----|
| 1              | 2  | 3  | 4  | 5  | 6  | 7    | 8   | 9                             | 10 | 11 | 12 | 13       | 14 |
| 55             | 55 | 55 | 55 | 55 | 55 | 55   | D5  | 01                            | 80 | C2 | 00 | 00       | 01 |
| Preamble       |    |    |    |    |    |      | SFD | Multicast Destination Address |    |    |    |          |    |
| 15             | 16 | 17 | 18 | 19 | 20 | 21   | 22  | 23                            | 24 | 25 | 26 | 27–68    |    |
| 00             | 00 | 00 | 00 | 00 | 00 | 88   | 08  | 00                            | 01 | hi | lo | 00       |    |
| Source Address |    |    |    |    |    | Type |     | Opcode                        |    | P1 | P2 | pad (42) |    |
| 69             | 70 | 71 | 72 |    |    |      |     |                               |    |    |    |          |    |
| 26             | 6B | AE | 0A |    |    |      |     |                               |    |    |    |          |    |
| CRC-32         |    |    |    |    |    |      |     |                               |    |    |    |          |    |

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 47.5.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

### 47.5.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 47.5.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 47-110. Ethernet type value examples**

| Type   | Description  |
|--------|--|
| 0x8100 | VLAN-tagged frame. The actual type is found 4 octets later in the frame. |
| 0x0800 | IPv4   |
| 0x0806 | ARP  |
| 0x86DD | IPv6   |

### 47.5.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 47-111. IPv4 header format**

| 31                  | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23              | 22 | 21 | 20 | 19              | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---------------------|----|----|----|----------|----|----|----|-----------------|----|----|----|-----------------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Version             |    |    |    | IHL      |    |    |    | TOS             |    |    |    | Length          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Fragment ID         |    |    |    |          |    |    |    | Flags           |    |    |    | Fragment offset |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| TTL                 |    |    |    | Protocol |    |    |    | Header checksum |    |    |    |                 |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Source address      |    |    |    |          |    |    |    |                 |    |    |    |                 |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |          |    |    |    |                 |    |    |    |                 |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Options             |    |    |    |          |    |    |    |                 |    |    |    |                 |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

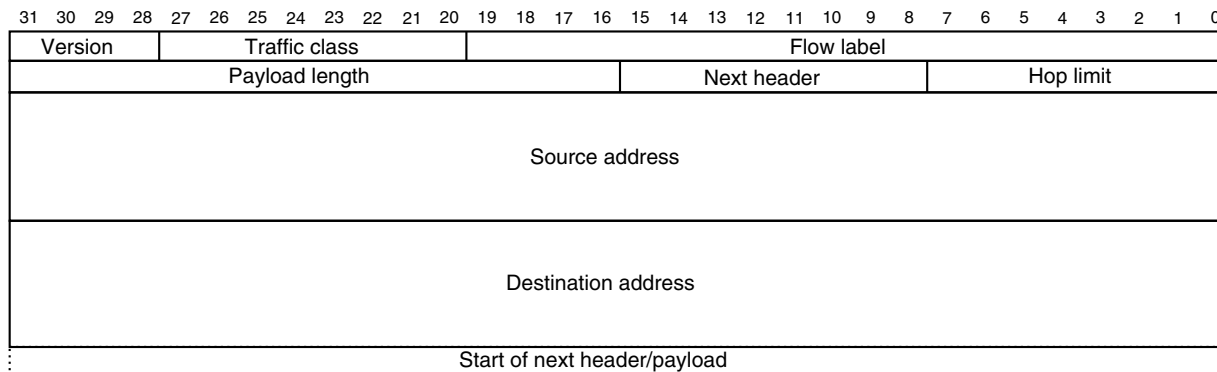

**Table 47-112. IPv4 header fields**

| Field name                          | Description  |
|-------------------------------------|--|
| Version                             | 4-bit IP version information. 0x4 for IPv4 frames.   |
| IHL                                 | 4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5. |
| TOS                                 | Type of service/DiffServ field.  |
| Length                              | Total length of the datagram in bytes, including all octets of header and payload.   |
| Fragment ID, flags, fragment offset | Fields used for IP fragmentation.  |
| TTL                                 | Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.   |
| Protocol                            | Identifier of protocol that follows in the datagram.   |
| Header checksum                     | Checksum of IP header. For computational purposes, this field's value is zero.   |
| Source address                      | Source IP address.   |
| Destination address                 | Destination IP address.  |

### 47.5.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 47-108. IPv6 header format**

**Table 47-113. IPv6 header fields**

| Field name          | Description   |
|---------------------|---|
| Version             | 4-bit IP version information. 0x6 for all IPv6 frames.  |
| Traffic class       | 8-bit field defining the traffic class.   |
| Flow label          | 20-bit flow label identifying frames of the same flow.  |
| Payload length      | 16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.                         |
| Next header         | Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header. |
| Hop limit           | Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.   |
| Source address      | 128-bit IPv6 source address.  |
| Destination address | 128-bit IPv6 destination address.   |

### 47.5.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 47-114. ICMP header format**

|                   |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Type              |    |    |    |    |    |    |    | Code |    |    |    |    |    |    |    | Checksum |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| ICMP message data |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 47-115. IP header fields**

| Field name | Description  |
|------------|--|
| Type       | 8-bit type information   |
| Code       | 8-bit code that is related to the message type                   |
| Checksum   | 16-bit one's complement checksum over the complete ICMP datagram |

### 47.5.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 47-116. UDP header format**

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15               | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source port |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Destination port |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Checksum         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 47-117. UDP header fields**

| Field name       | Description  |
|------------------|--|
| Source port      | Source application port  |
| Destination port | Destination application port   |
| Length           | Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8) |
| Checksum         | Checksum over the complete datagram and some IP header information   |

### 47.5.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 47-118. TCP header format**

|                        |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |
|------------------------|----|----|----|----------|----|----|----|----|----|----|----|-------|----|----|----|------------------|----|----|----|--------|----|---|---|---|---|---|---|---|---|---|---|
| 31                     | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19    | 18 | 17 | 16 | 15               | 14 | 13 | 12 | 11     | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source port            |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    | Destination port |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |
| Sequence number        |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |
| Acknowledgement number |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |
| Offset                 |    |    |    | Reserved |    |    |    |    |    |    |    | Flags |    |    |    |                  |    |    |    | Window |    |   |   |   |   |   |   |   |   |   |   |
| Checksum               |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    | Urgent pointer   |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |
| Options                |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |

**Table 47-119. TCP header fields**

| Field name       | Description   |
|------------------|---|
| Source port      | Source application port   |
| Destination port | Destination application port  |
| Sequence number  | Transmit sequence number  |
| Ack. number      | Receive sequence number   |
| Offset           | Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5 |

*Table continues on the next page...*

**Table 47-119. TCP header fields (continued)**

| Field name | Description   |
|------------|---|
| Flags      | URG, ACK, PSH, RST, SYN, FIN flags  |
| Window     | TCP receive window size information   |
| Checksum   | Checksum over the complete datagram (TCP header and data) and IP header information |
| Options    | Additional 32-bit words for protocol options  |

### 47.5.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 47.5.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 47.5.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 47-120](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 47-120. UDP/IP multicast domains**

| Name                | IP Address  | MAC Address mapping |
|---------------------|-------------|---------------------|
| DefaultPTPdomain    | 224.0.1.129 | 01-00-5E-00-01-81   |
| AlternatePTPdomain1 | 224.0.1.130 | 01-00-5E-00-01-82   |
| AlternatePTPdomain2 | 224.0.1.131 | 01-00-5E-00-01-83   |
| AlternatePTPdomain3 | 224.0.1.132 | 01-00-5E-00-01-84   |

**Table 47-121. UDP port numbers**

| Message type | UDP port | Note  |
|--------------|----------|---|
| Event        | 319      | Used for SYNC and DELAY_REQUEST messages                    |
| General      | 320      | All other messages (for example, follow-up, delay-response) |

### 47.5.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 47-122. PTPv2 multicast domains**

| Name                | MAC address       |
|---------------------|-------------------|
| Normal messages     | 01-1B-19-00-00-00 |
| Peer delay messages | 01-80-C2-00-00-0E |

### 47.5.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

#### 47.5.3.2.1 PTPv1 header

**Table 47-123. Common PTPv1 message header**

| Offset | Octets | Bits                          |   |   |   |   |   |   |   |
|--------|--------|-------------------------------|---|---|---|---|---|---|---|
|        |        | 7                             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0      | 2      | versionPTP = 0x0001           |   |   |   |   |   |   |   |
| 2      | 2      | versionNetwork                |   |   |   |   |   |   |   |
| 4      | 16     | subdomain                     |   |   |   |   |   |   |   |
| 20     | 1      | messageType                   |   |   |   |   |   |   |   |
| 21     | 1      | sourceCommunicationTechnology |   |   |   |   |   |   |   |
| 22     | 6      | sourceUuid                    |   |   |   |   |   |   |   |
| 28     | 2      | sourcePortId                  |   |   |   |   |   |   |   |
| 30     | 2      | sequenceId                    |   |   |   |   |   |   |   |

*Table continues on the next page...*

**Table 47-123. Common PTPv1 message header (continued)**

| Offset | Octets | Bits     |   |   |   |   |   |   |   |
|--------|--------|----------|---|---|---|---|---|---|---|
|        |        | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 32     | 1      | control  |   |   |   |   |   |   |   |
| 33     | 1      | 0x00     |   |   |   |   |   |   |   |
| 34     | 2      | flags    |   |   |   |   |   |   |   |
| 36     | 4      | reserved |   |   |   |   |   |   |   |

The type of message is encoded in the messageType and control fields as shown in [Table 47-124](#) :

**Table 47-124. PTPv1 message type identification**

| messageType | control | Message Name | Message         |
|-------------|---------|--------------|-----------------|
| 0x01        | 0x0     | SYNC         | Event message   |
| 0x01        | 0x1     | DELAY_REQ    | Event message   |
| 0x02        | 0x2     | FOLLOW_UP    | General message |
| 0x02        | 0x3     | DELAY_RESP   | General message |
| 0x02        | 0x4     | MANAGEMENT   | General message |
| other       | other   | —            | Reserved        |

The field sequenceId is used to non-ambiguously identify a message.

### 47.5.3.2.2 PTPv2 header

**Table 47-125. Common PTPv2 message header**

| Offset | Octets | Bits                   |   |   |   |                  |   |   |   |
|--------|--------|------------------------|---|---|---|------------------|---|---|---|
|        |        | 7                      | 6 | 5 | 4 | 3                | 2 | 1 | 0 |
| 0      | 1      | transportSpecific      |   |   |   | messageId        |   |   |   |
| 1      | 1      | reserved               |   |   |   | versionPTP = 0x2 |   |   |   |
| 2      | 2      | messageLength          |   |   |   |                  |   |   |   |
| 4      | 1      | domainNumber           |   |   |   |                  |   |   |   |
| 5      | 1      | reserved               |   |   |   |                  |   |   |   |
| 6      | 2      | flags                  |   |   |   |                  |   |   |   |
| 8      | 8      | correctionField        |   |   |   |                  |   |   |   |
| 16     | 4      | reserved               |   |   |   |                  |   |   |   |
| 20     | 10     | sourcePortIdentity     |   |   |   |                  |   |   |   |
| 30     | 2      | sequenceId             |   |   |   |                  |   |   |   |
| 32     | 1      | control                |   |   |   |                  |   |   |   |
| 33     | 1      | logMeanMessageInterval |   |   |   |                  |   |   |   |

The type of message is encoded in the field `messageId` as follows:

**Table 47-126. PTPv2 message type identification**

| messageId | Message name         | Message         |
|-----------|----------------------|-----------------|
| 0x0       | SYNC                 | Event message   |
| 0x1       | DELAY_REQ            | Event message   |
| 0x2       | PATH_DELAY_REQ       | Event message   |
| 0x3       | PATH_DELAY_RESP      | Event message   |
| 0x4–0x7   | —                    | Reserved        |
| 0x8       | FOLLOW_UP            | General message |
| 0x9       | DELAY_RESP           | General message |
| 0xa       | PATH_DELAY_FOLLOW_UP | General message |
| 0xb       | ANNOUNCE             | General message |
| 0xc       | SIGNALING            | General message |
| 0xd       | MANAGEMENT           | General message |

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 47-127. PTPv2 message flags field definitions**

| Bit | Name             | Description   |
|-----|------------------|---|
| 0   | ALTERNATE_MASTER | See IEEE 1588 Clause 17.4   |
| 1   | TWO_STEP         | 1 Two-step clock<br>0 One-step clock  |
| 2   | UNICAST          | 1 Transport layer address uses a unicast destination address<br>0 Multicast is used |
| 3   | —                | Reserved  |
| 4   | —                | Reserved  |
| 5   | Profile specific |   |
| 6   | Profile specific |   |
| 7   | —                | Reserved  |

## 47.5.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

**functional description**

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

**Figure 47-109. MAC receive flow**

### 47.5.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

### 47.5.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100 Mbps operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 47.5.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 47.5.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $\text{RCR}[\text{PROM}] = 1$ ) no address checking is performed and all unicast frames are accepted.

#### 47.5.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $\text{ENET}_n\_GAUR/GALR$  (group address hash match) or  $\text{ENET}_n\_IAUR/IALR$  (individual address hash match).

**functional description**

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET $n$ \_GAUR (msb = 1) or ENET $n$ \_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled (ENET $n$ \_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET $n$ \_GAUR/GALR and ENET $n$ \_IAUR/IALR settings.

**47.5.4.3.3 Broadcast address reject**

All broadcast frames are accepted if BC\_REJ is cleared or ENET $n$ \_RCR[PROM] is set. If PROM is cleared when ENET $n$ \_RCR[BC\_REJ] is set, all broadcast frames are rejected.

**Table 47-128. Broadcast address reject programming**

| PROM | BC_REJ | Broadcast frames |
|------|--------|------------------|
| 0    | 0      | Accepted         |
| 0    | 1      | Rejected         |
| 1    | 0      | Accepted         |
| 1    | 1      | Accepted         |

#### 47.5.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC\_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 47.5.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 47.5.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET<sub>n</sub>\_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

### 47.5.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxB<sub>BD</sub>[NO]) indicates that the current frame is VLAN tagged.

### 47.5.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET<sub>n</sub>\_RCR[FCE] is cleared and are forwarded to the client interface when ENET<sub>n</sub>\_RCR[PAUFWD] is set.

### 47.5.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET<sub>n</sub>\_RCR[CRCFWD] is cleared and ENET<sub>n</sub>\_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and RxB<sub>BD</sub>[CR] is set.

### 47.5.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

### 47.5.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

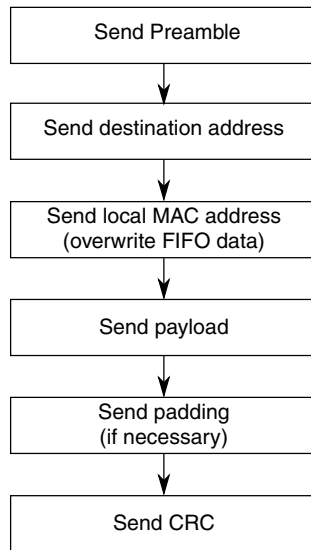

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if `ENETn_TCR[TFC_PAUSE]` is set with `ENETn_OPD[PAUSE_DUR]` set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if `TFC_PAUSE` is set with `PAUSE_DUR` cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 47-110. Frame transmit overview**

### 47.5.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

### 47.5.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET $n$ \_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET $n$ \_TCR[ADDINS] = 0)

### 47.5.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

### 47.5.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in  $ENETn\_TIPG$ ) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

### 47.5.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

**Figure 47-111. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

## 47.5.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

### 47.5.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

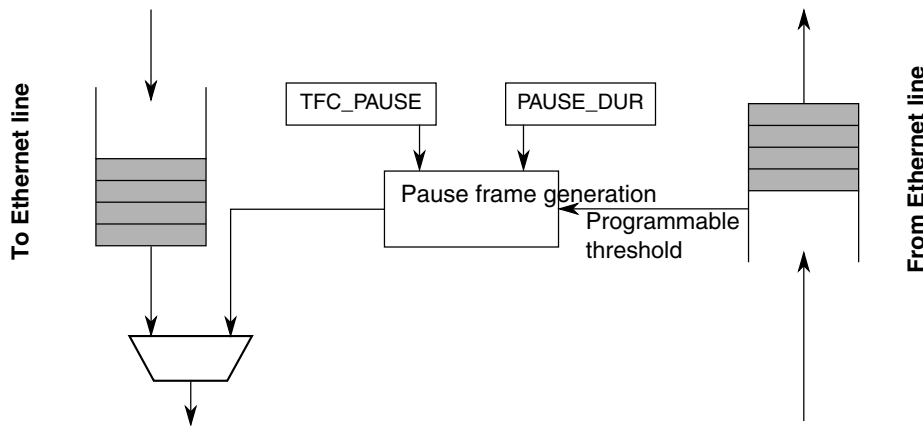

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

### 47.5.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET $n$ \_TCR[TFC\_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC\_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET $n$ \_OPD[PAUSE\_DUR].

**Figure 47-112. Pause frame generation overview**

**Note**

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

**47.5.7 Magic packet detection**

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

### 47.5.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET $n$ \_ECR[SLEEP]. At the same time ENET $n$ \_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET $n$ \_ECR register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

### 47.5.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

### 47.5.7.3 Wakeup

When a magic packet is detected, indicated by ENET $n$ \_EIR[WAKEUP], ENET $n$ \_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET $n$ \_ECR[MAGICEN], disabling magic packet detection.

## 47.5.8 IP accelerator functions

The following sections describe the IP accelerator functions.

### 47.5.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 47-129. IPv4 pseudo-header for checksum calculation**

|                     |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|----------|----|----|----|----|----|----|----|----------------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19             | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Zero                |    |    |    | Protocol |    |    |    |    |    |    |    | TCP/UDP length |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 47-130. IPv6 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| TCP/UDP length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Next header |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 47.5.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 47.5.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $_n$ \_TACC and ENET $_n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 47-131](#).

**Table 47-131. 64-bit interface data structure with SHIFT16 enabled**

|         |    |         |         |         |        |        |           |           |
|---------|----|---------|---------|---------|--------|--------|-----------|-----------|
| 63      | 56 | 55 48   | 47 40   | 39 32   | 31 24  | 23 16  | 15 8      | 7 0       |
| Byte 5  |    | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 | Any value | Any value |
| Byte 13 |    | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 | Byte 7    | Byte 6    |
| ...     |    |         |         |         |        |        |           |           |

#### 47.5.8.3.1 Receive processing

When ENET $_n$ \_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

## Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 47.5.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 47.5.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (`ENETn_RACC`), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 47.5.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

#### Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 47.5.8.6 IPv6 support

The following sections describe the IPv6 support.

#### 47.5.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

#### 47.5.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

### 47.5.9 Resets and stop controls

The following sections describe the resets and stop controls.

#### 47.5.9.1 Hardware reset

To reset the Ethernet module, set ENET $n$ \_ECR[RESET].

#### 47.5.9.2 Soft reset

When ENET $n$ \_ECR[ETHER\_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.

- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 47.5.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 47.5.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER\_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 47.5.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

## functional description

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

### 47.5.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set

- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

### Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

#### 47.5.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

## 47.5.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET $n$ \_ECR[EN1588] to enable 1588 support.

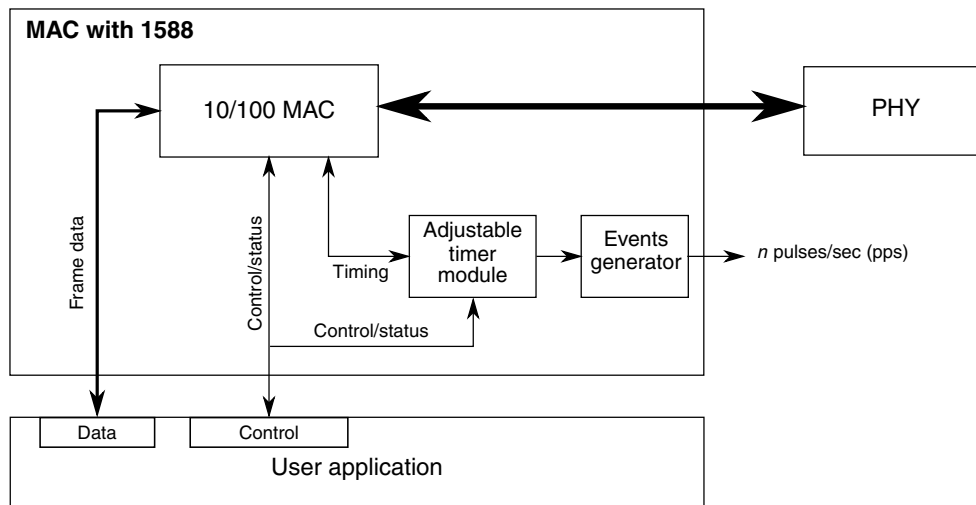

Figure 47-113. IEEE 1588 functions overview

### 47.5.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 47.5.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

**Figure 47-114. Adjustable timer implementation detail**

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in  $ENET_n\_ATINC$ . The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in  $ENET_n\_ATPER$ , defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(Current + Inc - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in  $ENET_n\_ATCOR$ , it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in  $ENET_n\_ATINC$ . To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode ( $ENET_n\_ATCR[SLAVE] = 1$ ), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET $n$ _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

### 47.5.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET $n$ _ATSTMP`. `ENET $n$ _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET $n$ _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET $n$ _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

### 47.5.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

### 47.5.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

## 47.5.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

### 47.5.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

### 47.5.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

### 47.5.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSR_n[TDRE]$ . The corresponding DMA request is generated when the  $TCSR_n[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSR_n[TF]$  flag is cleared.

## 47.5.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

## functional description

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

### 47.5.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

**Table 47-132. Receive FIFO thresholds definition**

| Register                                 | Description  |
|--|--|
| ENET $n$ _RSFL<br>[RX_SECTION_F<br>ULL]  | <p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p> |
| ENET $n$ _RAEM<br>[RX_ALMOST_E<br>MPTY]  | <p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>  |
| ENET $n$ _RAFL<br>[RX_ALMOST_F<br>ULL]   | <p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p> <p>The corresponding error status is set when the frame is delivered to the application.</p> <p>Set ENET<math>n</math>_RAFL to a minimum of 4.</p>   |
| ENET $n$ _RSEM<br>[RX_SECTION_E<br>MPTY] | <p>When the FIFO level reaches the ENET<math>n</math>_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.</p> <p>When the FIFO level goes below the value programmed in ENET<math>n</math>_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.</p> <p>Clearing ENET<math>n</math>_RSEM disables any pause frame generation.</p>  |

Figure 47-115. Receive FIFO overview

### 47.5.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 47-133. Transmit FIFO thresholds definition

| Register                                      | Description  |
|---|--|
| ENET <sub>n</sub> _TAEM<br>[TX_ALMOST_EMPTY]  | When the FIFO level reaches the ENET <sub>n</sub> _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.<br>Set ENET <sub>n</sub> _TAEM to a minimum of 4.  |
| ENET <sub>n</sub> _TAFL<br>[TX_ALMOST_FULL]   | When the FIFO level approaches the maximum, so that there is no more space for at least ENET <sub>n</sub> _TAFL number of words, the MAC deasserts its control signal to the application.<br>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.<br>Set ENET <sub>n</sub> _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion. |
| ENET <sub>n</sub> _TSEM<br>[TX_SECTION_EMPTY] | When the FIFO level reaches the ENET <sub>n</sub> _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.<br>When ENET <sub>n</sub> _TSEM is 0, the signal is never deasserted.  |

Table continues on the next page...

**Table 47-133. Transmit FIFO thresholds definition (continued)**

| Register                | Description   |
|-------------------------|---|
| ENET <sub>n</sub> _TFWR | <p>When the FIFO level reaches the ENET<sub>n</sub>_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).</p> <p>If a complete frame has a size smaller than the ENET<sub>n</sub>_TFWR threshold, the MAC also transmits the frame to the line.</p> <p>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.</p> |

**Figure 47-116. Transmit FIFO overview**

## 47.5.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET<sub>n</sub>\_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET<sub>n</sub>\_RCR register fields:

**Table 47-134. Loopback options**

| Register field | Description   |
|----------------|---|
| LOOP           | <p>Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.</p> <p>In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))</p> |

**Figure 47-117. Loopback options**

### 47.5.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET $n$ \_ECR[1588EN].

#### NOTE

- The legacy buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

#### 47.5.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 47-138](#) contains the descriptions for each field.

**Table 47-135. Legacy FEC receive buffer descriptor (RxBD)**

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|--|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3 | 2  | 1  | 0  |
| Offset + 0 | Data length                            |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |
| Offset + 2 | E                                      | RO1 | W  | RO2 | L  | —  | — | M | BC     | MC | LG | NO | — | CR | OV | TR |
| Offset + 4 | Rx data buffer pointer — low halfword  |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |
| Offset + 6 | Rx data buffer pointer — high halfword |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |

### 47.5.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 47-140](#) contains the descriptions for each field.

**Table 47-136. Legacy FEC transmit buffer descriptor (TxBD)**

|            | Byte 1                                 |     |    |     |    |    |                  |   | Byte 0 |   |   |   |   |   |   |   |
|------------|--|-----|----|-----|----|----|------------------|---|--------|---|---|---|---|---|---|---|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9                | 8 | 7      | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Offset + 0 | Data Length                            |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |
| Offset + 2 | R                                      | TO1 | W  | TO2 | L  | TC | ABC <sup>1</sup> | — | —      | — | — | — | — | — | — | — |
| Offset + 4 | Tx Data Buffer Pointer — low halfword  |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |
| Offset + 6 | Tx Data Buffer Pointer — high halfword |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |

1. This field is not supported by the uDMA.

## 47.5.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET<sub>n</sub>\_ECR[1588EN].

### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

### 47.5.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 47-138](#) contains the descriptions for each field.

**Table 47-137. Enhanced uDMA receive buffer descriptor (RxBD)**

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|--|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3 | 2  | 1  | 0  |
| Offset + 0 | Data length                            |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |
| Offset + 2 | E                                      | RO1 | W  | RO2 | L  | —  | — | M | BC     | MC | LG | NO | — | CR | OV | TR |
| Offset + 4 | Rx data buffer pointer – low halfword  |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |
| Offset + 6 | Rx data buffer pointer – high halfword |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |

*Table continues on the next page...*

**Table 47-137. Enhanced uDMA receive buffer descriptor (RxBD) (continued)**

|             |                                |   |   |   |   |   |    |    |    |     |   |               |   |   |   |   |   |   |   |     |     |   |      |      |     |

**Table 47-138. Receive buffer descriptor field definitions**

| Word       | Field               | Description  |
|------------|---------------------|--|
| Offset + 0 | 15–0<br>Data Length | Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed. |
| Offset + 2 | 15<br>E             | Empty. Written by the MAC (= 0) and user (= 1).  |
|            |                     | 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required.   |
|            |                     | 1 The data buffer associated with this BD is empty, or reception is currently in progress.   |
| Offset + 2 | 14<br>RO1           | Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.   |
| Offset + 2 | 13<br>W             | Wrap. Written by user.   |
|            |                     | 0 The next buffer descriptor is found in the consecutive location.<br>1 The next buffer descriptor is found at the location defined in ENET <sub>n</sub> _RDSR.  |
| Offset + 2 | 12<br>RO2           | Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.   |
| Offset + 2 | 11<br>L             | Last in frame. Written by the uDMA.  |
|            |                     | 0 The buffer is not the last in a frame.   |
|            |                     | 1 The buffer is the last in a frame.   |
| Offset + 2 | 10–9                | Reserved, must be cleared.   |

Table continues on the next page...

**Table 47-138. Receive buffer descriptor field definitions (continued)**

| Word       | Field                            | Description   |
|------------|----------------------------------|---|
| Offset + 2 | 8<br>M                           | Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. |
|            |                                  | 0 The frame was received because of an address recognition hit.   |
|            |                                  | 1 The frame was received because of promiscuous mode.   |
|            |                                  | The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.  |
| Offset + 2 | 7<br>BC                          | Set if the DA is broadcast (FFFF_FFFF_FFFF).  |
| Offset + 2 | 6<br>MC                          | Set if the DA is multicast and not BC.  |
| Offset + 2 | 5<br>LG                          | Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.  |
| Offset + 2 | 4<br>NO                          | Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.                   |
| Offset + 2 | 3                                | Reserved, must be cleared.  |
| Offset + 2 | 2<br>CR                          | Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.   |
| Offset + 2 | 1<br>OV                          | Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, CR, and CL, lose their normal meaning and are zero. This field is valid only if the L field is set.   |
| Offset + 2 | 0<br>TR                          | Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.   |
| Offset + 4 | 15–0<br>Data buffer pointer low  | Receive data buffer pointer, low halfword   |
| Offset + 6 | 15–0<br>Data buffer pointer high | Receive data buffer pointer, high halfword <sup>1</sup>   |
| Offset + 8 | 15–13<br>VPCP                    | VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.   |
| Offset + 8 | 12–6                             | Reserved, must be cleared.  |
| Offset + 8 | 5<br>ICE                         | IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.                                      |
| Offset + 8 | 4<br>PCR                         | Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.  |

Table continues on the next page...

**Table 47-138. Receive buffer descriptor field definitions (continued)**

| Word        | Field                    | Description  |
|-------------|--------------------------|--|
| Offset + 8  | 3                        | Reserved, must be cleared.   |
| Offset + 8  | 2<br>VLAN                | VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.  |
| Offset + 8  | 1<br>IPV6                | IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.  |
| Offset + 8  | 0<br>FRAG                | IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.  |
| Offset + A  | 15<br>ME                 | MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.   |
| Offset + A  | 14–11                    | Reserved, must be cleared.   |
| Offset + A  | 10<br>PE                 | PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.   |
| Offset + A  | 9<br>CE                  | Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.   |
| Offset + A  | 8<br>UC                  | Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.   |
| Offset + A  | 7<br>INT                 | Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .   |
| Offset + A  | 6–0                      | Reserved, must be cleared.   |
| Offset + C  | 15–0<br>Payload checksum | Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.  |
| Offset + E  | 15–11<br>Header length   | Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set. |
| Offset + E  | 10–8                     | Reserved, must be cleared.   |
| Offset + E  | 7–0<br>Protocol type     | Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.  |
| Offset + 10 | 15–0                     | Reserved, must be cleared.   |
| Offset + 12 | 15<br>BDU                | Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).  |

Table continues on the next page...

**Table 47-138. Receive buffer descriptor field definitions (continued)**

| Word        | Field          | Description  |
|-------------|----------------|--|
| Offset + 12 | 14–0           | Reserved, must be cleared.   |
| Offset + 14 | 15–0           | This value is written by the uDMA. It is only valid if the L field is set. |
| Offset + 16 | 1588 timestamp |  |
| Offset + 18 | 15–0           | Reserved, must be cleared.   |
| –           |                |  |
| Offset + 1E |                |  |

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

### 47.5.14.2 Enhanced transmit buffer descriptor

**Table 47-139. Enhanced transmit buffer descriptor (TxBD)**

|             | Byte 1                                 |     |    |      |      |     |    |     | Byte 0 |   |   |   |   |   |   |   |
|-------------|--|-----|----|------|------|-----|----|-----|--------|---|---|---|---|---|---|---|
|             | 15                                     | 14  | 13 | 12   | 11   | 10  | 9  | 8   | 7      | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Offset + 0  | Data length                            |     |    |      |      |     |    |     |        |   |   |   |   |   |   |   |
| Offset + 2  | R                                      | TO1 | W  | TO2  | L    | TC  | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + 4  | Tx Data Buffer Pointer – low halfword  |     |    |      |      |     |    |     |        |   |   |   |   |   |   |   |
| Offset + 6  | Tx Data Buffer Pointer – high halfword |     |    |      |      |     |    |     |        |   |   |   |   |   |   |   |
| Offset + 8  | TXE                                    | —   | UE | EE   | FE   | LCE | OE | TSE | —      | — | — | — | — | — | — | — |
| Offset + A  | —                                      | INT | TS | PINS | IINS | —   | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + C  | —                                      | —   | —  | —    | —    | —   | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + E  | —                                      | —   | —  | —    | —    | —   | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + 10 | —                                      | —   | —  | —    | —    | —   | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + 12 | BDU                                    | —   | —  | —    | —    | —   | —  | —   | —      | — | — | — | — | — | — | — |
| Offset + 14 | 1588 timestamp – low halfword          |     |    |      |      |     |    |     |        |   |   |   |   |   |   |   |
| Offset + 16 | 1588 timestamp – high halfword         |     |    |      |      |     |    |     |        |   |   |   |   |   |   |   |
| Offset + 18 | —                                      | —   | —  | —    | —    | —   | —  | —   | —      | — | — | — | — | — | — | — |

**Table 47-140. Enhanced transmit buffer descriptor field definitions**

| Word       | Field       | Description  |
|------------|-------------|--|
| Offset + 0 | 15–0        | Data length, written by user.  |
|            | Data Length | Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC. |

*Table continues on the next page...*

**Table 47-140. Enhanced transmit buffer descriptor field definitions (continued)**

| Word  | Field  | Description  |   |  |   |   |
|---|--|--|---|--|---|---|
| Offset + 2  | 15<br>R  | Ready. Written by the MAC and you.   |   |  |   |   |
|   |  | <table border="1"> <tr> <td>0</td> <td>The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered.</td> </tr> <tr> <td>1</td> <td>The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.</td> </tr> </table> | 0   | The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. | 1 | The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set. |
| 0   | The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. |  |   |  |   |   |
| 1   | The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.  |  |   |  |   |   |
| Offset + 2  | 14<br>TO1  | Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.  |   |  |   |   |
| Offset + 2  | 13<br>W  | Wrap. Written by user.   |   |  |   |   |
|   |  | <table border="1"> <tr> <td>0</td> <td>The next buffer descriptor is found in the consecutive location</td> </tr> <tr> <td>1</td> <td>The next buffer descriptor is found at the location defined in ETDSR.</td> </tr> </table>  | 0   | The next buffer descriptor is found in the consecutive location  | 1 | The next buffer descriptor is found at the location defined in ETDSR.   |
| 0   | The next buffer descriptor is found in the consecutive location  |  |   |  |   |   |
| 1   | The next buffer descriptor is found at the location defined in ETDSR.  |  |   |  |   |   |
| Offset + 2  | 12<br>TO2  | Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.   |   |  |   |   |
| Offset + 2  | 11<br>L  | Last in frame. Written by user.  |   |  |   |   |
|   |  | <table border="1"> <tr> <td>0</td> <td>The buffer is not the last in the transmit frame</td> </tr> <tr> <td>1</td> <td>The buffer is the last in the transmit frame</td> </tr> </table>  | 0   | The buffer is not the last in the transmit frame   | 1 | The buffer is the last in the transmit frame  |
| 0   | The buffer is not the last in the transmit frame   |  |   |  |   |   |
| 1   | The buffer is the last in the transmit frame   |  |   |  |   |   |
| Offset + 2  | 10<br>TC   | Transmit CRC. Written by user, and valid only when L is set.   |   |  |   |   |
|   |  | <table border="1"> <tr> <td>0</td> <td>End transmission immediately after the last data byte</td> </tr> <tr> <td>1</td> <td>Transmit the CRC sequence after the last data byte</td> </tr> </table>   | 0   | End transmission immediately after the last data byte  | 1 | Transmit the CRC sequence after the last data byte  |
|   |  | 0  | End transmission immediately after the last data byte |  |   |   |
| 1   | Transmit the CRC sequence after the last data byte   |  |   |  |   |   |
| This field is valid only when the L field is set. |  |  |   |  |   |   |
| Offset + 2  | 9<br>ABC   | Append bad CRC.<br><b>Note:</b> This field is not supported by the uDMA and is ignored.  |   |  |   |   |
| Offset + 2  | 8–0  | Reserved, must be cleared.   |   |  |   |   |
| Offset + 4  | 15–0<br>Data buffer pointer low  | Tx data buffer pointer, low halfword   |   |  |   |   |
| Offset + 6  | 15–0<br>Data buffer pointer high   | Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.   |   |  |   |   |
| Offset + 8  | 15<br>TXE  | Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.   |   |  |   |   |
| Offset + 8  | 14   | Reserved, must be cleared.   |   |  |   |   |
| Offset + 8  | 13<br>UE   | Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.   |   |  |   |   |
| Offset + 8  | 12<br>EE   | Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.   |   |  |   |   |

Table continues on the next page...

**Table 47-140. Enhanced transmit buffer descriptor field definitions (continued)**

| Word                    | Field          | Description   |
|-------------------------|----------------|---|
| Offset + 8              | 11<br>FE       | Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.  |
| Offset + 8              | 10<br>LCE      | Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.  |
| Offset + 8              | 9<br>OE        | Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.   |
| Offset + 8              | 8<br>TSE       | Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.   |
| Offset + 8              | 7–0            | Reserved, must be cleared.  |
| Offset + A              | 15             | Reserved, must be cleared.  |
| Offset + A              | 14<br>INT      | Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.   |
| Offset + A              | 13<br>TS       | Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.  |
| Offset + A              | 12<br>PINS     | Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame. |
| Offset + A              | 11<br>IINS     | Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.          |
| Offset + A              | 10–0           | Reserved, must be cleared.  |
| Offset + C              | 15–0           | Reserved, must be cleared.  |
| Offset + E              | 15–0           | Reserved, must be cleared.  |
| Offset + 10             | 15–0           | Reserved, must be cleared.  |
| Offset + 12             | 15<br>BDU      | Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).   |
| Offset + 12             | 14–0           | Reserved, must be cleared.  |
| Offset + 14             | 15–0           | This value is written by the uDMA . It is valid only when the L field is set.   |
| Offset + 16             | 1588 timestamp |   |
| Offset + 18–Offset + 1E | 15–0           | Reserved, must be cleared.  |

## 47.5.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

### 47.5.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 47-141. FIFO interface data structure**

|        | 63      | 56 55   | 48 47   | 40 39   | 32 31   | 24 23   | 16 15  | 8 7    | 0 |
|--------|---------|---------|---------|---------|---------|---------|--------|--------|---|
| Word 0 | Byte 7  | Byte 6  | Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 |   |
| Word 1 | Byte 15 | Byte 14 | Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 |   |
| ...    | ...     |         |         |         |         |         |        |        |   |

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

**Note**

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 47-142. FIFO interface frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–13       | Length/type field       |
| 14–N        | Payload data            |

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 47-143. FIFO interface VLAN frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–15       | VLAN tag and info       |
| 16–17       | Length/type field       |
| 18–N        | Payload data            |

**Note**

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

### 47.5.15.2 Data structure examples

**Figure 47-118. Normal Ethernet frame 64-bit mapping example**

**Figure 47-119. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 47.5.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

## 47.5.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

### 47.5.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in Figure 47-120) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 47-120. Transmit FIFO underflow protection

### 47.5.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

#### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $_n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

### 47.5.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 47-121. Receive FIFO overflow protection

## 47.5.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

| Ethernet speed mode | Ethernet bus clock | Minimum ENET system clock |
|---------------------|--------------------|---------------------------|
| 10 Mbps             | 2.5 MHz            | 5 MHz                     |
| 100 Mbps            | 25.0 MHz           | 50 MHz                    |

## 47.5.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

### 47.5.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 47-144. MDIO clause 22 frame structure**

|    |    |        |        |    |      |
|----|----|--------|--------|----|------|
| ST | OP | PHYADR | REGADR | TA | DATA |
|----|----|--------|--------|----|------|

**Table 47-145. MDIO frame field descriptions**

| Field          | Description   |
|----------------|---|
| ST<br>(2 bits) | Start indication field, programmed with ENETn_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22). |

*Table continues on the next page...*

**Table 47-145. MDIO frame field descriptions (continued)**

| Field              | Description  |
|--------------------|--|
| OP<br>(2 bits)     | Opcode defines type of operation. Programmed with ENET $n$ _MMFR[OP].<br>01 Write operation<br>10 Read operation   |
| PHYADR<br>(5 bits) | Five-bit PHY device address, programmed with ENET $n$ _MMFR[PA]. Up to 32 devices can be addressed.  |
| REGADR<br>(5 bits) | Five-bit register address, programmed with ENET $n$ _MMFR[RA]. Each PHY can implement up to 32 registers.  |
| TA<br>(2 bits)     | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| Data<br>(16 bits)  | Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY   |

### 47.5.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 47-146. MDIO clause 45 frame structure**

| ST | OP | PRTAD | DEVAD | TA | ADDR/DATA |
|----|----|-------|-------|----|-----------|
|----|----|-------|-------|----|-----------|

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 47-147. MDIO clause 45 frame field descriptions**

| Field | Description  |
|-------|--|
| ST    | Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames. |

*Table continues on the next page...*

**Table 47-147. MDIO clause 45 frame field descriptions (continued)**

| Field     | Description   |
|-----------|---|
| OP        | Opcode defines if a read or write operation is performed and is programmed with ENET <sub>n</sub> _MMFR[OP]. See <a href="#">Table 47-148</a> for more information.<br>00 Address write<br>01 Write operation<br>10 Read inc. operation<br>11 Read operation                            |
| PRTAD     | The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.  |
| DEVAD     | Device address. Up to 32 devices can be addressed (within a port).  |
| TA        | Turnaround time, programmed with ENET <sub>n</sub> _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| ADDR/DATA | 16-bit address (for address write) or data, set by ENET <sub>n</sub> _MMFR[DATA], written to or read from the PHY.  |

**Table 47-148. MDIO Clause 45 Transactions**

| Transaction Type | Description  |
|------------------|--|
| Address          | A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.   |
| Write            | Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.   |
| Read             | Data is read from the register identified by the device-internal address.  |
| Read inc.        | Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around). |

### 47.5.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock divided by the value programmed in ENET<sub>n</sub>\_MSCR[MII\_SPEED].

### 47.5.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

Figure 47-122. MDIO access overview

## 47.5.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

| Mode              | ECR[SLEEP] | RCR[RMII_10T] | RCR[RMII_MODE] |
|-------------------|------------|---------------|----------------|
| MII - 10 Mbit/s   | 0          | —             | 0              |
| MII - 100 Mbit/s  | 0          | —             | 0              |
| RMII - 10 Mbit/s  | 0          | 1             | 1              |
| RMII - 100 Mbit/s | 0          | 0             | 1              |

### 47.5.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

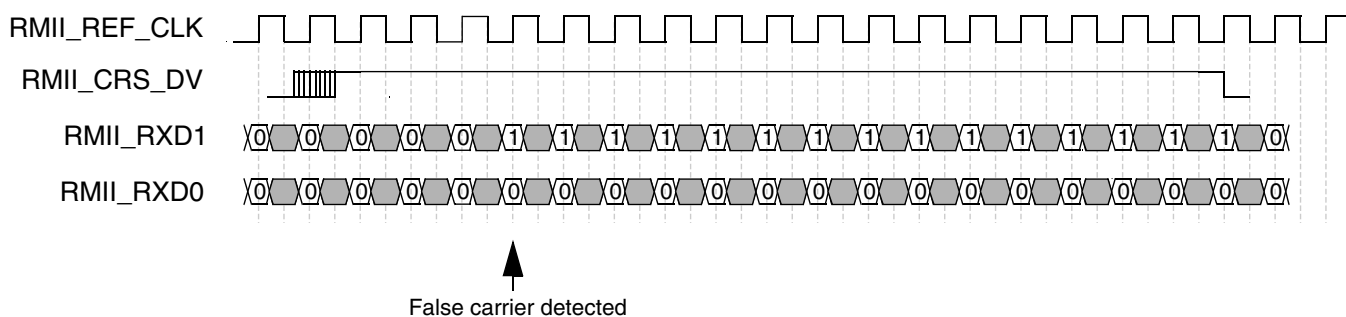

functional description

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

**Figure 47-123. RMIi receive operation**

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 47-124. RMIi receive operation with false carrier**

In RMIi transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

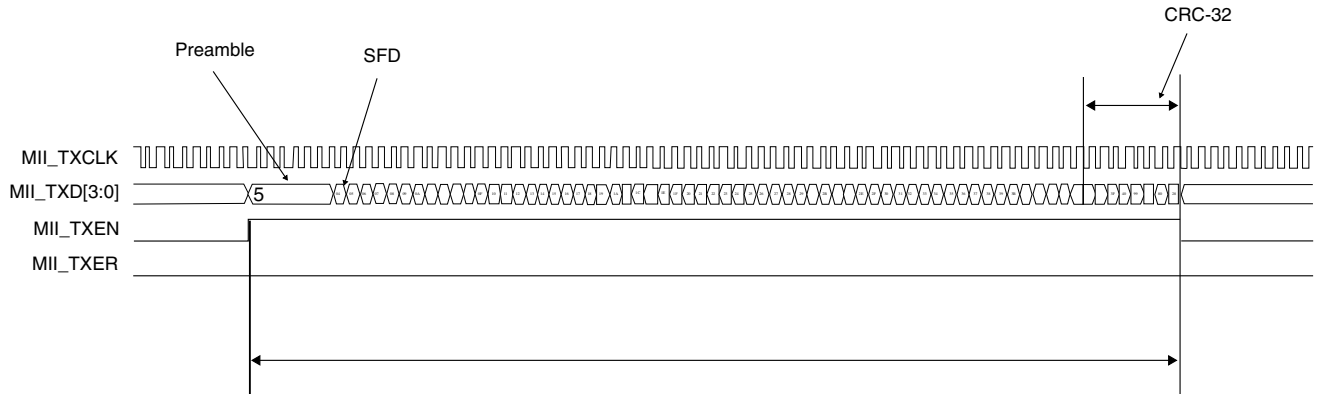

**Figure 47-125. RMIi transmit operation**

### 47.5.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 47-126. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 47-127. MII transmit operation — errored frame**

### 47.5.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

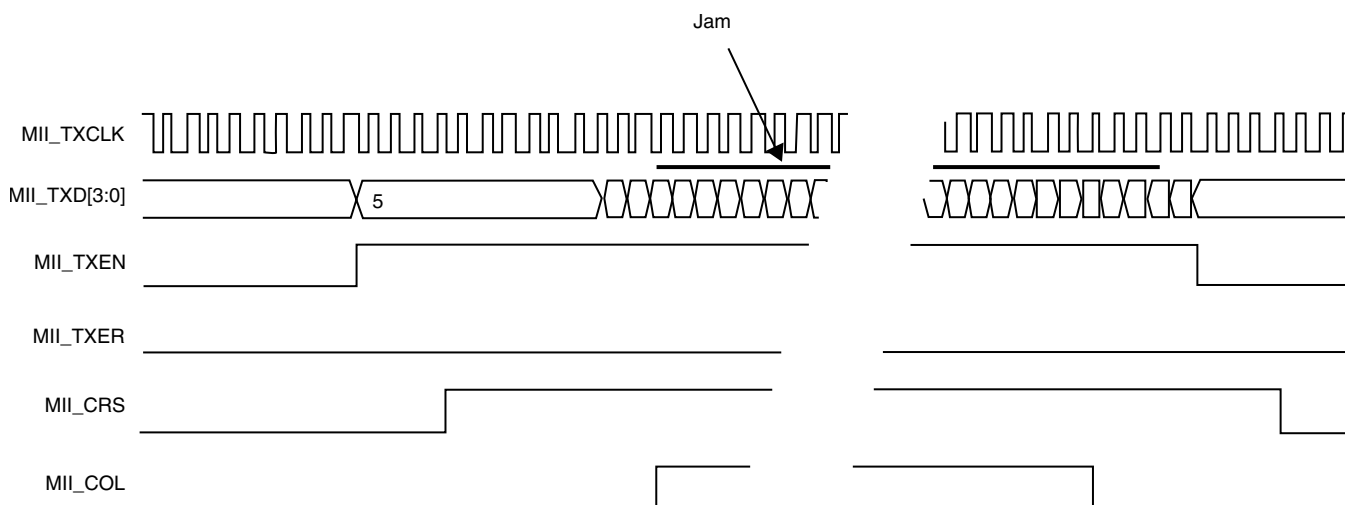

Figure 47-128. MII transmit operation — transmission with collision

### 47.5.19.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 47-129. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 47-130. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

# Chapter 48

## Universal Serial Bus Full Speed OTG Controller (USBFSOTG)

### 48.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes the USB full speed OTG controller. The OTG implementation in this module provides limited host functionality and device solutions for implementing a USB 2.0 full-speed/low-speed compliant peripheral. The OTG implementation supports the On-The-Go (OTG) addendum to the USB 2.0 Specification. The USB full speed controller interfaces to a USBFS/LS transceiver.

#### NOTE

This chapter describes the following registers that have similar names: USB\_OTGCTL, USB\_CTL, USB\_CTRL, and USB\_CONTROL. These are all separate registers.

#### 48.1.1 USB

The USB is a cable bus that supports data exchange between a host computer and a wide range of simultaneously accessible peripherals. The attached peripherals share USB bandwidth through a host-scheduled, token-based protocol. The bus allows peripherals to be attached, configured, used, and detached while the host and other peripherals are in operation.

USB software provides a uniform view of the system for all application software, hiding implementation details making application software more portable. It manages the dynamic attach and detach of peripherals.

There is only one host in any USB system. The USB interface to the host computer system is referred to as the Host Controller.

There may be multiple USB devices in any system such as joysticks, speakers, printers, etc. USB devices present a standard USB interface in terms of comprehension, response, and standard capability.

The host initiates transactions to specific peripherals, whereas the device responds to control transactions. The device sends and receives data to and from the host using a standard USB data format. USB 2.0 full-speed /low-speed peripherals operate at 12Mbit/s or 1.5 Mbit/s.

For additional information, see the USB 2.0 specification.

**Figure 48-1. Example USB 2.0 system configuration**

## 48.1.2 USB On-The-Go

USB is a popular standard for connecting peripherals and portable consumer electronic devices such as digital cameras and tablets to host PCs. The On-The-Go (OTG) Supplement to the USB Specification extends USB to peer-to-peer application. Using USB OTG technology, consumer electronics, peripherals, and portable devices can connect to each other to exchange data. For example, a digital camera can connect directly to a printer, or a keyboard can connect to a tablet to exchange data.

With the USB On-The-Go product, you can develop a fully USB-compliant peripheral device that can also assume the role of a USB host. Software determines the role of the device based on hardware signals, and then initializes the device in the appropriate mode

of operation (host or peripheral) based on how it is connected. After connecting, the devices can negotiate using the OTG protocols to assume the role of host or peripheral based on the task to be accomplished.

For additional information, see the *On-The-Go Supplement to the USB 2.0 Specification*.

**Figure 48-2. Example USB 2.0 On-The-Go configurations**

### 48.1.3 USBFS Features

- USB 1.1 and 2.0 compliant full-speed device controller
- 16 bidirectional end points
- DMA or FIFO data stream interfaces
- Low-power consumption
- On-The-Go protocol logic

## 48.2 Functional description

USBOTG communicates with the processor core through status registers, control registers, and data structures in memory.

## 48.2.1 Data Structures

To efficiently manage USB endpoint communications, USBFS implements a Buffer Descriptor Table (BDT) in system memory. See [Figure 48-6](#).

## 48.2.2 On-chip transceiver required external components

USB system operation requires external components to ensure that driver output impedance, eye diagram, and VBUS cable fault tolerance requirements are met. DM and DP I/O pads must connect through series resistors (approximately 33  $\Omega$  each) to the USB connector on the application printed circuit board (PCB). Additionally, signal quality optimizes when these 33  $\Omega$  resistors are mounted closer to the processor than to the USB board-level connector. The USB transceiver includes:

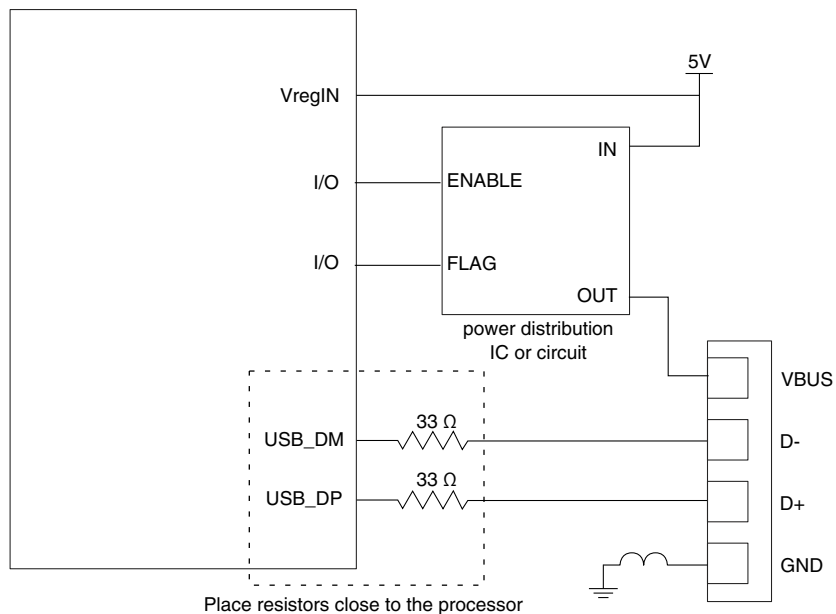

- An internal 1.5 k $\Omega$  pullup resistor on the USB\_DP line for full-speed device (controlled by USB\_CONTROL[DPPULLUPNONOTG] or USB\_OTGCTL[DPHIGH])
- Internal 15 k $\Omega$  pulldown resistors on the USB\_DP and USB\_DM signals, which keep the DP and DM ports in a known quiescent state when the USB port is not used or when a USB cable is not connected.

### NOTE

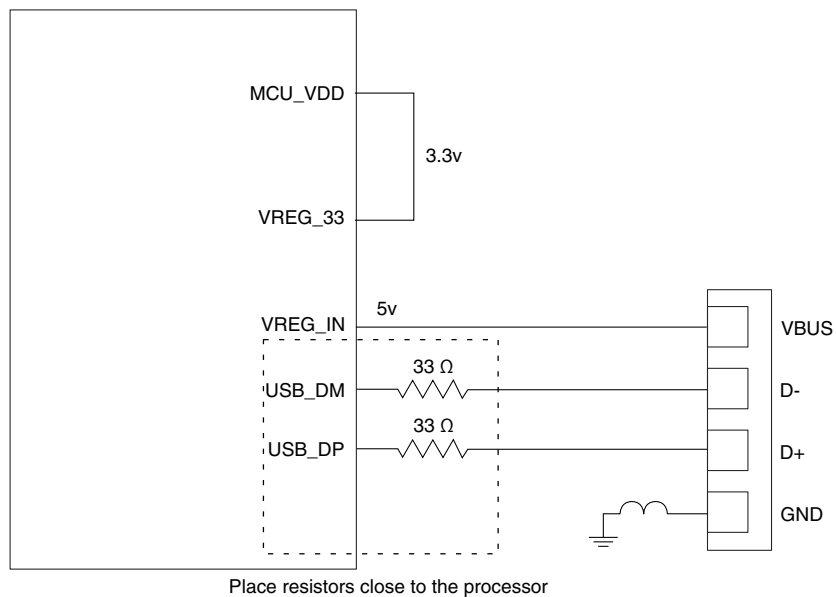

For device operation, the internal 15 k $\Omega$  pulldowns should be enabled when the VBUS detection software determines that the USB connection is not activated, including the case when no cable to a host is present. The internal 15 k $\Omega$  pulldowns should be controlled by USB\_CTRL[PDE] in this case.

For host operation, the internal 15 k $\Omega$  pulldowns are enabled automatically, as required by the USB 2.0 specification, when USB\_CTL[HOSTMODEEN] is asserted high.

The following diagrams provide overviews of host-only, device-only, and dual-role connections, respectively. For more details, see the *Kinetis Peripheral Module Quick Reference*(KQRUG).

**Figure 48-3. Host-only diagram**

**Figure 48-4. Typical Device-only block diagram (bus-powered)**

Figure 48-5. Dual-role diagram

## 48.3 Programmers interface

This section discusses the major components of the programming model for the USB module.

### 48.3.1 Buffer Descriptor Table

To efficiently manage USB endpoint communications USBFS implements a Buffer Descriptor Table (BDT) in system memory. The BDT resides on a 512-byte boundary in system memory and is pointed to by the BDT Page Registers. Every endpoint direction requires two 8-byte Buffer Descriptor (BD) entries. Therefore, a system with 16 fully bidirectional endpoints would require 512 bytes of system memory to implement the BDT. The two BD entries allows for an EVEN BD and ODD BD entry for each endpoint direction. This allows the microprocessor to process one BD while USBFS is processing the other BD. Double buffering BDs in this way allows USBFS to transfer data easily at the maximum throughput provided by USB.

Software should manage buffers for USBFS by updating the BDT when needed. This allows USBFS to efficiently manage data transmission and reception, while the microprocessor performs communication overhead processing and other function dependent applications. Because the buffers are shared between the microprocessor and

USBFS, a simple semaphore mechanism is used to distinguish who is allowed to update the BDT and buffers in system memory. A semaphore, the OWN bit, is cleared to 0 when the BD entry is owned by the microprocessor. The microprocessor is allowed read and write access to the BD entry and the buffer in system memory when the OWN bit is 0. When the OWN bit is set to 1, the BD entry and the buffer in system memory are owned by USBFS. USBFS now has full read and write access and the microprocessor must not modify the BD or its corresponding data buffer. The BD also contains indirect address pointers to where the actual buffer resides in system memory. This indirect address mechanism is shown in the following diagram.

**Figure 48-6. Buffer descriptor table**

### 48.3.2 RX vs. TX as a USB target device or USB host

The USBFS core uses software control to switch between two modes of operation:

- USB target device
- USB hosts

In either mode, USB host or USB target device, the same data paths and buffer descriptors are used for the transmission and reception of data. For this reason, a USBFS core-centric nomenclature is used to describe the direction of the data transfer between the USBFS core and USB:

- "RX" (or "receive") describes transfers that move data from USB to memory.
- "TX" (or "transmit") describes transfers that move data from memory to USB.

The following table shows how the data direction corresponds to the USB token type in host and target device applications.

**Table 48-1. Data direction for USB host or USB target**

|        | RX           | TX           |
|--------|--------------|--------------|
| Device | OUT or SETUP | IN           |
| Host   | IN           | OUT or SETUP |

### 48.3.3 Addressing BDT entries

An understanding of the addressing mechanism of the Buffer Descriptor Table is useful when accessing endpoint data via USBFS or microprocessor. Some points of interest are:

- The BDT occupies up to 512 bytes of system memory.
- 16 bidirectional endpoints can be supported with a full BDT of 512 bytes.
- 16 bytes are needed for each USB endpoint direction.
- Applications with fewer than 16 endpoints require less RAM to implement the BDT.
- The BDT Page Registers (BDT\_PAGE) point to the starting location of the BDT.
- The BDT must be located on a 512-byte boundary in system memory.
- All enabled TX and RX endpoint BD entries are indexed into the BDT to allow easy access via USBFS or MCU core.

When a USB token on an enabled endpoint is received, USBFS uses its integrated DMA controller to interrogate the BDT. USBFS reads the corresponding endpoint BD entry to determine whether it owns the BD and corresponding buffer in system memory.

To compute the entry point in to the BDT, the BDT\_PAGE registers is concatenated with the current endpoint and the TX and ODD fields to form a 32-bit address. This address mechanism is shown in the following tables:

**Table 48-2. BDT Address Calculation**

|             |             |                  |           |    |     |     |
|-------------|-------------|------------------|-----------|----|-----|-----|
| 31:24       | 23:16       | 15:9             | 8:5       | 4  | 3   | 2:0 |
| BDT_PAGE_03 | BDT_PAGE_02 | BDT_PAGE_01[7:1] | End Point | TX | ODD | 000 |

**Table 48-3. BDT address calculation fields**

| Field     | Description  |
|-----------|--|
| BDT_PAGE  | BDT_PAGE registers in the Control Register Block     |
| END_POINT | END POINT field from the USB TOKEN                   |
| TX        | 1 for transmit transfers and 0 for receive transfers |

*Table continues on the next page...*

**Table 48-3. BDT address calculation fields (continued)**

| Field | Description  |
|-------|--|
| ODD   | Maintained within the USBFS SIE. It corresponds to the buffer currently in use. The buffers are used in a ping-pong fashion. |

### 48.3.4 Buffer Descriptors (BDs)

A buffer descriptor provides endpoint buffer control information for USBFS and the processor. The Buffer Descriptors have different meaning based on whether it is USBFS or the processor reading the BD in memory.

The USBFS Controller uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- Whether to release ownership upon packet completion
- No address increment (FIFO mode)
- Whether data toggle synchronization is enabled
- How much data is to be transmitted or received
- Where the buffer resides in system memory

While the processor uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- The received TOKEN PID
- How much data was transmitted or received
- Where the buffer resides in system memory

The format for the BD is shown in the following figure.

**Table 48-4. Buffer descriptor format**

| 31:26 | 25:16           | 15:8 | 7   | 6       | 5                   | 4                   | 3                  | 2                        | 1 | 0 |
|-------|-----------------|------|-----|---------|---------------------|---------------------|--------------------|--------------------------|---|---|
| RSVD  | BC<br>(10 bits) | RSVD | OWN | DATA0/1 | KEEP/<br>TOK_PID[3] | NINC/<br>TOK_PID[2] | DTS/<br>TOK_PID[1] | BDT_STALL/<br>TOK_PID[0] | 0 | 0 |

*Table continues on the next page...*

**Table 48-4. Buffer descriptor format (continued)**

|                          |
|--------------------------|
| Buffer Address (32-Bits) |
|--------------------------|

**Table 48-5. Buffer descriptor fields**

| Field                    | Description   |
|--------------------------|---|
| 31–26<br>RSVD            | Reserved  |
| 25–16<br>BC              | Byte Count<br>Represents the 10-bit byte count. The USBFS SIE changes this field upon the completion of a RX transfer with the byte count of the data received.   |
| 15–8<br>RSVD             | Reserved  |
| 7<br>OWN                 | Determines whether the processor or USBFS currently owns the buffer. Except when KEEP=1, the SIE hands ownership back to the processor after completing the token by clearing this bit.<br><br>This must always be the last byte of the BD that the processor updates when it initializes a BD.<br><br>0 The processor has access to the BD. USBFS ignores all other fields in the BD.<br><br>1 USBFS has access to the BD. While USBFS owns the BD, the processor should not modify any other fields in the BD.  |
| 6<br>DATA0/1             | Defines whether a DATA0 field (DATA0/1=0) or a DATA1 (DATA0/1=1) field was transmitted or received. It is unchanged by USBFS.   |
| 5<br>KEEP/<br>TOK_PID[3] | This bit has two functions: <ul style="list-style-type: none"> <li>• KEEP bit—When written by the processor, it serves as the KEEP bit. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed, the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment.<br/><br/>0 Allows USBFS to release the BD when a token has been processed.<br/><br/>1 This bit is unchanged by USBFS. Bit 3 of the current token PID is written back to the BD by USBFS.</li> <li>• TOK_PID[3]—If the OWN bit is also set, the BD remains owned—by USBFS indefinitely; when written by USB, it serves as the TOK_PID[3] bit.<br/><br/>0 or 1 Bit 3 of the current token PID is written back to the BD by USBFS.</li> </ul> <p>Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed, the data is simply transferred to or from the FIFO. When KEEP is set, normally the NINC bit is also set to prevent address increment.</p> |
| 4<br>NINC/<br>TOK_PID[2] | No Increment (NINC)<br><br>Disables the DMA engine address increment. This forces the DMA engine to read or write from the same address. This is useful for endpoints when data needs to be read from or written to a single location such as a FIFO. Typically this bit is set with the KEEP bit for ISO endpoints that are interfacing to a FIFO.<br><br>0 USBFS writes bit 2 of the current token PID to the BD.<br><br>1 This bit is unchanged by USBFS.  |

*Table continues on the next page...*

**Table 48-5. Buffer descriptor fields (continued)**

| Field                        | Description  |
|------------------------------|--|
| 3<br>DTS/<br>TOK_PID[1]      | <p>Setting this bit enables USBFS to perform Data Toggle Synchronization.</p> <ul style="list-style-type: none"> <li>• If KEEP=0, bit 1 of the current token PID is written back to the BD.</li> <li>• If KEEP=1, this bit is unchanged by USBFS.</li> </ul> <p>0 Data Toggle Synchronization is disabled.<br/>1 Enables USBFS to perform Data Toggle Synchronization.</p>   |
| 2<br>BDT_STALL<br>TOK_PID[0] | <p>Setting this bit causes USBFS to issue a STALL handshake if a token is received by the SIE that would use the BDT in this location. The BDT is not consumed by the SIE (the owns bit remains set and the rest of the BDT is unchanged) when a BDT-STALL bit is set.</p> <ul style="list-style-type: none"> <li>• If KEEP=0, bit 0 of the current token PID is written back to the BD.</li> <li>• If KEEP=1, this bit is unchanged by USBFS.</li> </ul> <p>0 No stall issued.<br/>1 The BDT is not consumed by the SIE (the OWN bit remains set and the rest of the BDT is unchanged).</p> <p>Setting BDT_STALL also causes the corresponding USB_ENDPT<sub>n</sub>[EPSTALL] bit to set. This causes USBOTG to issue a STALL handshake for both directions of the associated endpoint. To clear the stall condition:</p> <ol style="list-style-type: none"> <li>1. Clear the associated USB_ENDPT<sub>n</sub>[EPSTALL] bit.</li> <li>2. Write the BDT to clear OWN and BDT_STALL.</li> </ol> |
| TOK_PID[n]                   | <p>Bits [5:2] can also represent the current token PID. The current token PID is written back in to the BD by USBFS when a transfer completes. The values written back are the token PID values from the USB specification:</p> <ul style="list-style-type: none"> <li>• 0x1h for an OUT token.</li> <li>• 0x9h for an IN token.</li> <li>• 0xDh for a SETUP token.</li> </ul> <p>In host mode, this field is used to report the last returned PID or a transfer status indication. The possible values returned are:</p> <ul style="list-style-type: none"> <li>• 0x3h DATA0</li> <li>• 0xBh DATA1</li> <li>• 0x2h ACK</li> <li>• 0xEh STALL</li> <li>• 0xAh NAK</li> <li>• 0x0h Bus Timeout</li> <li>• 0xFh Data Error</li> </ul>  |
| 1–0<br>Reserved              | Reserved, should read as zeroes.   |
| ADDR[31:0]                   | <p>Address</p> <p>Represents the 32-bit buffer address in system memory. These bits are unchanged by USBFS.</p>  |

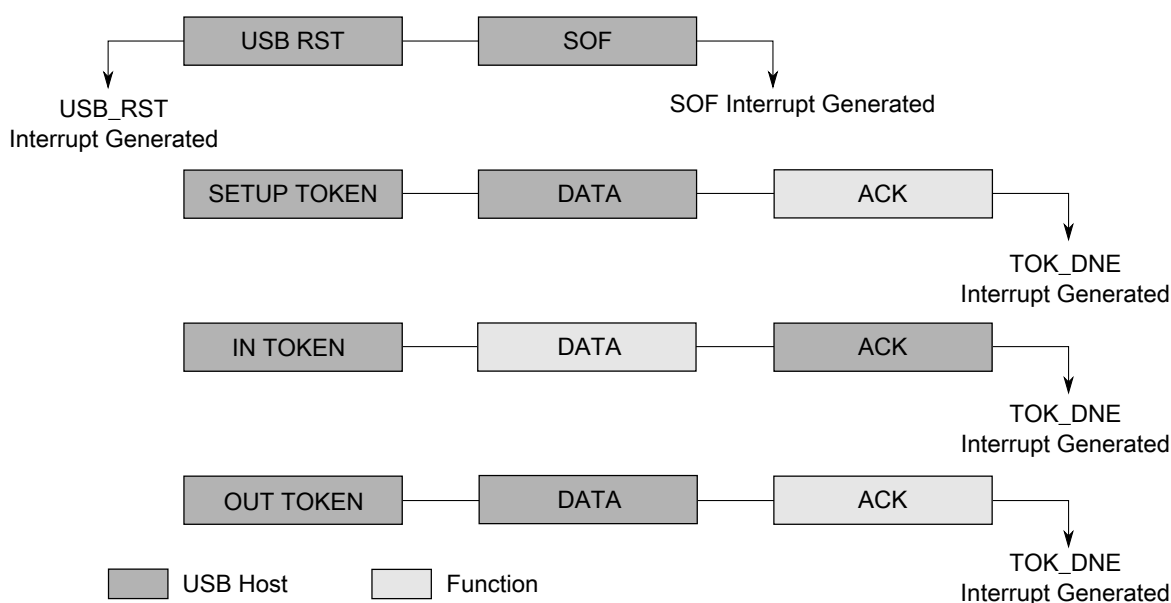

### 48.3.5 USB transaction

When USBFS transmits or receives data, it computes the BDT address using the address generation shown in "Addressing Buffer Descriptor Entries" table.

If OWN =1, the following process occurs:

1. USBFS reads the BDT.
2. The SIE transfers the data via the DMA to or from the buffer pointed to by the ADDR field of the BD.
3. When the TOKEN is complete, USBFS updates the BDT and, if KEEP=0, changes the OWN bit to 0.
4. The STAT register is updated and the TOK\_DNE interrupt is set.
5. When the processor processes the TOK\_DNE interrupt, it reads from the status register all the information needed to process the endpoint.
6. At this point, the processor allocates a new BD so that additional USB data can be transmitted or received for that endpoint, and then processes the last BD.

The following figure shows a timeline of how a typical USB token is processed after the BDT is read and OWN=1.

**Figure 48-7. USB token transaction**

The USB has two sources for the DMA overrun error:

### Memory Latency

The memory latency may be too high and cause the receive FIFO to overflow. This is predominantly a hardware performance issue, usually caused by transient memory access issues.

### Oversized Packets

The packet received may be larger than the negotiated *MaxPacket* size. Typically, this is caused by a software bug. For DMA overrun errors due to oversized data packets, the USB specification is ambiguous. It assumes correct software drivers on both sides. NAKing the packet can result in retransmission of the already oversized packet data. Therefore, in response to oversized packets, the USB core continues ACKing the packet for non-isochronous transfers.

**Table 48-6. USB responses to DMA overrun errors**

| Errors due to Memory Latency   | Errors due to Oversized Packets  |
|--|--|
| Non-Acknowledgment (NAK) or Bus Timeout (BTO) — See bit 4 in "Error Interrupt Status Register (ERRSTAT)" as appropriate for the class of transaction.  | Continues acknowledging (ACKing) the packet for non-isochronous transfers.   |
| —  | The data written to memory is clipped to the MaxPacket size so as not to corrupt system memory.  |
| The DMAERR bit is set in the ERRSTAT register for host and device modes of operation. Depending on the values of the INTENB and ERRENB register, the core may assert an interrupt to notify the processor of the DMA error.  | Asserts ERRSTAT[DMAERR] ,which can trigger an interrupt and TOKDNE interrupt fires. Note: The TOK_PID field of the BDT is not 1111 because the DMAERR is not due to latency. |
| <ul style="list-style-type: none"> <li>For host mode, the TOKDNE interrupt is generated and the TOK_PID field of the BDT is 1111 to indicate the DMA latency error. Host mode software can decide to retry or move to next scheduled item.</li> <li>In device mode, the BDT is not written back nor is the TOKDNE interrupt triggered because it is assumed that a second attempt is queued and will succeed in the future.</li> </ul> | The packet length field written back to the BDT is the MaxPacket value that represents the length of the clipped data actually written to memory.                            |
| From here, the software can decide an appropriate course of action for future transactions such as stalling the endpoint, canceling the transfer, disabling the endpoint, etc.   |  |

## 48.4 Memory map/Register definitions

This section provides the memory map and detailed descriptions of all USB interface registers.

### USB memory map

| Absolute address (hex) | Register name                                      | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|--|-----------------|--------|-------------|-----------------------------|
| 4007_2000              | Peripheral ID register (USB0_PERID)                | 8               | R      | 04h         | <a href="#">48.4.1/1447</a> |
| 4007_2004              | Peripheral ID Complement register (USB0_IDCOMP)    | 8               | R      | FBh         | <a href="#">48.4.2/1448</a> |
| 4007_2008              | Peripheral Revision register (USB0_REV)            | 8               | R      | 33h         | <a href="#">48.4.3/1448</a> |
| 4007_200C              | Peripheral Additional Info register (USB0_ADDINFO) | 8               | R      | 01h         | <a href="#">48.4.4/1449</a> |
| 4007_2010              | OTG Interrupt Status register (USB0_OTGISTAT)      | 8               | R/W    | 00h         | <a href="#">48.4.5/1449</a> |
| 4007_2014              | OTG Interrupt Control register (USB0_OTGICR)       | 8               | R/W    | 00h         | <a href="#">48.4.6/1450</a> |

| 4007_2114              | Frame Adjust Register (USB0_USBFMADJUST)          | 8               | R/W    | 00h         | <a href="#">48.4.28/1469</a> |

#### 48.4.1 Peripheral ID register (USBx\_PERID)

Reads back the value of 0x04. This value is defined for the USB peripheral.

Address: 4007\_2000h base + 0h offset = 4007\_2000h

| Bit   | 7 | 6 | 5  | 4 | 3 | 2 | 1 | 0 |
|-------|---|---|----|---|---|---|---|---|
| Read  | 0 |   | ID |   |   |   |   |   |
| Write |   |   |    |   |   |   |   |   |
| Reset | 0 | 0 | 0  | 0 | 0 | 1 | 0 | 0 |

### USBx\_PERID field descriptions

| Field           | Description   |
|-----------------|---|
| 7–6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 5–0<br>ID       | Peripheral Identification<br>This field always reads 0x4h.                              |

### 48.4.2 Peripheral ID Complement register (USBx\_IDCOMP)

Reads back the complement of the Peripheral ID register. For the USB peripheral, the value is 0xFB.

Address: 4007\_2000h base + 4h offset = 4007\_2004h

### USBx\_IDCOMP field descriptions

| Field           | Description   |
|-----------------|---|
| 7–6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 5–0<br>NID      | Ones' complement of PERID[ID]. bits.  |

### 48.4.3 Peripheral Revision register (USBx\_REV)

Contains the revision number of the USB module.

Address: 4007\_2000h base + 8h offset = 4007\_2008h

### USBx\_REV field descriptions

| Field      | Description  |
|------------|--|
| 7–0<br>REV | Revision<br>Indicates the revision number of the USB Core. |

### 48.4.4 Peripheral Additional Info register (USBx\_ADDINFO)

Reads back the value of the Host Enable bit.

Address: 4007\_2000h base + Ch offset = 4007\_200Ch

|       |   |   |   |   |   |   |        |   |
|-------|---|---|---|---|---|---|--------|---|
| Bit   | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0 |
| Read  | 0 |   |   |   | 0 |   | IEHOST |   |
| Write |   |   |   |   |   |   |        |   |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0      | 1 |

**USBx\_ADDINFO field descriptions**

| Field           | Description   |
|-----------------|---|
| 7-3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 2-1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 0<br>IEHOST     | This bit is set if host mode is enabled.  |

### 48.4.5 OTG Interrupt Status register (USBx\_OTGISTAT)

Records changes of the ID sense and VBUS signals. Software can read this register to determine the event that triggers an interrupt. Only bits that have changed since the last software read are set. Writing a one to a bit clears the associated interrupt.

Address: 4007\_2000h base + 10h offset = 4007\_2010h

|       |       |         |                |   |             |            |   |          |
|-------|-------|---------|----------------|---|-------------|------------|---|----------|
| Bit   | 7     | 6       | 5              | 4 | 3           | 2          | 1 | 0        |
| Read  | IDCHG | ONEMSEC | LINE_STATE_CHG | 0 | SESSVLDC HG | B_SESS_CHG | 0 | AVBUSCHG |
| Write | IDCHG | ONEMSEC | LINE_STATE_CHG |   | SESSVLDC HG | B_SESS_CHG |   | AVBUSCHG |
| Reset | 0     | 0       | 0              | 0 | 0           | 0          | 0 | 0        |

**USBx\_OTGISTAT field descriptions**

| Field        | Description   |
|--------------|---|
| 7<br>IDCHG   | This bit is set when a change in the ID Signal from the USB connector is sensed.  |
| 6<br>ONEMSEC | This bit is set when the 1 millisecond timer expires. This bit stays asserted until cleared by software. The interrupt must be serviced every millisecond to avoid losing 1msec counts. |

*Table continues on the next page...*

### USBx\_OTGISTAT field descriptions (continued)

| Field               | Description   |
|---------------------|---|
| 5<br>LINE_STATE_CHG | This interrupt is set when the USB line state (CTL[SE0] and CTL[JSTATE] bits) are stable without change for 1 millisecond, and the value of the line state is different from the last time when the line state was stable. It is set on transitions between SE0 and J-state, SE0 and K-state, and J-state and K-state. Changes in J-state while SE0 is true do not cause an interrupt. This interrupt can be used in detecting Reset, Resume, Connect, and Data Line Pulse signaling. |
| 4<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3<br>SESSVLDCHG     | This bit is set when a change in VBUS is detected indicating a session valid or a session no longer valid.  |
| 2<br>B_SESS_CHG     | This bit is set when a change in VBUS is detected on a B device.  |
| 1<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 0<br>AVBUSCHG       | This bit is set when a change in VBUS is detected on an A device.   |

### 48.4.6 OTG Interrupt Control register (USBx\_OTGICR)

Enables the corresponding interrupt status bits defined in the OTG Interrupt Status Register.

Address: 4007\_2000h base + 14h offset = 4007\_2014h

| Bit   | 7    | 6             | 5               | 4 | 3             | 2       | 1 | 0       |
|-------|------|---------------|-----------------|---|---------------|---------|---|---------|
| Read  | IDEN | ONEMSEC<br>EN | LINESTATE<br>EN | 0 | SESSVLDE<br>N | BSESSEN | 0 | AVBUSEN |
| Write |      |               |                 |   |               |         |   |         |
| Reset | 0    | 0             | 0               | 0 | 0             | 0       | 0 | 0       |

### USBx\_OTGICR field descriptions

| Field            | Description   |
|------------------|---|
| 7<br>IDEN        | ID Interrupt Enable<br>0 The ID interrupt is disabled<br>1 The ID interrupt is enabled                                  |
| 6<br>ONEMSECEN   | One Millisecond Interrupt Enable<br>0 Disables the 1ms timer interrupt.<br>1 Enables the 1ms timer interrupt.           |
| 5<br>LINESTATEEN | Line State Change Interrupt Enable<br>0 Disables the LINE_STAT_CHG interrupt.<br>1 Enables the LINE_STAT_CHG interrupt. |
| 4<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                 |

Table continues on the next page...

### USBx\_OTGICR field descriptions (continued)

| Field          | Description   |
|----------------|---|
| 3<br>SESSVLDEN | Session Valid Interrupt Enable<br>0 Disables the SESSVLDCHG interrupt.<br>1 Enables the SESSVLDCHG interrupt. |
| 2<br>BSESSEN   | B Session END Interrupt Enable<br>0 Disables the B_SESS_CHG interrupt.<br>1 Enables the B_SESS_CHG interrupt. |
| 1<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                       |
| 0<br>AVBUSEN   | A VBUS Valid Interrupt Enable<br>0 Disables the AVBUSCHG interrupt.<br>1 Enables the AVBUSCHG interrupt.      |

### 48.4.7 OTG Status register (USBx\_OTGSTAT)

Displays the actual value from the external comparator outputs of the ID pin and VBUS.

Address: 4007\_2000h base + 18h offset = 4007\_2018h

|       |          |           |                 |          |
|-------|----------|-----------|-----------------|----------|
| Bit   | 7        | 6         | 5               | 4        |
| Read  | ID       | ONEMSECEN | LINESTATESTABLE | 0        |
| Write |          |           |                 |          |
| Reset | 0        | 0         | 0               | 0        |
| Bit   | 3        | 2         | 1               | 0        |
| Read  | SESS_VLD | BSESSEND  | 0               | AVBUSVLD |
| Write |          |           |                 |          |
| Reset | 0        | 0         | 0               | 0        |

### USBx\_OTGSTAT field descriptions

| Field                | Description   |
|----------------------|---|
| 7<br>ID              | Indicates the current state of the ID pin on the USB connector<br>0 Indicates a Type A cable is plugged into the USB connector.<br>1 Indicates no cable is attached or a Type B cable is plugged into the USB connector.  |
| 6<br>ONEMSECEN       | This bit is reserved for the 1ms count, but it is not useful to software.   |
| 5<br>LINESTATESTABLE | Indicates that the internal signals that control the LINE_STATE_CHG field of OTGSTAT are stable for at least 1 ms. This bit is used to provide a hardware debounce of the linestate in detection of Connect, Disconnect and Resume signaling. First read LINE_STATE_CHG field and then read this field. If this field reads as 1, then the value of LINE_STATE_CHG can be considered stable.<br>0 The LINE_STAT_CHG bit is not yet stable.<br>1 The LINE_STAT_CHG bit has been debounced and is stable. |

Table continues on the next page...

### USBx\_OTGSTAT field descriptions (continued)

| Field         | Description  |
|---------------|--|
| 4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3<br>SESS_VLD | Session Valid<br>0 The VBUS voltage is below the B session valid threshold<br>1 The VBUS voltage is above the B session valid threshold. |
| 2<br>BSESSEND | B Session End<br>0 The VBUS voltage is above the B session end threshold.<br>1 The VBUS voltage is below the B session end threshold.    |
| 1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 0<br>AVBUSVLD | A VBUS Valid<br>0 The VBUS voltage is below the A VBUS Valid threshold.<br>1 The VBUS voltage is above the A VBUS Valid threshold.       |

### 48.4.8 OTG Control register (USBx\_OTGCTL)

Controls the operation of VBUS and Data Line termination resistors.

Address: 4007\_2000h base + 1Ch offset = 4007\_201Ch

### USBx\_OTGCTL field descriptions

| Field         | Description   |
|---------------|---|
| 7<br>DPHIGH   | D+ Data Line pullup resistor enable<br>0 D+ pullup resistor is not enabled<br>1 D+ pullup resistor is enabled   |
| 6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 5<br>DPLOW    | D+ Data Line pull-down resistor enable<br>This bit should always be enabled together with bit 4 (DMLOW)<br>0 D+ pulldown resistor is not enabled.<br>1 D+ pulldown resistor is enabled. |
| 4<br>DMLOW    | D- Data Line pull-down resistor enable<br>0 D- pulldown resistor is not enabled.<br>1 D- pulldown resistor is enabled.  |

Table continues on the next page...

### USBx\_OTGCTL field descriptions (continued)

| Field           | Description  |
|-----------------|--|
| 3<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 2<br>OTGEN      | On-The-Go pullup/pulldown resistor enable<br><br>0 If USB_EN is 1 and HOST_MODE is 0 in the Control Register (CTL), then the D+ Data Line pull-up resistors are enabled. If HOST_MODE is 1 the D+ and D- Data Line pull-down resistors are engaged.<br>1 The pull-up and pull-down controls in this register are used. |
| 1-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

### 48.4.9 Interrupt Status register (USBx\_ISTAT)

Contains fields for each of the interrupt sources within the USB Module. Each of these fields are qualified with their respective interrupt enable bits. All fields of this register are logically OR'd together along with the OTG Interrupt Status Register (OTGSTAT) to form a single interrupt source for the processor's interrupt controller. After an interrupt bit has been set it may only be cleared by writing a one to the respective interrupt bit. This register contains the value of 0x00 after a reset.

Address: 4007\_2000h base + 80h offset = 4007\_2080h

| Bit   | 7     | 6      | 5      | 4     | 3      | 2      | 1     | 0      |
|-------|-------|--------|--------|-------|--------|--------|-------|--------|
| Read  | STALL | ATTACH | RESUME | SLEEP | TOKDNE | SOFTOK | ERROR | USBRST |
| Write | w1c   | w1c    | w1c    | w1c   | w1c    | w1c    | w1c   | w1c    |
| Reset | 0     | 0      | 0      | 0     | 0      | 0      | 0     | 0      |

### USBx\_ISTAT field descriptions

| Field       | Description  |
|-------------|--|
| 7<br>STALL  | Stall Interrupt<br><br>In Target mode this bit is asserted when a STALL handshake is sent by the SIE.<br><br>In Host mode this bit is set when the USB Module detects a STALL acknowledge during the handshake phase of a USB transaction. This interrupt can be used to determine whether the last USB transaction was completed successfully or stalled. |
| 6<br>ATTACH | Attach Interrupt<br><br>This field is set when the USB Module detects an attach of a USB device. This field is only valid if CTL[HOSTMODEEN]=1. This interrupt signifies that a peripheral is now present and must be configured; it is asserted if there have been no transitions on the USB for 2.5 μs and the current bus state is not SE0."            |

*Table continues on the next page...*

### USBx\_ISTAT field descriptions (continued)

| Field       | Description   |
|-------------|---|
|             | 0 No Attach is detected since the last time the ATTACH bit was cleared.<br>1 A peripheral is now present and must be configured (a stable non-SE0 state is detected for more than 2.5 μs).  |
| 5<br>RESUME | This bit is set when a K-state is observed on the DP/DM signals for 2.5 μs. When not in suspend mode this interrupt must be disabled.   |
| 4<br>SLEEP  | This bit is set when the USB Module detects a constant idle on the USB bus for 3 ms. The sleep timer is reset by activity on the USB bus.   |
| 3<br>TOKDNE | This bit is set when the current token being processed has completed. The processor must immediately read the STATUS (STAT) register to determine the EndPoint and BD used for this token. Clearing this bit (by writing a one) causes STAT to be cleared or the STAT holding register to be loaded into the STAT register.                   |
| 2<br>SOFTOK | This bit is set when the USB Module receives a Start Of Frame (SOF) token.<br>In Host mode this field is set when the SOF threshold is reached, so that software can prepare for the next SOF.  |
| 1<br>ERROR  | This bit is set when any of the error conditions within Error Interrupt Status (ERRSTAT) register occur. The processor must then read the ERRSTAT register to determine the source of the error.  |
| 0<br>USBRST | This bit is set when the USB Module has decoded a valid USB reset. This informs the processor that it should write 0x00 into the address register and enable endpoint 0. USBRST is set after a USB reset has been detected for 2.5 microseconds. It is not asserted again until the USB reset condition has been removed and then reasserted. |

#### 48.4.10 Interrupt Enable register (USBx\_INTEN)

Contains enable fields for each of the interrupt sources within the USB Module. Setting any of these bits enables the respective interrupt source in the ISTAT register. This register contains the value of 0x00 after a reset.

Address: 4007\_2000h base + 84h offset = 4007\_2084h

| Bit   | 7       | 6        | 5        | 4       | 3        | 2        | 1       | 0        |
|-------|---------|----------|----------|---------|----------|----------|---------|----------|
| Read  |         |          |          |         |          |          |         |          |
| Write | STALLEN | ATTACHEN | RESUMEEN | SLEEPEN | TOKDNEEN | SOFTOKEN | ERROREN | USBRSTEN |
| Reset | 0       | 0        | 0        | 0       | 0        | 0        | 0       | 0        |

#### USBx\_INTEN field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>STALLEN  | STALL Interrupt Enable<br>0 Disables the STALL interrupt.<br>1 Enables the STALL interrupt.    |
| 6<br>ATTACHEN | ATTACH Interrupt Enable<br>0 Disables the ATTACH interrupt.<br>1 Enables the ATTACH interrupt. |

Table continues on the next page...

**USBx\_INTEN field descriptions (continued)**

| Field         | Description  |
|---------------|--|
| 5<br>RESUMEEN | RESUME Interrupt Enable<br>0 Disables the RESUME interrupt.<br>1 Enables the RESUME interrupt. |
| 4<br>SLEEPEN  | SLEEP Interrupt Enable<br>0 Disables the SLEEP interrupt.<br>1 Enables the SLEEP interrupt.    |
| 3<br>TOKDNEEN | TOKDNE Interrupt Enable<br>0 Disables the TOKDNE interrupt.<br>1 Enables the TOKDNE interrupt. |
| 2<br>SOFTOKEN | SOFTOK Interrupt Enable<br>0 Disables the SOFTOK interrupt.<br>1 Enables the SOFTOK interrupt. |
| 1<br>ERROREN  | ERROR Interrupt Enable<br>0 Disables the ERROR interrupt.<br>1 Enables the ERROR interrupt.    |
| 0<br>USBRSTEN | USBRST Interrupt Enable<br>0 Disables the USBRST interrupt.<br>1 Enables the USBRST interrupt. |

**48.4.11 Error Interrupt Status register (USBx\_ERRSTAT)**

Contains enable bits for each of the error sources within the USB Module. Each of these bits are qualified with their respective error enable bits. All bits of this register are logically OR'd together and the result placed in the ERROR bit of the ISTAT register. After an interrupt bit has been set it may only be cleared by writing a one to the respective interrupt bit. Each bit is set as soon as the error condition is detected. Therefore, the interrupt does not typically correspond with the end of a token being processed. This register contains the value of 0x00 after a reset.

Address: 4007\_2000h base + 88h offset = 4007\_2088h

| Bit   | 7      | 6 | 5      | 4      | 3    | 2     | 1       | 0      |
|-------|--------|---|--------|--------|------|-------|---------|--------|
| Read  | BTSERR | 0 | DMAERR | BTOERR | DFN8 | CRC16 | CRC5EOF | PIDERR |
| Write | w1c    |   | w1c    | w1c    | w1c  | w1c   | w1c     | w1c    |
| Reset | 0      | 0 | 0      | 0      | 0    | 0     | 0       | 0      |

### USBx\_ERRSTAT field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>BTSERR   | This bit is set when a bit stuff error is detected. If set, the corresponding packet is rejected due to the error.   |
| 6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 5<br>DMAERR   | This bit is set if the USB Module has requested a DMA access to read a new BDT but has not been given the bus before it needs to receive or transmit data. If processing a TX transfer this would cause a transmit data underflow condition. If processing a RX transfer this would cause a receive data overflow condition. This interrupt is useful when developing device arbitration hardware for the microprocessor and the USB module to minimize bus request and bus grant latency. This bit is also set if a data packet to or from the host is larger than the buffer size allocated in the BDT. In this case the data packet is truncated as it is put in buffer memory. |
| 4<br>BTOERR   | This bit is set when a bus turnaround timeout error occurs. The USB module contains a bus turnaround timer that keeps track of the amount of time elapsed between the token and data phases of a SETUP or OUT TOKEN or the data and handshake phases of a IN TOKEN. If more than 16 bit times are counted from the previous EOP before a transition from IDLE, a bus turnaround timeout error occurs.  |
| 3<br>DFN8     | This bit is set if the data field received was not 8 bits in length. USB Specification 1.0 requires that data fields be an integral number of bytes. If the data field was not an integral number of bytes, this bit is set.   |
| 2<br>CRC16    | This bit is set when a data packet is rejected due to a CRC16 error.   |
| 1<br>CRC5EOF  | This error interrupt has two functions. When the USB Module is operating in peripheral mode (HOSTMODEEN=0), this interrupt detects CRC5 errors in the token packets generated by the host. If set the token packet was rejected due to a CRC5 error.<br><br>When the USB Module is operating in host mode (HOSTMODEEN=1), this interrupt detects End Of Frame (EOF) error conditions. This occurs when the USB Module is transmitting or receiving data and the SOF counter reaches zero. This interrupt is useful when developing USB packet scheduling software to ensure that no USB transactions cross the start of the next frame.  |
| 0<br>PIDERR   | This bit is set when the PID check field fails.  |

#### 48.4.12 Error Interrupt Enable register (USBx\_ERREN)

Contains enable bits for each of the error interrupt sources within the USB module. Setting any of these bits enables the respective interrupt source in ERRSTAT. Each bit is set as soon as the error condition is detected. Therefore, the interrupt does not typically correspond with the end of a token being processed. This register contains the value of 0x00 after a reset.

Address: 4007\_2000h base + 8Ch offset = 4007\_208Ch

| Bit   | 7        | 6 | 5        | 4        | 3      | 2       | 1             | 0        |
|-------|----------|---|----------|----------|--------|---------|---------------|----------|
| Read  | BTSERREN | 0 | DMAERREN | BTOERREN | DFN8EN | CRC16EN | CRC5EOFE<br>N | PIDERREN |
| Write |          |   |          |          |        |         |               |          |
| Reset | 0        | 0 | 0        | 0        | 0      | 0       | 0             | 0        |

### USBx\_ERREN field descriptions

| Field          | Description  |
|----------------|--|
| 7<br>BTSERREN  | BTSERR Interrupt Enable<br>0 Disables the BTSERR interrupt.<br>1 Enables the BTSERR interrupt.       |
| 6<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.              |
| 5<br>DMAERREN  | DMAERR Interrupt Enable<br>0 Disables the DMAERR interrupt.<br>1 Enables the DMAERR interrupt.       |
| 4<br>BTOERREN  | BTOERR Interrupt Enable<br>0 Disables the BTOERR interrupt.<br>1 Enables the BTOERR interrupt.       |
| 3<br>DFN8EN    | DFN8 Interrupt Enable<br>0 Disables the DFN8 interrupt.<br>1 Enables the DFN8 interrupt.             |
| 2<br>CRC16EN   | CRC16 Interrupt Enable<br>0 Disables the CRC16 interrupt.<br>1 Enables the CRC16 interrupt.          |
| 1<br>CRC5EOFEN | CRC5/EOF Interrupt Enable<br>0 Disables the CRC5/EOF interrupt.<br>1 Enables the CRC5/EOF interrupt. |
| 0<br>PIDERREN  | PIDERR Interrupt Enable<br>0 Disables the PIDERR interrupt.<br>1 Enters the PIDERR interrupt.        |

### 48.4.13 Status register (USBx\_STAT)

Reports the transaction status within the USB module. When the processor's interrupt controller has received a TOKDNE, interrupt the Status Register must be read to determine the status of the previous endpoint communication. The data in the status register is valid when TOKDNE interrupt is asserted. The Status register is actually a read window into a status FIFO maintained by the USB module. When the USB module uses a BD, it updates the Status register. If another USB transaction is performed before the TOKDNE interrupt is serviced, the USB module stores the status of the next transaction in the STAT FIFO. Thus STAT is actually a four byte FIFO that allows the processor core to process one transaction while the SIE is processing the next transaction. Clearing the TOKDNE bit in the ISTAT register causes the SIE to update STAT with the contents of the next STAT value. If the data in the STAT holding register is valid, the SIE immediately reasserts to TOKDNE interrupt.

Address: 4007\_2000h base + 90h offset = 4007\_2090h

#### USBx\_STAT field descriptions

| Field           | Description   |
|-----------------|---|
| 7-4<br>ENDP     | This four-bit field encodes the endpoint address that received or transmitted the previous token. This allows the processor core to determine the BDT entry that was updated by the last USB transaction. |
| 3<br>TX         | Transmit Indicator<br>0 The most recent transaction was a receive operation.<br>1 The most recent transaction was a transmit operation.   |
| 2<br>ODD        | This bit is set if the last buffer descriptor updated was in the odd bank of the BDT.   |
| 1-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 48.4.14 Control register (USBx\_CTL)

Provides various control and configuration information for the USB module.

Address: 4007\_2000h base + 94h offset = 4007\_2094h

|       |            |        |                    |            |
|-------|------------|--------|--------------------|------------|
| Bit   | 7          | 6      | 5                  | 4          |
| Read  | JSTATE     | SE0    | TXSUSPENDTOKENBUSY | RESET      |
| Write |            |        |                    |            |
| Reset | 0          | 0      | 0                  | 0          |
| Bit   | 3          | 2      | 1                  | 0          |
| Read  | HOSTMODEEN | RESUME | ODDRST             | USBENSOFEN |
| Write |            |        |                    |            |
| Reset | 0          | 0      | 0                  | 0          |

#### USBx\_CTL field descriptions

| Field                   | Description   |
|-------------------------|---|
| 7<br>JSTATE             | Live USB differential receiver JSTATE signal<br>The polarity of this signal is affected by the current state of LSEN .  |
| 6<br>SE0                | Live USB Single Ended Zero signal   |
| 5<br>TXSUSPENDTOKENBUSY | In Host mode, TOKEN_BUSY is set when the USB module is busy executing a USB token. Software must not write more token commands to the Token Register when TOKEN_BUSY is set. Software should check this field before writing any tokens to the Token Register to ensure that token commands are not lost.<br><br>In Target mode, TXD_SUSPEND is set when the SIE has disabled packet transmission and reception. Clearing this bit allows the SIE to continue token processing. This bit is set by the SIE when a SETUP Token is received allowing software to dequeue any pending packet transactions in the BDT before resuming token processing. |
| 4<br>RESET              | Setting this bit enables the USB Module to generate USB reset signaling. This allows the USB Module to reset USB peripherals. This control signal is only valid in Host mode (HOSTMODEEN=1). Software must set RESET to 1 for the required amount of time and then clear it to 0 to end reset signaling. For more information on reset signaling see Section 7.1.4.3 of the USB specification version 1.0.  |
| 3<br>HOSTMODEEN         | When set to 1, this bit enables the USB Module to operate in Host mode. In host mode, the USB module performs USB transactions under the programmed control of the host processor.  |
| 2<br>RESUME             | When set to 1 this bit enables the USB Module to execute resume signaling. This allows the USB Module to perform remote wake-up. Software must set RESUME to 1 for the required amount of time and then clear it to 0. If the HOSTMODEEN bit is set, the USB module appends a Low Speed End of Packet to the Resume signaling when the RESUME bit is cleared. For more information on RESUME signaling see Section 7.1.4.5 of the USB specification version 1.0.  |
| 1<br>ODDRST             | Setting this bit to 1 resets all the BDT ODD ping/pong fields to 0, which then specifies the EVEN BDT bank.   |
| 0<br>USBENSOFEN         | USB Enable<br><br>Setting this bit enables the USB-FS to operate; clearing it disables the USB-FS. Setting the bit causes the SIE to reset all of its ODD bits to the BDTs. Therefore, setting this bit resets much of the logic in the SIE.  |

Table continues on the next page...

### USBx\_CTL field descriptions (continued)

| Field | Description   |
|-------|---|
|       | When host mode is enabled, clearing this bit causes the SIE to stop sending SOF tokens. |
|       | 0 Disables the USB Module.  |
|       | 1 Enables the USB Module.   |

### 48.4.15 Address register (USBx\_ADDR)

Holds the unique USB address that the USB module decodes when in Peripheral mode (HOSTMODEEN=0). When operating in Host mode (HOSTMODEEN=1) the USB module transmits this address with a TOKEN packet. This enables the USB module to uniquely address any USB peripheral. In either mode, CTL[USBENSOFEN] must be 1. The Address register is reset to 0x00 after the reset input becomes active or the USB module decodes a USB reset signal. This action initializes the Address register to decode address 0x00 as required by the USB specification.

Address: 4007\_2000h base + 98h offset = 4007\_2098h

|       |      |   |   |   |      |   |   |   |
|-------|------|---|---|---|------|---|---|---|
| Bit   | 7    | 6 | 5 | 4 | 3    | 2 | 1 | 0 |
| Read  | LSEN |   |   |   | ADDR |   |   |   |
| Write | LSEN |   |   |   | ADDR |   |   |   |
| Reset | 0    | 0 | 0 | 0 | 0    | 0 | 0 | 0 |

### USBx\_ADDR field descriptions

| Field       | Description   |
|-------------|---|
| 7<br>LSEN   | Low Speed Enable bit<br><br>Informs the USB module that the next token command written to the token register must be performed at low speed. This enables the USB module to perform the necessary preamble required for low-speed data transmissions. |
| 6-0<br>ADDR | USB Address<br><br>Defines the USB address that the USB module decodes in peripheral mode, or transmits when in host mode.  |

### 48.4.16 BDT Page register 1 (USBx\_BDTPAGE1)

Provides address bits 15 through 9 of the base address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#). The 32-bit BDT Base Address is always aligned on 512-byte boundaries, so bits 8 through 0 of the base address are always zero.

Address: 4007\_2000h base + 9Ch offset = 4007\_209Ch

#### USBx\_BDTPAGE1 field descriptions

| Field         | Description   |
|---------------|---|
| 7-1<br>BDTBA  | Provides address bits 15 through 9 of the BDT base address.                             |
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 48.4.17 Frame Number register Low (USBx\_FRMNUML)

The Frame Number registers (low and high) contain the 11-bit frame number. These registers are updated with the current frame number whenever a SOF TOKEN is received.

Address: 4007\_2000h base + A0h offset = 4007\_20A0h

#### USBx\_FRMNUML field descriptions

| Field           | Description  |
|-----------------|--|
| 7-0<br>FRM[7:0] | This 8-bit field and the 3-bit field in the Frame Number Register High are used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. |

## 48.4.18 Frame Number register High (USBx\_FRMNUMH)

The Frame Number registers (low and high) contain the 11-bit frame number. These registers are updated with the current frame number whenever a SOF TOKEN is received.

Address: 4007\_2000h base + A4h offset = 4007\_20A4h

|       |   |   |   |           |   |   |   |   |
|-------|---|---|---|-----------|---|---|---|---|
| Bit   | 7 | 6 | 5 | 4         | 3 | 2 | 1 | 0 |
| Read  | 0 |   |   | FRM[10:8] |   |   |   |   |
| Write |   |   |   |           |   |   |   |   |
| Reset | 0 | 0 | 0 | 0         | 0 | 0 | 0 | 0 |

### USBx\_FRMNUMH field descriptions

| Field            | Description   |
|------------------|---|
| 7-3<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2-0<br>FRM[10:8] | This 3-bit field and the 8-bit field in the Frame Number Register Low are used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. |

## 48.4.19 Token register (USBx\_TOKEN)

Used to initiate USB transactions when in host mode (HOSTMODEEN=1). When the software needs to execute a USB transaction to a peripheral, it writes the TOKEN type and endpoint to this register. After this register has been written, the USB module begins the specified USB transaction to the address contained in the address register. The processor core must always check that the TOKEN\_BUSY bit in the control register is not 1 before writing to the Token Register. This ensures that the token commands are not overwritten before they can be executed. The address register and endpoint control register 0 are also used when performing a token command and therefore must also be written before the Token Register. The address register is used to select the USB peripheral address transmitted by the token command. The endpoint control register determines the handshake and retry policies used during the transfer.

Address: 4007\_2000h base + A8h offset = 4007\_20A8h

|       |          |   |   |   |            |   |   |   |
|-------|----------|---|---|---|------------|---|---|---|
| Bit   | 7        | 6 | 5 | 4 | 3          | 2 | 1 | 0 |
| Read  | TOKENPID |   |   |   | TOKENENDPT |   |   |   |
| Write |          |   |   |   |            |   |   |   |
| Reset | 0        | 0 | 0 | 0 | 0          | 0 | 0 | 0 |

### USBx\_TOKEN field descriptions

| Field             | Description   |
|-------------------|---|
| 7-4<br>TOKENPID   | Contains the token type executed by the USB module.<br><br>0001 OUT Token. USB Module performs an OUT (TX) transaction.<br>1001 IN Token. USB Module performs an In (RX) transaction.<br>1101 SETUP Token. USB Module performs a SETUP (TX) transaction |
| 3-0<br>TOKENENDPT | Holds the Endpoint address for the token command. The four bit value written must be a valid endpoint.  |

#### 48.4.20 SOF Threshold register (USBx\_SOFTHLD)

The SOF Threshold Register is used only in Host mode (HOSTMODEEN=1). When in Host mode, the 14-bit SOF counter counts the interval between SOF frames. The SOF must be transmitted every 1ms so therefore the SOF counter is loaded with a value of 12000. When the SOF counter reaches zero, a Start Of Frame (SOF) token is transmitted.

The SOF threshold register is used to program the number of USB byte times before the SOF to stop initiating token packet transactions. This register must be set to a value that ensures that other packets are not actively being transmitted when the SOF time counts to zero. When the SOF counter reaches the threshold value, no more tokens are transmitted until after the SOF has been transmitted.

The value programmed into the threshold register must reserve enough time to ensure the worst case transaction completes. In general the worst case transaction is an IN token followed by a data packet from the target followed by the response from the host. The actual time required is a function of the maximum packet size on the bus.

Typical values for the SOF threshold are:

- 64-byte packets=74;
- 32-byte packets=42;
- 16-byte packets=26;
- 8-byte packets=18.

Address: 4007\_2000h base + ACh offset = 4007\_20ACh

### USBx\_SOFTHLD field descriptions

| Field      | Description                                       |
|------------|---|
| 7-0<br>CNT | Represents the SOF count threshold in byte times. |

### 48.4.21 BDT Page Register 2 (USBx\_BDTPAGE2)

Contains an 8-bit value used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#).

Address: 4007\_2000h base + B0h offset = 4007\_20B0h

#### USBx\_BDTPAGE2 field descriptions

| Field        | Description  |
|--------------|--|
| 7-0<br>BDTBA | Provides address bits 23 through 16 of the BDT base address that defines the location of Buffer Descriptor Table resides in system memory. |

### 48.4.22 BDT Page Register 3 (USBx\_BDTPAGE3)

Contains an 8-bit value used to compute the address where the current Buffer Descriptor Table (BDT) resides in system memory. See [Buffer Descriptor Table](#).

Address: 4007\_2000h base + B4h offset = 4007\_20B4h

#### USBx\_BDTPAGE3 field descriptions

| Field        | Description  |
|--------------|--|
| 7-0<br>BDTBA | Provides address bits 31 through 24 of the BDT base address that defines the location of Buffer Descriptor Table resides in system memory. |

### 48.4.23 Endpoint Control register (USBx\_ENDPTn)

Contains the endpoint control bits for each of the 16 endpoints available within the USB module for a decoded address. The format for these registers is shown in the following figure. Endpoint 0 (ENDPT0) is associated with control pipe 0, which is required for all USB functions. Therefore, after a USBRST interrupt occurs the processor core should set ENDPT0 to contain 0x0D.

In Host mode ENDPT0 is used to determine the handshake, retry and low speed characteristics of the host transfer. For Control, Bulk and Interrupt transfers, the EPHSHK bit should be 1. For Isochronous transfers it should be 0. Common values to use for ENDPT0 in host mode are 0x4D for Control, Bulk, and Interrupt transfers, and 0x4C for Isochronous transfers.

The three bits EPCTLDIS, EPRXEN, and EPTXEN define if an endpoint is enabled and define the direction of the endpoint. The endpoint enable/direction control is defined in the following table.

**Table 48-93. Endpoint enable and direction control**

| EPCTLDIS | EPRXEN | EPTXEN | Endpoint enable/direction control                                   |
|----------|--------|--------|---|
| X        | 0      | 0      | Disable endpoint  |
| X        | 0      | 1      | Enable endpoint for Tx transfers only                               |
| X        | 1      | 0      | Enable endpoint for Rx transfers only                               |
| 1        | 1      | 1      | Enable endpoint for Rx and Tx transfers                             |
| 0        | 1      | 1      | Enable Endpoint for RX and TX as well as control (SETUP) transfers. |

Address: 4007\_2000h base + C0h offset + (4d × i), where i=0d to 15d

| Bit   | 7       | 6        | 5 | 4        | 3      | 2      | 1       | 0      |
|-------|---------|----------|---|----------|--------|--------|---------|--------|
| Read  | HOSTWOH | RETRYDIS | 0 | EPCTLDIS | EPRXEN | EPTXEN | EPSTALL | EPHSHK |
| Write | UB      |          |   |          |        |        |         |        |
| Reset | 0       | 0        | 0 | 0        | 0      | 0      | 0       | 0      |

#### USBx\_ENDPTn field descriptions

| Field          | Description  |
|----------------|--|
| 7<br>HOSTWOHUB | Host without a hub This is a Host mode only field and is present in the control register for endpoint 0 (ENDPT0) only. |

Table continues on the next page...

### USBx\_ENDPTn field descriptions (continued)

| Field         | Description  |
|---------------|--|
|               | 0 Low-speed device connected to Host through a hub. PRE_PID will be generated as required.<br>1 Low-speed device directly connected. No hub, or no low-speed device attached.  |
| 6<br>RETRYDIS | This is a Host mode only bit and is present in the control register for endpoint 0 (ENDPT0) only. When set this bit causes the host to not retry NAK'ed (Negative Acknowledgement) transactions. When a transaction is NAKed, the BDT PID field is updated with the NAK PID, and the TOKEN_DNE interrupt is set. When this bit is cleared, NAKed transactions are retried in hardware. This bit must be set when the host is attempting to poll an interrupt endpoint. |
| 5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4<br>EPCTLDIS | This bit, when set, disables control (SETUP) transfers. When cleared, control transfers are enabled. This applies if and only if the EPRXEN and EPTXEN bits are also set. See <a href="#">Table 48-31</a>  |
| 3<br>EPRXEN   | This bit, when set, enables the endpoint for RX transfers. See <a href="#">Table 48-31</a>   |
| 2<br>EPTXEN   | This bit, when set, enables the endpoint for TX transfers. See <a href="#">Table 48-31</a>   |
| 1<br>EPSTALL  | When set this bit indicates that the endpoint is stalled. This bit has priority over all other control bits in the EndPoint Enable Register, but it is only valid if EPTXEN=1 or EPRXEN=1. Any access to this endpoint causes the USB Module to return a STALL handshake. After an endpoint is stalled it requires intervention from the Host Controller.  |
| 0<br>EPHSBK   | When set this bit enables an endpoint to perform handshaking during a transaction to this endpoint. This bit is generally 1 unless the endpoint is Isochronous.  |

### 48.4.24 USB Control register (USBx\_USBCTRL)

Address: 4007\_2000h base + 100h offset = 4007\_2100h

|       |      |     |   |   |   |   |   |   |
|-------|------|-----|---|---|---|---|---|---|
| Bit   | 7    | 6   | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | SUSP | PDE | 0 |   |   |   |   |   |
| Write | 0    |     |   |   |   |   |   |   |
| Reset | 1    | 1   | 0 | 0 | 0 | 0 | 0 | 0 |

### USBx\_USBCTRL field descriptions

| Field           | Description   |
|-----------------|---|
| 7<br>SUSP       | Places the USB transceiver into the suspend state.<br>0 USB transceiver is not in suspend state.<br>1 USB transceiver is in suspend state.      |
| 6<br>PDE        | Enables the weak pulldowns on the USB transceiver.<br>0 Weak pulldowns are disabled on D+ and D-.<br>1 Weak pulldowns are enabled on D+ and D-. |
| 5-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 48.4.25 USB OTG Observe register (USBx\_OBSERVE)

Provides visibility on the state of the pull-ups and pull-downs at the transceiver. Useful when interfacing to an external OTG control module via a serial interface.

Address: 4007\_2000h base + 104h offset = 4007\_2104h

|       |      |      |   |      |   |   |   |   |
|-------|------|------|---|------|---|---|---|---|
| Bit   | 7    | 6    | 5 | 4    | 3 | 2 | 1 | 0 |
| Read  | DPPU | DPPD | 0 | DMPD | 0 |   | 0 |   |
| Write |      |      |   |      |   |   |   |   |
| Reset | 0    | 1    | 0 | 1    | 0 | 0 | 0 | 0 |

#### USBx\_OBSERVE field descriptions

| Field           | Description   |
|-----------------|---|
| 7<br>DPPU       | Provides observability of the D+ Pullup enable at the USB transceiver.<br>0 D+ pullup disabled.<br>1 D+ pullup enabled.       |
| 6<br>DPPD       | Provides observability of the D+ Pulldown enable at the USB transceiver.<br>0 D+ pulldown disabled.<br>1 D+ pulldown enabled. |
| 5<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                       |
| 4<br>DMPD       | Provides observability of the D- Pulldown enable at the USB transceiver.<br>0 D- pulldown disabled.<br>1 D- pulldown enabled. |
| 3-1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                       |
| 0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                       |

### 48.4.26 USB OTG Control register (USBx\_CONTROL)

Address: 4007\_2000h base + 108h offset = 4007\_2108h

|                |   |   |   |   |
|----------------|---|---|---|---|
| Bit            | 7 | 6 | 5 | 4 |
| Read           | 0 |   |   |   |
| Write          |   |   |   |   |
| Reset          | 0 | 0 | 0 | 0 |
| DPPULLUPNONOTG |   |   |   |   |
| Bit            | 3 | 2 | 1 | 0 |
| Read           | 0 |   |   |   |
| Write          |   |   |   |   |
| Reset          | 0 | 0 | 0 | 0 |

### USBx\_CONTROL field descriptions

| Field               | Description   |
|---------------------|---|
| 7–5<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 4<br>DPPULLUPNONOTG | Provides control of the DP Pullup in USBOTG, if USB is configured in non-OTG device mode.<br>0 DP Pullup in non-OTG device mode is not enabled.<br>1 DP Pullup in non-OTG device mode is enabled. |
| 3–0<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 48.4.27 USB Transceiver Control register 0 (USBx\_USBTRC0)

Includes signals for basic operation of the on-chip USB Full Speed transceiver and configuration of the USB data connection that are not otherwise included in the USB Full Speed controller registers.

Address: 4007\_2000h base + 10Ch offset = 4007\_210Ch

|       |          |   |           |                |
|-------|----------|---|-----------|----------------|
| Bit   | 7        | 6 | 5         | 4              |
| Read  |          |   | 0         | 0              |
| Write | USBRESET |   | USBRESMEN |                |
| Reset | 0        | 0 | 0         | 0              |
| Bit   | 3        | 2 | 1         | 0              |
| Read  | 0        |   | SYNC_DET  | USB_RESUME_INT |
| Write |          |   |           |                |
| Reset | 0        | 0 | 0         | 0              |

### USBx\_USBTRC0 field descriptions

| Field          | Description  |
|----------------|--|
| 7<br>USBRESET  | USB Reset<br>Generates a hard reset to USBOTG. After this bit is set and the reset occurs, this bit is automatically cleared.<br><br><b>NOTE: This bit is always read as zero. ### USBx\_USBTRC0 field descriptions (continued)

| Field               | Description   |
|---------------------|---|
|                     | used for low-power suspend mode when USB module clocks are stopped or the USB transceiver is in Suspend mode. Async wakeup only works in device mode.<br><br>0 USB asynchronous wakeup from suspend mode disabled.<br>1 USB asynchronous wakeup from suspend mode enabled. The asynchronous resume interrupt differs from the synchronous resume interrupt in that it asynchronously detects K-state using the unfiltered state of the D+ and D- pins. This interrupt should only be enabled when the Transceiver is suspended. |
| 4–2<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 1<br>SYNC_DET       | Synchronous USB Interrupt Detect<br><br>0 Synchronous interrupt has not been detected.<br>1 Synchronous interrupt has been detected.  |
| 0<br>USB_RESUME_INT | USB Asynchronous Interrupt<br><br>0 No interrupt was generated.<br>1 Interrupt was generated because of the USB asynchronous interrupt.   |

### 48.4.28 Frame Adjust Register (USBx\_USBFRMADJUST)

Address: 4007\_2000h base + 114h offset = 4007\_2114h

### USBx\_USBFRMADJUST field descriptions

| Field      | Description   |
|------------|---|
| 7–0<br>ADJ | Frame Adjustment<br><br>In Host mode, the frame adjustment is a twos complement number that adjusts the period of each USB frame in 12-MHz clock periods. A SOF is normally generated every 12,000 12-MHz clock cycles. The Frame Adjust Register can adjust this by -128 to +127 to compensate for inaccuracies in the USB 48-MHz clock. Changes to the ADJ bit take effect at the next start of the next frame. |

## 48.5 OTG and Host mode operation

The Host mode logic allows devices such as digital cameras and palmtop computers to function as a USB Host Controller. The OTG logic adds an interface to allow the OTG Host Negotiation and Session Request Protocols (HNP and SRP) to be implemented in software. Host Mode allows a peripheral such as a digital camera to be connected directly to a USB compliant printer. Digital photos can then be easily printed without being

uploaded to a PC. In the palmtop computer application, a USB compliant keyboard/mouse can be connected to the palmtop computer with the obvious advantages of easier interaction.

Host mode is intended for use in handheld-portable devices to allow easy connection to simple HID class devices such as printers and keyboards. It is not intended to perform the functions of a full OHCI or UHCI compatible host controller found on PC motherboards. The USB-FS is not supported by Windows as a USB host controller. Host mode allows bulk, isochronous, interrupt and control transfers. Bulk data transfers are performed at nearly the full USB interface bandwidth. Support is provided for ISO transfers, but the number of ISO streams that can be practically supported is affected by the interrupt latency of the processor servicing the Token Done interrupts from the SIE. Custom drivers must be written to support Host mode operation.

Setting the HOST\_MODE\_EN bit in the CTL register enables Host mode. The USB-FS core can only operate as a peripheral device or in Host mode. It cannot operate in both modes simultaneously. When HOST\_MODE is enabled, only endpoint zero is used. All other endpoints should be disabled by software.

## 48.6 Host Mode Operation Examples

The following sections illustrate the steps required to perform USB host functions using the USB-FS core. While it is useful to understand the interaction of the hardware and the software at a detailed level, an understanding of the interactions at this level is not required to write host applications using the API software.

To enable host mode and discover a connected device:

1. Enable Host Mode (CTL[HOST\_MODE\_EN]=1). The pull-down resistors are enabled, and pull-up disabled. Start of Frame (SOF) generation begins. SOF counter loaded with 12,000. Disable SOF packet generation to eliminate noise on the USB by writing the USB enable bit to 0 (CTL[USB\_EN]=0).
2. Enable the ATTACH interrupt (INT\_ENB[ATTACH]=1).
3. Wait for ATTACH interrupt (INT\_STAT[ATTACH]). Signaled by USB Target pull-up resistor changing the state of DPLUS or DMINUS from 0 to 1 (SE0 to J or K state).
4. Check the state of the JSTATE and SE0 bits in the control register. If the connecting device is low speed (JSTATE bit is 0), set the low-speed bit in the address registers (ADDR[LS\_EN]=1) and the Host Without Hub bit in endpoint 0 register control (ENDPT0[HOSTWOHUB]=1).

5. Enable RESET (CTL[RESET]=1) for 10 ms.
6. Enable SOF packet to keep the connected device from going to suspend (CTL[USB\_EN=1]).
7. Enumerate the attached device by sending the appropriate commands to the default control pipe of the connected device. See the *Universal Serial Bus Revision 2.0 specification*, "Chapter 9 USB Device Framework" (<http://www.usb.org/developers/docs>).

To complete a control transaction to a connected device:

1. Complete all the steps to discover a connected device
2. Set up the endpoint control register for bidirectional control transfers ENDPT0[4:0] = 0x0d.
3. Place a copy of the device framework setup command in a memory buffer. See the *Universal Serial Bus Revision 2.0 specification*, "Chapter 9 USB Device Framework" (<http://www.usb.org/developers/docs>).
4. Initialize current even or odd TX EP0 BDT to transfer the 8 bytes of command data for a device framework command (for example, a GET DEVICE DESCRIPTOR).
  - Set the BDT command word to 0x00080080 –Byte count to 8, OWN bit to 1.
  - Set the BDT buffer address field to the start address of the 8 byte command buffer.
5. Set the USB device address of the target device in the address register (ADDR[6:0]). After the USB bus reset, the device USB address is zero. It is set to some other value usually 1 by the Set Address device framework command.
6. Write the TOKEN register with a SETUP to Endpoint 0, the target device default control pipe (TOKEN=0xD0). This initiates a setup token on the bus followed by a data packet. The device handshake is returned in the BDT PID field after the packets complete. When the BDT is written, a Token Done (ISTAT[TOKDNE]) interrupt is asserted. This completes the setup phase of the setup transaction. See the *Universal Serial Bus Revision 2.0 specification*, "Chapter 9 USB Device Framework" (<http://www.usb.org/developers/docs>).
7. To initiate the data phase of the setup transaction (that is, get the data for the GET DEVICE DESCRIPTOR command), set up a buffer in memory for the data to be transferred.
8. Initialize the current even or odd TX EP0 BDT to transfer the data.

- Set the BDT command word to 0x004000C0 – BC to 64 (the byte count of the data buffer in this case), OWN bit to 1, Data toggle to Data1.
  - Set the BDT buffer address field to the start address of the data buffer
9. Write the TOKEN register with an IN or OUT token to Endpoint 0, the target device default control pipe, an IN token for a GET DEVICE DESCRIPTOR command (TOKEN=0x90). This initiates an IN token on the bus followed by a data packet from the device to the host. When the data packet completes, the BDT is written and a Token Done (ISTAT[DNE]) interrupt is asserted. For control transfers with a single packet data phase this completes the data phase of the setup transaction. See the *Universal Serial Bus Revision 2.0 specification*, "Chapter 9 USB Device Framework" (<http://www.usb.org/developers/docs>).
  10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
  11. Initialize the current even or odd TX EP0 BDT to transfer the status data.
    - Set the BDT command word to 0x00000080 – BC to 0 (the byte count of the data buffer in this case), OWN bit to 1, Data toggle to Data1.
    - Set the BDT buffer address field to the start address of the data buffer
  12. Write the TOKEN register with a IN or OUT token to Endpoint 0, the target device default control pipe, an OUT token for a GET DEVICE DESCRIPTOR command (TOKEN=0x10). This initiates an OUT token on the bus followed by a zero length data packet from the host to the device. When the data packet completes, the BDT is written with the handshake from the device and a Token Done (ISTAT[TOKDNE]) interrupt is asserted. This completes the data phase of the setup transaction. See the *Universal Serial Bus Revision 2.0 specification*, "Chapter 9 USB Device Framework" (<http://www.usb.org/developers/docs>).

To send a full speed bulk data transfer to a target device:

1. Complete all steps to discover a connected device and to configure a connected device. Write the ADDR register with the address of the target device. Typically, there is only one other device on the USB bus in host mode so it is expected that the address is 0x01 and should remain constant.
2. Write 0x1D to ENDPT0 register to enable transmit and receive transfers with handshaking enabled.
3. Setup the even TX EP0 BDT to transfer up to 64 bytes.
4. Set the USB device address of the target device in the address register (ADDR[6:0]).

5. Write the TOKEN register with an OUT token to the desired endpoint. The write to this register triggers the USB-FS transmit state machines to begin transmitting the token and the data.
6. Setup the odd TX EP0 BDT to transfer up to 64 bytes.
7. Write the TOKEN register with an OUT token as in step 4. Two tokens can be queued at a time to allow the packets to be double buffered to achieve maximum throughput.
8. Wait for the TOKDNE interrupt. This indicates that one of the BDTs has been released back to the processor and the transfer has completed. If the target device asserts NAKs, the USB-FS continues to retry the transfer indefinitely without processor intervention unless the ENDPT0[RETRYDIS] is 1. If the retry disable field is set, the handshake (ACK, NAK, STALL, or ERROR (0xf)) is returned in the BDT PID field. If a stall interrupt occurs, the pending packet must be dequeued and the error condition in the target device cleared. If a Reset interrupt occurs (SE0 for more than 2.5  $\mu$ s), the target has detached.
9. After the TOK\_DNE interrupt occurs, the BDTs can be examined and the next data packet queued by returning to step 2.

## 48.7 On-The-Go operation

The USB-OTG core provides sensors and controls to enable On-The-Go (OTG) operation. These sensors are used by the OTG API software to implement the Host Negotiation Protocol (HNP) and Session Request Protocol (SRP). API calls are provided to give access to the OTG protocol control signals, and include the OTG capabilities in the device application. The following state machines show the OTG operations involved with HNP and SRP protocols from either end of the USB cable.

### 48.7.1 OTG dual role A device operation

A device is considered the A device because of the type of cable attached. If the USB Type A connector or the USB Type Mini A connector is plugged into the device, it is considered the A device.

A dual role A device operates as the following flow diagram and state description table illustrates.

**Figure 48-96. Dual role A device flow diagram**

**Table 48-131. State descriptions for the dual role A device flow**

| State        | Action   | Response  |
|--------------|--|---|
| A_IDLE       | If ID Interrupt.<br>The cable has been unplugged or a Type B cable has been attached. The device now acts as a Type B device.  | Go to B_IDLE  |
|              | If the A application wants to use the bus or if the B device is doing an SRP as indicated by an A_SESS_VLD Interrupt or Attach or Port Status Change Interrupt check data line for 5 –10 msec pulsing. | Go to A_WAIT_VRISE<br>Turn on DRV_VBUS                        |
| A_WAIT_VRISE | If ID Interrupt or if A_VBUS_VLD is false after 100 msec<br>The cable has been changed or the A device cannot support the current required from the B device.  | Go to A_WAIT_VFALL<br>Turn off DRV_VBUS                       |
|              | If A_VBUS_VLD interrupt  | Go to A_WAIT_BCON   |
| A_WAIT_BCON  | After 200 ms without Attach or ID Interrupt. (This could wait forever if desired.)   | Go to A_WAIT_FALL<br>Turn off DRV_VBUS                        |
|              | A_VBUS_VLD Interrupt and B device attaches   | Go to A_HOST<br>Turn on Host mode                             |
| A_HOST       | Enumerate Device determine OTG Support.  |   |
|              | If A_VBUS_VLD/ Interrupt or A device is done and does not think it wants to do something soon or the B device disconnects  | Go to A_WAIT_VFALL<br>Turn off Host mode<br>Turn off DRV_VBUS |
|              | If the A device is finished with session or if the A device wants to allow the B device to take bus.   | Go to A_SUSPEND   |
|              | ID Interrupt or the B device disconnects   | Go to A_WAIT_BCON   |

Table continues on the next page...

**Table 48-131. State descriptions for the dual role A device flow (continued)**

| State        | Action  | Response                                 |
|--------------|---|--|
| A_SUSPEND    | If ID Interrupt, or if 150 ms B disconnect timeout (This timeout value could be longer) or if A_VBUS_VLD\ Interrupt | Go to A_WAIT_VFALL<br>Turn off DRV_VBUS  |
|              | If HNP enabled, and B disconnects in 150 ms then B device is becoming the host.                                     | Go to A_PERIPHERAL<br>Turn off Host mode |
|              | If A wants to start another session   | Go to A_HOST                             |
| A_PERIPHERAL | If ID Interrupt or if A_VBUS_VLD interrupt  | Go to A_WAIT_VFALL<br>Turn off DRV_VBUS. |
|              | If 3 –200 ms of Bus Idle  | Go to A_WAIT_BCON<br>Turn on Host mode   |
| A_WAIT_VFALL | If ID Interrupt or (A_SESS_VLD/ & b_conn/)  | Go to A_IDLE                             |

### 48.7.2 OTG dual role B device operation

A device is considered a B device if it is connected to the bus with a USB Type B cable or a USB Type Mini B cable.

A dual role B device operates as the following flow diagram and state description table illustrates.

**Figure 48-97. Dual role B device flow diagram**

**Table 48-132. State descriptions for the dual role B device flow**

| State        | Action   | Response   |
|--------------|--|--|
| B_IDLE       | If ID\ Interrupt.<br><br>A Type A cable has been plugged in and the device should now respond as a Type A device.                            | Go to A_IDLE   |
|              | If B_SESS_VLD Interrupt.<br><br>The A device has turned on VBUS and begins a session.  | Go to B_PERIPHERAL<br>Turn on DP_HIGH                        |
|              | If B application wants the bus and Bus is Idle for 2 ms and the B_SESS_END bit is set, the B device can perform an SRP.                      | Go to B_SRP_INIT<br>Pulse CHRG_VBUS<br>Pulse DP_HIGH 5-10 ms |
| B_SRP_INIT   | If ID\ Interrupt or SRP Done (SRP must be done in less than 100 ms.)   | Go to B_IDLE   |
| B_PERIPHERAL | If HNP enabled and the bus is suspended and B wants the bus, the B device can become the host.   | Go to B_WAIT_ACON<br>Turn off DP_HIGH                        |
| B_WAIT_ACON  | If A connects, an attach interrupt is received   | Go to B_HOST<br>Turn on Host Mode                            |
|              | If ID\ Interrupt or B_SESS_VLD/ Interrupt<br><br>If the cable changes or if VBUS goes away, the host doesn't support us.<br><br>Go to B_IDLE | Go to B_IDLE   |
|              | If 3.125 ms expires or if a Resume occurs  | Go to B_PERIPHERAL   |
| B_HOST       | If ID\ Interrupt or B_SESS_VLD\ Interrupt<br><br>If the cable changes or if VBUS goes away, the host doesn't support us.                     | Go to B_IDLE   |
|              | If B application is done or A disconnects  | Go to B_PERIPHERAL   |

# Chapter 49

## USB Device Charger Detection Module (USBDCD)

### 49.1 Preface

#### 49.1.1 References

The following publications are referenced in this document. For updates to these specifications, see <http://www.usb.org>.

- *USB Battery Charging Specification Revision 1.1, USB Implementers Forum*
- *Universal Serial Bus Specification Revision 2.0, USB Implementers Forum*

#### 49.1.2 Acronyms and abbreviations

The following table contains acronyms and abbreviations used in this document.

**Table 49-1. Acronyms and abbreviated terms**

| Term                      | Meaning   |
|---------------------------|---|
| FS                        | Full speed (12 Mbit/s)  |
| HS                        | High speed (480 Mbit/s)   |
| I <sub>DEV_DCHG</sub>     | Current drawn when the USB device is connected to a dedicated charging port |
| I <sub>DEV_HCHG_LFS</sub> | Current drawn when the USB device is connected to an FS charging host port  |
| I <sub>DM_SINK</sub>      | Current sink for the D- line  |
| I <sub>DP_SRC</sub>       | Current source for the D+ line  |
| I <sub>SUSP</sub>         | Current drawn when the USB device is suspended                              |
| LDO                       | Low dropout   |
| LS                        | Low Speed (1.5 Mbit/s)  |
| N/A                       | Not applicable  |
| OTG                       | On-The-Go   |

*Table continues on the next page...*

**Table 49-1. Acronyms and abbreviated terms (continued)**

| Term                 | Meaning  |
|----------------------|--|
| R <sub>DM_DWN</sub>  | D– pulldown resistance for data pin contact detect       |
| V <sub>DAT_REF</sub> | Data detect reference voltage for the voltage comparator |
| V <sub>DP_SRC</sub>  | Voltage source for the D+ line                           |
| V <sub>LGc</sub>     | Threshold voltage for logic high                         |

### 49.1.3 Glossary

The following table shows a glossary of terms used in this document.

**Table 49-2. Glossary of terms**

| Term        | Definition  |
|-------------|---|
| Transceiver | Module that implements the physical layer of the USB standard (FS or LS only).                          |
| PHY         | Module that implements the physical layer of the USB standard (HS capable).                             |
| Attached    | Device is physically plugged into USB port, but has <i>not enabled</i> either D+ or D– pullup resistor. |
| Connected   | Device is physically plugged into USB port, and has <i>enabled</i> either D+ or D– pullup resistor.     |
| Suspended   | After 3 ms of no bus activity, the USB device enters suspend mode.                                      |
| Component   | The hardware and software that make up a subsystem.   |

## 49.2 Introduction

### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The USBDCD module works with the USB transceiver to detect whether the USB device is attached to a charging port, either a dedicated charging port or a charging host. System software coordinates the detection activities of the module and controls an off-chip integrated circuit that performs the battery charging.

### 49.2.1 Block diagram

The following figure is a high level block diagram of the module.

**Figure 49-1. Block diagram**

The USBDCD module consists of two main blocks:

- A digital block provides the programming interface (memory-mapped registers) and includes the timer unit and the analog control unit.
- An analog block provides the circuitry for the physical detection of the charger, including the voltage source, current source, current sink, and voltage comparator circuitry.

## 49.2.2 Features

The USBDCD module offers the following features:

- Compliant with the latest industry standard specification: *USB Battery Charging Specification, Revision 1.1*
- Programmable timing parameters default to values required by the industry standards:
  - Having standard default values allows for easy configuration- simply set the clock frequency before enabling the module.
  - Programmability allows the flexibility to meet future updates of the standards.

## 49.2.3 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

**Table 49-3. Module modes and their conditions**

| Module mode | Description  | Conditions when used  |
|-------------|--|---|
| Enabled     | The module performs the charger detection sequence.        | System software should enable the module only when <i>all</i> of the following conditions are true: <ul style="list-style-type: none"> <li>The system uses a rechargeable battery.</li> <li>The device is being used in an FS USB device application.</li> <li>The device has detected that it is attached to the USB cable.</li> </ul> |
| Disabled    | The module is not active and is held in a low power state. | System software should disable the module when <i>either</i> of the following conditions is true: <ul style="list-style-type: none"> <li>The charger detect sequence is complete.</li> <li>The conditions for being enabled are not met.</li> </ul>   |
| Powered Off | The digital supply voltage <i>dvdd</i> is removed.         | Low system performance requirements allow putting the device into a very low-power stop mode.   |

Operating mode transitions are shown in the following table.

**Table 49-4. Entering and exiting module modes**

| Module mode | Entering   | Exiting   | Mode after exiting |
|-------------|--|---|--------------------|
| Enabled     | Set CONTROL[START].  | Set CONTROL[SR]. <sup>1</sup>   | Disabled           |
| Disabled    | Take <i>either</i> of the following actions: <ul style="list-style-type: none"> <li>Set CONTROL[SR].<sup>1</sup></li> <li>Reset the module. By default, the module is disabled.</li> </ul> | Set CONTROL[START].   | Enabled            |
| Powered Off | Perform the following actions: <ol style="list-style-type: none"> <li>Put the device into very low-power stop mode.</li> <li>Adjust the supply voltages.</li> </ol>                        | Perform the following actions: <ol style="list-style-type: none"> <li>Restore the supply voltages.</li> <li>Take the device out of very low-power stop mode.</li> </ol> | Disabled           |

1. The effect of setting the SR bit is immediate; that is, the module is disabled even if the sequence has not completed.

### 49.3 Module signal descriptions

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

**Table 49-5. Signal descriptions**

| Signal              | Description  | I/O |
|---------------------|--|-----|
| usb_dm              | USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus. | I/O |
| usb_dp              | USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus. | I/O |
| avdd33 <sup>1</sup> | 3.3 V regulated analog supply  | I   |
| avss                | Analog ground  | I   |
| dvss                | Digital ground   | I   |
| dvdd                | 1.2 V digital supply   | I   |

1. Voltage must be 3.3 V +/- 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] bit should not be set.

### NOTE

The transceiver module also interfaces to the usb\_dm and usb\_dp signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 specification and in [Application information](#).

## 49.4 Memory map/Register definition

This section describes the memory map and registers for the USBDCD module.

### USBDCD memory map

| Absolute address (hex) | Register name                     | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|-----------------------------------|-----------------|--------|-------------|-----------------------------|
| 4003_5000              | Control register (USBDCD_CONTROL) | 32              | R/W    | 0001_0000h  | <a href="#">49.4.1/1482</a> |
| 4003_5004              | Clock register (USBDCD_CLOCK)     | 32              | R/W    | 0000_00C1h  | <a href="#">49.4.2/1483</a> |
| 4003_5008              | Status register (USBDCD_STATUS)   | 32              | R      | 0000_0000h  | <a href="#">49.4.3/1485</a> |
| 4003_5010              | TIMER0 register (USBDCD_TIMER0)   | 32              | R/W    | 0010_0000h  | <a href="#">49.4.4/1486</a> |

### 49.4.1 Control register (USBDCD\_CONTROL)

Contains the control and interrupt bit fields.

Address: 4003\_5000h base + 0h offset = 4003\_5000h

**USBDCD\_CONTROL field descriptions**

| Field             | Description  |
|-------------------|--|
| 31–26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 25<br>SR          | Software Reset<br><br>Determines whether a software reset is performed.<br><br>0 Do not perform a software reset.<br>1 Perform a software reset.   |
| 24<br>START       | Start Change Detection Sequence<br><br>Determines whether the charger detection sequence is initiated.<br><br>0 Do not start the sequence. Writes of this value have no effect.<br>1 Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect. |
| 23–17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 16<br>IE          | Interrupt Enable<br><br>Enables/disables interrupts to the system.   |

*Table continues on the next page...*

### USBDCD\_CONTROL field descriptions (continued)

| Field            | Description  |
|------------------|--|
|                  | 0 Disable interrupts to the system.<br>1 Enable interrupts to the system.  |
| 15–9<br>Reserved | This field is reserved.  |
| 8<br>IF          | Interrupt Flag<br><br>Determines whether an interrupt is pending.<br><br>0 No interrupt is pending.<br>1 An interrupt is pending.                      |
| 7–1<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 0<br>IACK        | Interrupt Acknowledge<br><br>Determines whether the interrupt is cleared.<br><br>0 Do not clear the interrupt.<br>1 Clear the IF bit (interrupt flag). |

### 49.4.2 Clock register (USBDCD\_CLOCK)

Address: 4003\_5000h base + 4h offset = 4003\_5004h

### USBDCD\_CLOCK field descriptions

| Field               | Description   |
|---------------------|---|
| 31–12<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 11–2<br>CLOCK_SPEED | Numerical Value of Clock Speed in Binary  |

Table continues on the next page...

### USBDCD\_CLOCK field descriptions (continued)

| Field                   | Description   |
|-------------------------|---|
|                         | <p>The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when clock unit is MHz and 4 to 1023 when clock unit is kHz. Examples with CLOCK_UNIT = 1:</p> <ul style="list-style-type: none"> <li>• For 48 MHz: 0b00_0011_0000 (48) (Default)</li> <li>• For 24 MHz: 0b00_0001_1000 (24)</li> </ul> <p>Examples with CLOCK_UNIT = 0:</p> <ul style="list-style-type: none"> <li>• For 100 kHz: 0b00_0110_0100 (100)</li> <li>• For 500 kHz: 0b01_1111_0100 (500)</li> </ul> |
| <p>1<br/>Reserved</p>   | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| <p>0<br/>CLOCK_UNIT</p> | <p>Unit of Measurement Encoding for Clock Speed</p> <p>Specifies the unit of measure for the clock speed.</p> <p>0 kHz Speed (between 1 kHz and 1023 kHz)<br/>1 MHz Speed (between 1 MHz and 1023 MHz)</p>  |

### 49.4.3 Status register (USBDCD\_STATUS)

Provides the current state of the module for system software monitoring.

Address: 4003\_5000h base + 8h offset = 4003\_5008h

**USBDCD\_STATUS field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 22<br>ACTIVE      | Active Status Indicator<br><br>Indicates whether the sequence is running.<br><br>0 The sequence is not running.<br>1 The sequence is running. |
| 21<br>TO          | Timeout Flag<br><br>Indicates whether the detection sequence has passed the timeout threshold.  |

*Table continues on the next page...*

**USBDCD\_STATUS field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
|                   | 0 The detection sequence has not been running for over 1 s.<br>1 It has been over 1 s since the data pin contact was detected and debounced.  |
| 20<br>ERR         | Error Flag<br><br>Indicates whether there is an error in the detection sequence.<br><br>0 No sequence errors.<br>1 Error in the detection sequence. See the SEQ_STAT field to determine the phase in which the error occurred.  |
| 19–18<br>SEQ_STAT | Charger Detection Sequence Status<br><br>Indicates the status of the charger detection sequence.<br><br>00 The module is either not enabled, or the module is enabled but the data pins have not yet been detected.<br>01 Data pin contact detection is complete.<br>10 Charging port detection is complete.<br>11 Charger type detection is complete.  |
| 17–16<br>SEQ_RES  | Charger Detection Sequence Results<br><br>Reports how the charger detection is attached.<br><br>00 No results to report.<br>01 Attached to a standard host. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected.<br>10 Attached to a charging port. The exact meaning depends on bit 18: <ul style="list-style-type: none"> <li>• 0: Attached to either a charging host or a dedicated charger. The charger type detection has not completed.</li> <li>• 1: Attached to a charging host. The charger type detection has completed.</li> </ul> 11 Attached to a dedicated charger. |
| 15–0<br>Reserved  | This field is reserved.<br><br><b>NOTE:</b> Bits do not always read as 0.   |

**49.4.4 TIMER0 register (USBDCD\_TIMER0)**

TIMER0 has an TSEQ\_INIT field that represents the system latency in ms. Latency is measured from the time when VBUS goes active until the time system software initiates charger detection sequence in USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ\_INIT.

Valid values are 0–1023, however the USB Battery Charging Specification requires the entire sequence, including TSEQ\_INIT, to be completed in 1s or less.

Address: 4003\_5000h base + 10h offset = 4003\_5010h

**USBDCD\_TIMER0 field descriptions**

| Field              | Description   |
|--------------------|---|
| 31–26<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 25–16<br>TSEQ_INIT | Sequence Initiation Time<br>TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets the CONTROL[START] bit, the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1s or less.  |
| 15–12<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 11–0<br>TUNITCON   | Unit Connection Timer Elapse (in ms)<br>Displays the amount of elapsed time since the event of setting the START bit plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT<br>This timer enables compliance with the maximum time allowed to connect T <sub>UNIT_CON</sub> under the USB Battery Charging Specification, v1.1. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR].<br>The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of 0xFF (4095 ms). The timer does not rollover to zero. A software reset clears the timer. |

**49.4.5 TIMER1 register (USBDCD\_TIMER1)**

TIMER1 contains timing parameters. Note that register values can be written that are not compliant with the USB Battery Charging Specification v1.1, so care should be taken when overwriting the default values.

Address: 4003\_5000h base + 14h offset = 4003\_5014h

**USBDCD\_TIMER1 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

*Table continues on the next page...*

### USBDCD\_TIMER1 field descriptions (continued)

| Field              | Description   |
|--------------------|---|
| 25–16<br>TDCD_DBNC | Time Period to Debounce D+ Signal<br>Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See "Debouncing the data pin contact"<br>Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 10 ms. |
| 15–10<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 9–0<br>TVDPSRC_ON  | Time Period Comparator Enabled<br>This timing parameter is used after detection of the data pin. See "Charging Port Detection".<br>Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms.   |

### 49.4.6 TIMER2 register (USBDCD\_TIMER2)

TIMER2 contains timing parameters.

#### NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification v1.1, so care should be taken when overwriting the default values.

Address: 4003\_5000h base + 18h offset = 4003\_5018h

|       |    |    |    |    |    |    |             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |   |   |   |   |   |   |   |   |   |   |

### USBDCD\_TIMER2 field descriptions

| Field                | Description  |
|----------------------|--|
| 31–26<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 25–16<br>TVDPSRC_CON | Time Period Before Enabling D+ Pullup<br>Sets the time period (ms) that the module waits after charging port detection before system software must enable the D+ pullup to connect to the USB host. Valid values are 1–1023, but the USB Battery Charging Specification requires a minimum value of 40 ms. |
| 15–4<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3–0<br>CHECK_DM      | Time Before Check of D– Line<br>Sets the amount of time (in ms) that the module waits after the device connects to the USB bus until checking the state of the D– line to determine the type of charging port. See "Charger Type Detection."<br>Valid values are 1–15ms.                                   |

## 49.5 Functional description

The sequence of detecting the presence of charging port and type of charging port involves several hardware components, coordinated by system software. This collection of interacting hardware and software is called the USB Battery Charging Subsystem. The following figure shows the USBDCD module as a component of the subsystem. The following table describes the components.

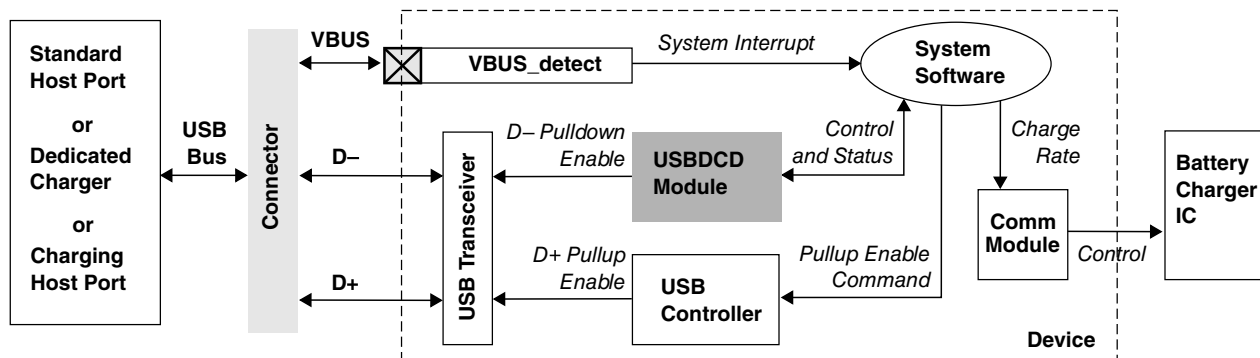

Figure 49-8. USB battery charging subsystem

Table 49-13. USB battery charger subsystem components

| Component               | Description  |         |                                    |                    |              |                    |               |                         |               |
|-------------------------|--|---------|------------------------------------|--------------------|--------------|--------------------|---------------|-------------------------|---------------|
| Battery Charger IC      | The external battery charger IC regulates the charge rate to the rechargeable battery. System software is responsible for communicating the appropriate charge rates.  |         |                                    |                    |              |                    |               |                         |               |
|                         | <table border="1"> <thead> <tr> <th>Charger</th> <th>Maximum current drawn<sup>1</sup></th> </tr> </thead> <tbody> <tr> <td>Standard host port</td> <td>up to 500 mA</td> </tr> <tr> <td>Charging host port</td> <td>up to 1500 mA</td> </tr> <tr> <td>Dedicated charging port</td> <td>up to 1800 mA</td> </tr> </tbody> </table>   | Charger | Maximum current drawn <sup>1</sup> | Standard host port | up to 500 mA | Charging host port | up to 1500 mA | Dedicated charging port | up to 1800 mA |
| Charger                 | Maximum current drawn <sup>1</sup>   |         |                                    |                    |              |                    |               |                         |               |
| Standard host port      | up to 500 mA   |         |                                    |                    |              |                    |               |                         |               |
| Charging host port      | up to 1500 mA  |         |                                    |                    |              |                    |               |                         |               |
| Dedicated charging port | up to 1800 mA  |         |                                    |                    |              |                    |               |                         |               |
|                         | 1. If the USB host has suspended the USB device, system software must configure the system to limit the current drawn from the USB bus to 2.5 mA or less.  |         |                                    |                    |              |                    |               |                         |               |
| Comm Module             | A communications module on the device can be used to control the charge rate of the battery charger IC.  |         |                                    |                    |              |                    |               |                         |               |
| System software         | Coordinates the detection activities of the subsystem.   |         |                                    |                    |              |                    |               |                         |               |
| USB Controller          | The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it.<br><br><b>NOTE:</b> The USB controller must be used only for USB device applications when using the USBDCD module. For USB host applications, the USBDCD module must be disabled. |         |                                    |                    |              |                    |               |                         |               |

Table continues on the next page...

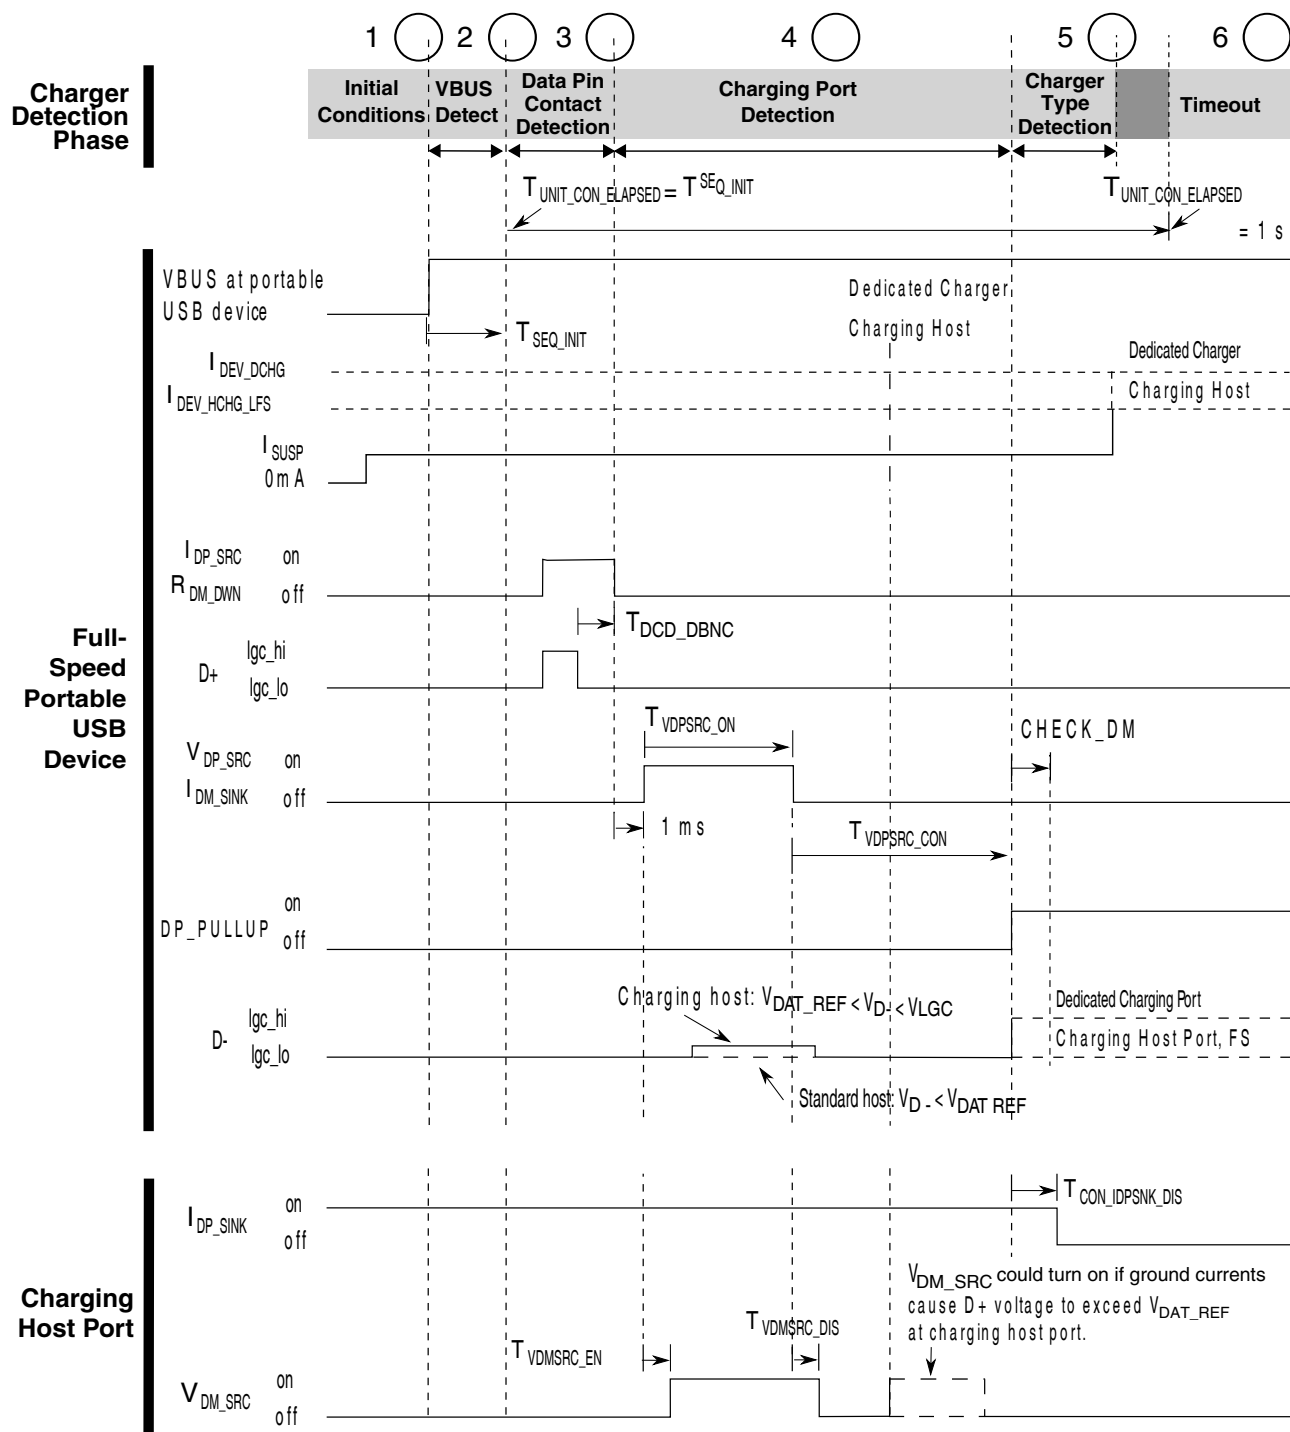

**Table 49-13. USB battery charger subsystem components (continued)**

| Component       | Description   |
|-----------------|---|
| USB Transceiver | <p>The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus.</p> <p>The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence. The D+ pullup enable is output from the USB controller and is under software control. The USBDCD module controls the D–pulldown enable.</p> |
| USBDCD Module   | Detects whether the device has been plugged into either a standard host port, a charging host port, or a dedicated charger.   |
| VBUS_detect     | This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low power mode on being plugged into the USB port, this interrupt should also be a low power wake up source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.  |

1. If the USB host has suspended the USB device, system software must configure the system to limit the current drawn from the USB bus to 2.5 mA or less.

### 49.5.1 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the USB Battery Charging Specification v1.1.

**Figure 49-9. Full speed charger detection timing**

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

**Table 49-14. Overview of the charger detection sequence**

| Phase |                            | Overview description  | Full description                                   |
|-------|----------------------------|---|--|
| 1     | Initial Conditions         | Initial system conditions that need to be met before the detection sequence is initiated.   | <a href="#">Initial System Conditions</a>          |
| 2     | VBUS Detection             | System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.   | <a href="#">VBUS contact detection</a>             |
| 3     | Data Pin Contact Detection | The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.   | <a href="#">Data pin contact detection</a>         |
| 4     | Charging Port Detection    | The USBDCD module detects if the port is a standard host or either type of charging port, that is charging host or dedicated charger.     | <a href="#">Charging port detection</a>            |
| 5     | Charger Type Detection     | The USBDCD module detects the type of charging port, if applicable.   | <a href="#">Charger type detection</a>             |
| 6     | Sequence Timeout           | The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software. | <a href="#">Charger detection sequence timeout</a> |

Timing parameter values used in this module are listed in the following table.

**Table 49-15. Timing parameters for the charger detection sequence**

| Parameter                 | USB Battery Charging Spec | Module default    | Module programmable range |
|---------------------------|---------------------------|-------------------|---------------------------|
| $T_{DCD\_DBNC}^1$         | 10 ms min (no max)        | 10 ms             | 0– 1023 ms                |
| $T_{VDPSRC\_ON}^1$        | 40 ms min (no max)        | 40 ms             | 0 –1023 ms                |
| $T_{VDPSRC\_CON}^1$       | 40 ms min (no max)        | 40 ms             | 0 –1023 ms                |
| CHECK_DM                  | N/A                       | 1 ms              | 0– 15 ms                  |
| $T_{SEQ\_INIT}$           | N/A                       | 16 ms             | 0 –1023 ms                |
| $T_{UNIT\_CON}^1$         | 1 s                       | N/A               | N/A                       |
| $T_{VDMSRC\_EN}^1$        | 1– 20 ms                  | From the USB host | N/A                       |
| $T_{VDMSRC\_DIS}^1$       | 0 –20 ms                  | From the USB host | N/A                       |
| $T_{CON\_IDPSINK\_DIS}^1$ | 0– 20 ms                  | From the USB host | N/A                       |

1. This parameter is defined by the *USB Battery Charging Specification, v1.1*.

### 49.5.1.1 Initial System Conditions

The USBDCD module can be used only with FS USB device applications using a rechargeable battery. That is, it cannot be used with USB applications that are HS, LS, host, or OTG. In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low power mode subsequently enters run mode upon being plugged into the USB bus.

### 49.5.1.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS\_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear the bit if software polling method is used .
5. Set CONTROL[START] to start the charger detection sequence.

### 49.5.1.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ signal. USB plugs and receptables are designed such that when the plug is inserted into the receptable, the power pins make contact before the data pins make contact. See the following figure.

**Figure 49-10. Relative pin positions in USB plugs and receptacles**

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptacle. Delays of several hundred milliseconds are possible.

#### 49.5.1.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in [Initial System Conditions](#), the USBDCD module turns on the  $I_{DP\_SRC}$  current source and enables the  $R_{DM\_DWN}$  pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the  $T_{DCD\_DBNC}$  debounce time interval. By default,  $T_{DCD\_DBNC}$  is 10 ms, but it can be programmed in the `TIMER0[TDCD_DBNC]` field. See the description of the `TIMER0` Register for register information.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see [Success in detecting data pin contact \(phase completion\)](#)).
- A timeout occurs (see [Charger detection sequence timeout](#)).

#### 49.5.1.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the `STATUS` register to reflect phase completion (See [Table 49-18](#) for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See [Charging port detection](#).)

### 49.5.1.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source  $V_{DP\_SRC}$  connects to the D+ line
- The current sink  $I_{DM\_SINK}$  connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage  $V_{DAT\_REF}$ .

After a time of  $T_{VDPSRC\_ON}$ , the module samples the D– line. The  $T_{VDPSRC\_ON}$  parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

**Table 49-16. Sampling D– in the charging port detection phase**

| If the voltage on D- is...               | Then...   | See...   |
|--|---|--|
| Below $V_{DAT\_REF}$                     | The port is a <i>standard host</i> that does not support the USB Battery Charging Specification v1.1. | <a href="#">Standard host port</a>               |
| Above $V_{DAT\_REF}$ but below $V_{LGC}$ | The port is a <i>charging port</i> .  | <a href="#">Charging port</a>                    |
| Above $V_{LGC}$                          | This is an error condition.   | <a href="#">Error in charging port detection</a> |

#### 49.5.1.4.1 Standard host port

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the  $T_{VDPSRC\_CON}$  interval to elapse:

- Updates the STATUS register to reflect that a standard host has been detected with  $SEQ\_RES = 01$ . See [Table 49-18](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software should perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see [Table 49-13](#).

#### 49.5.1.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the  $T_{VDPSRC\_CON}$  interval has elapsed before it does the following:

- Updates the STATUS register to reflect that a charging port has been detected with  $SEQ\_RES = 10$ . See [Table 49-18](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Issue a command to the USB controller to pullup the USB D+ line.
4. Wait for the module to complete the final phase of the sequence. See [Charger type detection](#).

#### 49.5.1.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with  $SEQ\_RES = 00$ . See [Table 49-18](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the  $T_{VDPSRC\_CON}$  interval to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

### 49.5.1.5 Charger type detection

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK\_DM timer counting down the time interval programmed in the TIMER2[CHECK\_DM] field.

After the CHECK\_DM time has elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

**Table 49-17. Sampling D– in the charger type detection phase**

| If the voltage on D– is... | Then...   | See...                                  |
|----------------------------|---|---|
| High                       | The port is a <i>dedicated charging port</i> . <sup>1</sup> | <a href="#">Dedicated charging port</a> |
| Low                        | The port is a <i>charging host port</i> . <sup>2</sup>      | <a href="#">Charging host port</a>      |

1. In a dedicated charger, the D+ and D– lines are shorted together through a small resistor.
2. In a charging host port, the D+ and D– lines are not shorted.

#### 49.5.1.5.1 Dedicated charging port

For a dedicated charger, the module does the following:

- Updates the STATUS register to reflect that a dedicated charger has been detected with SEQ\_RES = 11. See [Table 49-18](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] bit.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.

2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.
6. Communicate the appropriate charge rate to the external battery charger IC; see [Table 49-13](#).

#### 49.5.1.5.2 Charging host port

For a charging host port, the module does the following:

- Updates the STATUS register to reflect that a charging host port has been detected with SEQ\_RES = 10. See [Table 49-18](#) for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see [Table 49-13](#).

#### 49.5.1.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification, v1.1* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] bit, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occurred. See [Table 49-18](#) for field values.
- Sets the CONTROL[IF] bit.
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting the CONTROL[SR] bit.
- The Unit Connection Timer continues counting. See the description of the TIMER0 Register.

At this point, control has been passed to system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software should:

1. Read the STATUS register.
2. Set the CONTROL[IACK] bit to acknowledge the interrupt.
3. Set the CONTROL[SR] bit to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the  $V_{BUS\_DETECT}$  input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[T<sub>UNITCON</sub>] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the T<sub>UNITCON</sub> register field will stop incrementing when it reaches its maximum value so it will not rollover to zero and start counting up again.

## 49.5.2 Interrupts and events

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

**Table 49-18. Events triggering an interrupt by sequence phase**

| Sequence phase          | Event          | Event description   | STATUS fields <sup>1</sup>   | Phase description                   |
|-------------------------|----------------|---|--|-------------------------------------|
| Data Pin Detection      | Phase Complete | The module has detected data pin contact.<br><i>No interrupt occurs: CONTROL[IF] = 0.</i>   | ERR = 0<br>SEQ_STAT = 01<br>SEQ_RES = 00<br>TO = 0   | VBUS contact detection              |
| Charging Port Detection | Phase Complete | The module has completed the process of identifying if the USB port is a charging port or not.  | ERR = 0<br>SEQ_STAT = 10<br>SEQ_RES = 01 or 10<br>TO = 0                                     | Charging port detection             |
|                         | Error          | The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.  | ERR = 1<br>SEQ_STAT = 10<br>SEQ_RES = 00<br>TO = 0   | Error in charging port detection    |
| Charger Type Detection  | Phase Complete | The module has completed the process of identifying the charger type detection.<br><b>Note:</b> The ERR flag always reads zero because no known error conditions are checked during this phase. | ERR = 0<br>SEQ_STAT = 11<br>SEQ_RES = 11 or 10<br>TO = 0                                     | Charger type detection              |
| Sequence Timeout        | Error          | The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.   | ERR = 1<br>SEQ_STAT = last value <sup>2</sup><br>SEQ_RES = last value <sup>2</sup><br>TO = 1 | Charger detection sequence timeout. |

1. See the description of the Status register for register information.

2. The SEQ\_STAT and SEQ\_RES fields retain the values held at the time of the timeout error.

### 49.5.2.1 Interrupt Handling

Software can read which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] bit is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

### 49.5.3 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

#### 49.5.3.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

#### 49.5.3.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

**Table 49-19. Software reset and register fields affected**

| Register             | Fields affected | Fields not affected |
|----------------------|-----------------|---------------------|
| CONTROL <sup>1</sup> | IF              | IE, START           |
| STATUS               | All             | None                |
| CLOCK                | None            | All                 |
| TIMER <sub>n</sub>   | TUNITCON        | All other           |

1. CONTROL[SR] and CONTROL[ IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1), a software reset stops the sequence.

## Note

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

## 49.6 Initialization information

This module has been designed for minimal configuration while retaining significant programmability. The CLOCK register needs to be initialized to the actual system clock frequency, unless the default value already matches the system requirements.

The other registers generally do not need to be modified, because they default to values that comply with the USB Battery Charging Specification v1.1. However, several timing parameters can be changed for a great deal of flexibility if a particular system requires it.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

## 49.7 Application information

This section provides application information.

### 49.7.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

### 49.7.2 Dead or weak battery

According to the USB Battery Charging Specification v1.1, a USB device with a dead, weak, or missing battery that is attached to a charging port can remain attached indefinitely drawing up to 1.5A, until the battery is charged to the point that the USB device can connect.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the D+ line high after the USBDCD module has determined that the device is attached to a charging port.

The module is also compatible with systems that do check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging at 1.5A. Once the battery is charged to the good battery threshold, software can then connect to the USB host by pulling the D+ line high.

### 49.7.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in [Software reset](#).

# Chapter 50

## USB Voltage Regulator (VREG)

### 50.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

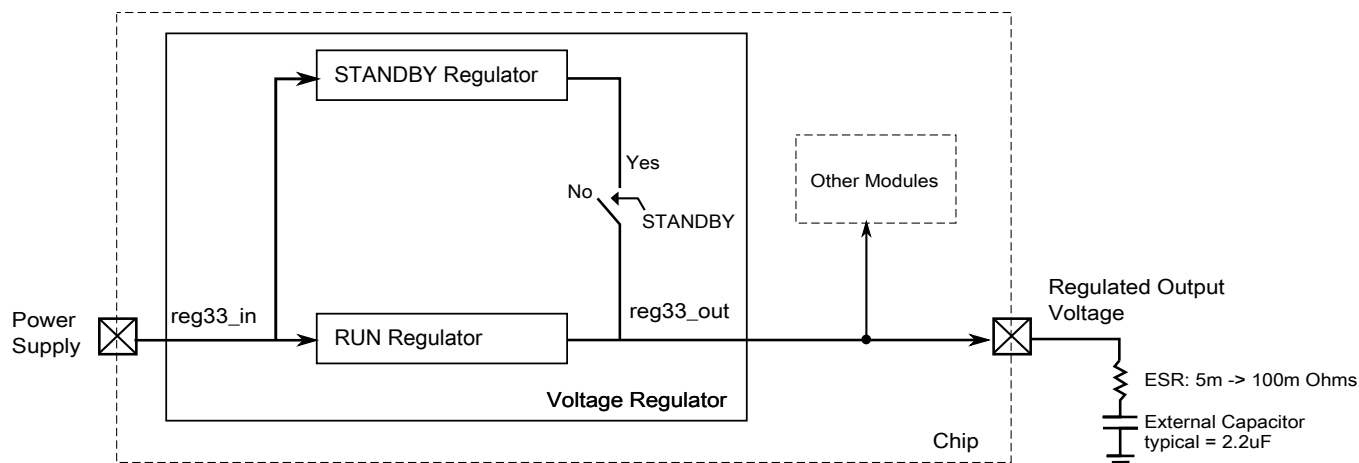

The USB Voltage Regulator module is a LDO linear voltage regulator to provide 3.3V power from an input power supply varying from 2.7 V to 5.5 V. It consists of one 3.3 V power channel. When the input power supply is below 3.6 V, the regulator goes to pass-through mode. The following figure shows the ideal relation between the regulator output and input power supply.

**Figure 50-1. Ideal Relation Between the Regulator Output and Input Power Supply**

## 50.1.1 Overview

A simplified block diagram for the USB Voltage Regulator module is shown below.

**Figure 50-2. USB Voltage Regulator Block Diagram**

This module uses 2 regulators in parallel. In run mode, the RUN regulator with the bandgap voltage reference is enabled and can provide up to 120 mA load current. In run mode, the STANDBY regulator and the low power reference are also enabled, but a switch disconnects its output from the external pin. In STANDBY mode, the RUN regulator is disabled and the STANDBY regulator output is connected to the external pin. Internal power mode signals control whether the module is in RUN or STANDBY mode.

## 50.1.2 Features

- Low drop-out linear voltage regulator with one power channel (3.3 V).
- Low drop-out voltage: 300 mV.
- Output current: 120 mA.
- Three different power modes: RUN, STANDBY and SHUTDOWN.
- Low quiescent current in RUN mode.
  - Typical value is around 120  $\mu$ A (one thousand times smaller than the maximum load current).
- Very low quiescent current in STANDBY mode.
  - Typical value is around 1  $\mu$ A.
- Automatic current limiting if the load current is greater than 290 mA.

- Automatic power-up once some voltage is applied to the regulator input.
- Pass-through mode for regulator input voltages less than 3.6 V
- Small output capacitor: 2.2  $\mu$ F
- Stable with aluminum, tantalum or ceramic capacitors.

### 50.1.3 Modes of Operation

The regulator has these power modes:

- **RUN**—The regulating loop of the RUN regulator and the STANDBY regulator are active, but the switch connecting the STANDBY regulator output to the external pin is open.
- **STANDBY**—The regulating loop of the RUN regulator is disabled and the standby regulator is active. The switch connecting the STANDBY regulator output to the external pin is closed.
- **SHUTDOWN**—The module is disabled.

The regulator is enabled by default. This means that once the power supply is provided, the module power-up sequence to RUN mode starts.

## 50.2 USB Voltage Regulator Module Signal Descriptions

The following table shows the external signals for the regulator.

**Table 50-1. USB Voltage Regulator Module Signal Descriptions**

| Signal    | Description              | I/O |
|-----------|--------------------------|-----|
| reg33_in  | Unregulated power supply | I   |
| reg33_out | Regulator output voltage | O   |

# Chapter 51

## USB High Speed OTG Controller (USBHS)

### 51.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes the USB high speed OTG controller (USBHS), which implements many industry standards. However, it is beyond the scope of this document to document the intricacies of these standards. Instead, you should refer to the governing specifications. Readers of this chapter are assumed to be fluent in the operation and requirements of a USB network.

Visit the USB Implementers Forum web page at <http://www.usb.org/developers/docs> for:

- *Universal Serial Bus Specification, Revision 2.0*
- *On-The-Go Supplement to the USB 2.0 Specification, Revision 1.0a*

Visit the Intel USB specifications web page at <http://www.intel.com/technology/usb/ehcispec> for:

- *Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 1.0*

Visit the ULPI web page at <http://www.ulpi.org> for:

- *UTMI+ Specification, Revision 1.0*
- *UTMI Low Pin Interface (ULPI) Specification, Revision 1.1*

## 51.1.1 Overview

The USB high speed OTG controller (USBHS) is a USB 2.0-compliant serial interface engine for implementing a USB interface. The registers and data structures are based on the *Enhanced Host Controller Interface Specification for Universal Serial Bus* (EHCI) from Intel Corporation. The USBHS module can act as a host, a device, or an On-The-Go negotiable host/device on the USB bus.

The USBHS controller interfaces to the processor's core. The controller is programmable to support host or device operations under firmware control. The ULPI interface supports high-speed (HS) applications, as well as lower speeds.

## 51.1.2 Features

The USB On-The-Go module includes these features:

- Complies with USB specification rev 2.0
- USB host mode
  - Supports enhanced-host-controller interface (EHCI).
  - Supported by Linux and other commercially available operating systems.
- USB device mode
  - Supports full-speed/high-speed operation via an external ULPI transceiver.
  - Supports one upstream facing port.
  - Supports four programmable, bidirectional USB endpoints, including endpoint 0. See endpoint configurations:

**Table 51-1. Endpoint Configurations**

| Endpoint | Type          | FIFO Size | Data Transfer           | Comments  |
|----------|---------------|-----------|-------------------------|-----------|
| 0        | Bidirectional | Variable  | Control                 | Mandatory |
| 1-3      | IN or OUT     | Variable  | Ctrl, Int, Bulk, or Iso | Optional  |

- Suspend mode/low power
  - As host, firmware can suspend individual devices or the entire USB and disable chip clocks for low-power operation
  - Device supports low-power suspend

- Remote wake-up supported for host and device
- Integrated with the processor's low power modes
- Support for off-chip HS/FS/LS transceiver
  - External ULPI transceiver supports high speed (480 Mbps), full speed, and low speed operation in host mode, and high-speed and full-speed operation in device mode
  - Interface uses 8-bit single-data-rate ULPI data bus
  - ULPI PHY supplies a 60 MHz USB reference clock input to the processor

### 51.1.3 Modes of Operation

The USBHS module has two basic operating modes: host and device. Selection of operating mode is accomplished via the USBMODE[CM] bit field.

Speed selection is auto-detected at connect time using enumeration procedures in the USB network. The USBHS module provides these operation modes:

- USB disabled. In this mode, the USBHS's datapath does not accept transactions received on the USB interface.
- USB enabled. In this mode, the USB host's datapath is enabled to accept transactions received on the USB interface.
- USB enabled, low-power modes.

## 51.2 External Signal Description

This table describes the external signal functionality of the USBHS module.

**Table 51-2. USBHS Signal Descriptions**

| Signal   | I/O | Description                                  |
|----------|-----|--|
| ULPI_CLK | I   | 60 MHz clock input from the ULPI transceiver |

*Table continues on the next page...*

**Table 51-2. USBHS Signal Descriptions  
(continued)**

| Signal         | I/O                      | Description   |   |   |               |                          |
|----------------|--------------------------|---|---|---|---------------|--------------------------|
| ULPI_DIR       | I                        | Direction. ULPI_DIR controls data bus direction. When PHY has data to transfer to USB port, it drives ULPI_DIR high to take ownership of the bus. When the PHY has no data to transfer, it drives ULPI_DIR low and monitors the bus for link activity. The PHY pulls ULPI_DIR high when the interface cannot accept data from the link. For example, when PHY's PLL is not stable.  |   |   |               |                          |
|                |                          | <table border="0"> <tr> <td><b>State Meaning</b></td> <td>Asserted—PHY has data to transfer to the link.<br/>Negated—PHY has no data to transfer.</td> </tr> <tr> <td><b>Timing</b></td> <td>Synchronous to ULPI_CLK.</td> </tr> </table>   | <b>State Meaning</b>  | Asserted—PHY has data to transfer to the link.<br>Negated—PHY has no data to transfer.  | <b>Timing</b> | Synchronous to ULPI_CLK. |
|                |                          | <b>State Meaning</b>  | Asserted—PHY has data to transfer to the link.<br>Negated—PHY has no data to transfer.  |   |               |                          |
| <b>Timing</b>  | Synchronous to ULPI_CLK. |   |   |   |               |                          |
|                |                          |   |   |   |               |                          |
| ULPI_NXT       | I                        | Next data. PHY asserts ULPI_NXT to throttle data. When USB port sends data to the PHY, ULPI_NXT indicates when PHY accepts the current byte. The USB port places the next byte on the data bus in the following clock cycle. When the PHY sends data to USB port, ULPI_NXT indicates when a new byte is available for USB port to consume.  |   |   |               |                          |
|                |                          | <table border="0"> <tr> <td><b>State Meaning</b></td> <td>Asserted—PHY is ready to transfer byte.<br/>Negated—PHY is not ready.</td> </tr> <tr> <td><b>Timing</b></td> <td>Synchronous to ULPI_CLK.</td> </tr> </table>   | <b>State Meaning</b>  | Asserted—PHY is ready to transfer byte.<br>Negated—PHY is not ready.  | <b>Timing</b> | Synchronous to ULPI_CLK. |
|                |                          | <b>State Meaning</b>  | Asserted—PHY is ready to transfer byte.<br>Negated—PHY is not ready.  |   |               |                          |
| <b>Timing</b>  | Synchronous to ULPI_CLK. |   |   |   |               |                          |
|                |                          |   |   |   |               |                          |
| ULPI_STP       | O                        | Stop. ULPI_STP indicates the end of a transfer on the bus.  |   |   |               |                          |
|                |                          | <table border="0"> <tr> <td><b>State Meaning</b></td> <td>Asserted—USB asserts this signal for one clock cycle to stop the data stream currently on the bus. If the USB port sends data to the PHY, ULPI_STP indicates the last data byte was previously on the bus. If the PHY is sending data to the USB port, ULPI_STP forces the PHY to end its transfer, deassert ULPI_DIR, and relinquish control of the data bus to the USB port.<br/>Negated—Indicates normal operation.</td> </tr> <tr> <td><b>Timing</b></td> <td>Synchronous to ULPI_CLK</td> </tr> </table> | <b>State Meaning</b>  | Asserted—USB asserts this signal for one clock cycle to stop the data stream currently on the bus. ## 51.3 Memory Map/Register Definition

This section provides the memory map and detailed descriptions of the USBHS registers.

**Table 51-3. USBHS Register Overview**

| Address  | Register                                | EHCI <sup>1</sup> | H/D <sup>2</sup> |
|--|---|-------------------|------------------|
| <b>Module Identification Registers:</b> Declare the slave interface presence and include a table of the hardware configuration parameters. |   |                   |                  |
| 0x000  | Identification Register (ID)            | N                 | H/D              |
| 0x004  | General Hardware Parameters (HWGENERAL) | N                 | H/D              |

*Table continues on the next page...*

**Table 51-3. USBHS Register Overview  
(continued)**

| Address  | Register  | EHCI <sup>1</sup> | H/D <sup>2</sup> |
|--|---|-------------------|------------------|
| 0x008  | Host Hardware Parameters (HWHOST)                   | N                 | H/D              |
| 0x00C  | Device Hardware Parameters (HWDEVICE)               | N                 | D                |
| 0x010  | TX Buffer Hardware Parameters (HWTXBUF)             | N                 | H/D              |
| 0x014  | RX Buffer Hardware Parameters (HWRXBUF)             | N                 | H/D              |
| <b>Device/Host Timer Registers:</b> Used by host/device controller drivers to measure time-related activities.                       |   |                   |                  |
| 0x080  | General Purpose Timer 0 Load (GPTIMER0LD)           | N                 | H/D              |
| 0x084  | General Purpose Timer 0 Control (GPTIMER0CTL)       | N                 | H/D              |
| 0x088  | General Purpose Timer 1 Load (GPTIMER1LD)           | N                 | H/D              |
| 0x08C  | General Purpose Timer 1 Control (GPTIMER1CTL)       | N                 | H/D              |
| <b>Capability Registers:</b> Specifies software limits, restrictions, and capabilities of the host/device controller implementation. |   |                   |                  |
| 0x100  | Host Interface Version Number (HCVERSION)           | Y                 | H                |
| 0x103  | Capability Register Length (CAPLENGTH)              | Y                 | H/D              |
| 0x104  | Host Structural Parameters (HCSPARAMS)              | Y                 | H                |
| 0x108  | Host Capability Parameters (HCCPARAMS)              | Y                 | H                |
| 0x122  | Device Interface Version Number (DCVERSION)         | N                 | D                |
| 0x124  | Device Capability Parameters (DCCPARAMS)            | N                 | D                |
| <b>Operational Registers:</b> Comprised of dynamic control or status registers.  |   |                   |                  |
| 0x140  | USB Command (USBCMD)                                | Y                 | H/D              |
| 0x144  | USB Status (USBSTS)                                 | Y                 | H/D              |
| 0x148  | USB Interrupt Enable (USBINTR)                      | Y                 | H/D              |
| 0x14C  | USB Frame Index (FRINDEX)                           | Y                 | H/D              |
| 0x154  | Periodic Frame List Base Address (PERIODICLISTBASE) | Y                 | H                |
| 0x154  | Device Address (DEVICEADDR)                         | N                 | D                |
| 0x158  | Current Asynchronous List Address (ASYNCLISTADDR)   | Y                 | H                |
| 0x158  | Address at Endpoint List (EPLISTADDR)               | N                 | D                |
| 0x15C  | Host TT Asynchronous Buffer Control (TTCTRL)        | N                 | H                |
| 0x160  | Master Interface Data Burst Size (BURSTSIZE)        | N                 | H/D              |
| 0x164  | Host Transmit FIFO Tuning Control (TXFILLTUNING)    | N                 | H                |
| 0x170  | ULPI Register Access (ULPI_VIEWPORT)                | N                 | H/D              |
| 0x180  | Configure Flag Register (CONFIGFLAG)                | Y                 | H/D              |
| 0x184  | Port Status/Control (PORTSC1)                       | Y                 | H/D              |
| 0x1A4  | On-The-Go Status and Control (OTGSC)                | N                 | H/D              |
| 0x1A8  | USB Mode Register (MODE)                            | N                 | H/D              |
| 0x1AC  | Endpoint Setup Status Register (EPSETUPSR)          | N                 | D                |
| 0x1B0  | Endpoint Initialization (EPRIME)                    | N                 | D                |
| 0x1B4  | Endpoint De-initialize (EPFLUSH)                    | N                 | D                |
| 0x1B8  | Endpoint Status Register (EPSR)                     | N                 | D                |
| 0x1BC  | Endpoint Complete (EPCOMPLETE)                      | N                 | D                |

Table continues on the next page...

**Table 51-3. USBHS Register Overview  
(continued)**

| Address | Register                            | EHCI <sup>1</sup> | H/D <sup>2</sup> |
|---------|-------------------------------------|-------------------|------------------|
| 0x1C0   | Endpoint Control Register 0 (EPCR0) | N                 | D                |
| 0x1C4   | Endpoint Control Register 1 (EPCR1) | N                 | D                |
| 0x1C8   | Endpoint Control Register 2 (EPCR2) | N                 | D                |
| 0x1CC   | Endpoint Control Register 3 (EPCR3) | N                 | D                |

1. Indicates if the register is present in the EHCI specification.
2. Indicates if the register is available in host and/or device modes.

### USBHS memory map

| Absolute address (hex) | Register name   | Width (in bits) | Access      | Reset value | Section/page                 |
|------------------------|---|-----------------|-------------|-------------|------------------------------|
| 4003_4000              | Identification Register (USBHS_ID)  | 32              | R           | E461_FA05h  | <a href="#">51.3.1/1516</a>  |

### 51.3.1 Identification Register (USBHS\_ID)

The ID register provides a simple way to determine if the module is provided in the system. The ID register identifies the module and its revision.

Address: 4003\_4000h base + 0h offset = 4003\_4000h

|       |           |     |    |         |    |    |    |          |    |    |    |     |    |    |    |    |
|-------|-----------|-----|----|---------|----|----|----|----------|----|----|----|-----|----|----|----|----|
| Bit   | 31        | 30  | 29 | 28      | 27 | 26 | 25 | 24       | 23 | 22 | 21 | 20  | 19 | 18 | 17 | 16 |
| R     | VERSIONID |     |    | VERSION |    |    |    | REVISION |    |    |    | TAG |    |    |    |    |
| W     |           |     |    |         |    |    |    |          |    |    |    |     |    |    |    |    |
| Reset | 1         | 1   | 1  | 0       | 0  | 1  | 0  | 0        | 0  | 1  | 1  | 0   | 0  | 0  | 0  | 1  |
| Bit   | 15        | 14  | 13 | 12      | 11 | 10 | 9  | 8        | 7  | 6  | 5  | 4   | 3  | 2  | 1  | 0  |
| R     | 1         | NID |    |         |    |    |    | 0        | ID |    |    |     |    |    |    |    |
| W     |           |     |    |         |    |    |    |          |    |    |    |     |    |    |    |    |
| Reset | 1         | 1   | 1  | 1       | 1  | 0  | 1  | 0        | 0  | 0  | 0  | 0   | 0  | 1  | 0  | 1  |

#### USBHS\_ID field descriptions

| Field              | Description |
|--------------------|-------------|
| 31–29<br>VERSIONID | Version ID  |

Table continues on the next page...

**USBHS\_ID field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
|                   | Internal version counter.   |
| 28–25<br>VERSION  | Version<br>Version of the module.   |
| 24–21<br>REVISION | Revision<br>Revision number of the module.  |
| 20–16<br>TAG      | Tag<br>Tag of the module.   |
| 15–14<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 1. |
| 13–8<br>NID       | Ones complement version of ID.  |
| 7–6<br>Reserved   | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 5–0<br>ID         | Configuration number<br>This number is set to 0x05.   |

### 51.3.2 General Hardware Parameters Register (USBHS\_HWGENERAL)

The HWGENERAL register contains parameters defining the particular implementation of the module. These values depend on the configuration of the controller chosen by the manufacturer for each product.

Address: 4003\_4000h base + 4h offset = 4003\_4004h

|       |          |    |    |    |    |    |      |    |    |      |    |          |    |    |    |    |
|-------|----------|----|----|----|----|----|------|----|----|------|----|----------|----|----|----|----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25   | 24 | 23 | 22   | 21 | 20       | 19 | 18 | 17 | 16 |
| R     | 0        |    |    |    |    |    |      |    |    |      |    |          |    |    |    |    |
| W     | [Shaded] |    |    |    |    |    |      |    |    |      |    |          |    |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0    | 0  | 0  | 0    | 0  | 0        | 0  | 0  | 0  | 0  |
| Bit   | 15       | 14 | 13 | 12 | 11 | 10 | 9    | 8  | 7  | 6    | 5  | 4        | 3  | 2  | 1  | 0  |
| R     | 0        |    |    |    | SM |    | PHYM |    |    | PHYW |    | Reserved |    |    |    |    |
| W     | [Shaded] |    |    |    |    |    |      |    |    |      |    |          |    |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0    | 0  | 1  | 0    | 0  | 0        | 0  | 1  | 0  | 1  |

### USBHS\_HWGENERAL field descriptions

| Field             | Description  |
|-------------------|--|
| 31–11<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 10–9<br>SM        | Serial mode<br>Indicates presence of serial interface in controller configuration. Value is specific to controller configuration selected by manufacturer for this product.<br>00 No Serial Engine, always use parallel signaling. |
| 8–6<br>PHYM       | PHY Mode<br>Indicates interface to USB Phy used. Value is specific to controller configuration selected by manufacturer for this product.<br>010 Controller configured for ULPI interface.   |
| 5–4<br>PHYW       | PHY Width<br>Indicates width of data interface to USB Phy. This field is relevant for UTMI mode only and has value 00 for products with other Phy interfaces.<br>00 Value for non-UTMI interface configurations.                   |
| 3–0<br>Reserved   | Reserved<br>This field is reserved.<br>These read-only bits reflect other configuration parameters for this controller configuration.  |

### 51.3.3 Host Hardware Parameters Register (USBHS\_HWHOST)

The HWHOST register provides host hardware parameters for this implementation of the module.

Address: 4003\_4000h base + 8h offset = 4003\_4008h

|       |          |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
|-------|----------|----|----|----|----|----|----|----|-------|----|----|----|-------|----|----|----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23    | 22 | 21 | 20 | 19    | 18 | 17 | 16 |
| R     | TTPER    |    |    |    |    |    |    |    | TTASY |    |    |    |       |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
| Reset | 0        | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0     | 0  | 1  | 0  |
| Bit   | 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7     | 6  | 5  | 4  | 3     | 2  | 1  | 0  |
| R     | 0        |    |    |    |    |    |    |    |       |    |    |    | NPORT |    | HC |    |
| W     | [Shaded] |    |    |    |    |    |    |    |       |    |    |    |       |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0     | 0  | 0  | 1  |

**USBHS\_HWHOST field descriptions**

| Field            | Description  |
|------------------|--|
| 31–24<br>TTPER   | Transaction translator periodic contexts.<br>The number of supported transaction translator periodic contexts. Always reads as 0x10 (16 contexts supported). |
| 23–16<br>TTASY   | Transaction translator contexts.<br>The number of transaction translator contexts. Always reads as 0x02.   |
| 15–4<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3–1<br>NPORT     | Number of Ports<br>Always 0, indicating the number of ports available (NPORT + 1) for this host implementation.  |
| 0<br>HC          | Host Capable<br>Always reads as 0b1, indicating the module is host capable.  |

**51.3.4 Device Hardware Parameters Register (USBHS\_HWDEVICE)**

Provides device hardware parameters for this implementation of the USBHS module.

Address: 4003\_4000h base + Ch offset = 4003\_400Ch

|       |              |    |    |    |    |    |    |    |              |    |    |    |    |    |              |    |
|-------|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|--------------|----|
| Bit   | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17           | 16 |
| R     | 0            |    |    |    |    |    |    |    |              |    |    |    |    |    |              |    |
| W     | [Greyed out] |    |    |    |    |    |    |    |              |    |    |    |    |    |              |    |
| Reset | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0            | 0  | 0  | 0  | 0  | 0  | 0            | 0  |
| Bit   | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6  | 5  | 4  | 3  | 2  | 1            | 0  |

### USBHS\_HWDEVICE field descriptions (continued)

| Field   | Description   |
|---------|---|
| 0<br>DC | Device Capable<br>Always reads as 0b1, indicating the USBHS module is device capable. |

### 51.3.5 Transmit Buffer Hardware Parameters Register (USBHS\_HWTXBUF)

The HWTXBUF register provides the transmit buffer parameters for this implementation of the module.

Address: 4003\_4000h base + 10h offset = 4003\_4010h

|       |          |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
|-------|----------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R     | TXLC     | 0  |    |    |    |    |    |    | TXCHANADD |    |    |    |    |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
| Reset | 1        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  | 0  | 0  | 0  | 1  | 1  | 1  |

| R     | TXADD    |    |    |    |    |    |    |    | TXBURST   |    |    |    |    |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 1  | 0  | 0  | 1  | 0         | 0  | 0  | 0  | 1  | 0  | 0  | 0  |

### USBHS\_HWTXBUF field descriptions

| Field              | Description  |
|--------------------|--|
| 31<br>TXLC         | Transmit local Context Registers<br>Indicates how the device transmit context registers implement. Always set.<br>0 Store device transmit contexts in the TX FIFO<br>1 Store device transmit contexts in a register file |
| 30–24<br>Reserved  | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 23–16<br>TXCHANADD | Transmit Channel Address<br>The number of address bits required to address one channel's worth of TX data. Always 0x7.   |
| 15–8<br>TXADD      | Transmit Address.<br>The number of address bits for the entire TX buffer. Always 0x9.  |
| 7–0<br>TXBURST     | Transmit Burst.<br>Indicates the number of data beats in a burst for transmit DMA data transfers. Always 0x8.  |

### 51.3.6 Receive Buffer Hardware Parameters Register (USBHS\_HWRXBUF)

The HWRXBUF register provide the receive buffer parameters for this implementation of the module.

Address: 4003\_4000h base + 14h offset = 4003\_4014h

|       |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |         |   |   |   |   |   |   |   |   |   |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---------|---|---|---|---|---|---|---|---|---|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9       | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | 0        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RXADD |    |    |    |    |    | RXBURST |   |   |   |   |   |   |   |   |   |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |         |   |   |   |   |   |   |   |   |   |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 1  | 0  | 0       | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

#### USBHS\_HWRXBUF field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.                   |
| 15–8<br>RXADD     | Receive Address.<br>The number of address bits for the entire RX buffer. Always reads as 0x08.                        |
| 7–0<br>RXBURST    | Receive Burst.<br>Indicates the number of data beats in a burst for receive DMA data transfers. Always reads as 0x08. |

### 51.3.7 General Purpose Timer n Load Register (USBHS\_GPTIMERnLD)

The GPTIMERnLD register contains the timer duration or load value.

Address: 4003\_4000h base + 80h offset + (8d × i), where i=0d to 1d

|       |          |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
|-------|----------|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|--|--|--|--|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23    | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |  |  |  |  |
| R     | 0        |    |    |    |    |    |    |    | GPTLD |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| W     | [Shaded] |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |  |  |

#### USBHS\_GPTIMERnLD field descriptions

| Field             | Description                         |
|-------------------|-------------------------------------|
| 31–24<br>Reserved | Reserved<br>This field is reserved. |

Table continues on the next page...

**USBHS\_GPTIMERnLD field descriptions (continued)**

| Field         | Description  |
|---------------|--|
|               | This read-only field is reserved and always has the value 0.   |
| 23–0<br>GPTLD | Specifies the value to be loaded into the countdown timer on a reset. The value in this register represents the time in microseconds minus 1 for the timer duration. For example, for a one millisecond timer, load $1000 - 1 = 999$ (0x00_03E7).<br><br><b>NOTE:</b> Maximum value is 0xFF_FFFF or 16.777215 seconds. |

**51.3.8 General Purpose Timer n Control Register (USBHS\_GPTIMERnCTL)**

The GPTIMERnCTL register controls the various functions of the general purpose timers.

Address: 4003\_4000h base + 84h offset + (8d × i), where i=0d to 1d

**USBHS\_GPTIMERnCTL field descriptions**

| Field     | Description   |
|-----------|---|
| 31<br>RUN | Timer Run<br><br>Enables the general purpose timer. Setting or clearing this bit does not have an effect on the GPTCNT field. |

*Table continues on the next page...*

**USBHS\_GPTIMERnCTL field descriptions (continued)**

| Field             | Description  |
|-------------------|--|
|                   | 0 Timer stop<br>1 Timer run  |
| 30<br>RST         | Timer Reset<br>Setting this bit reloads GPTCNT with the value in GPTIMERnLD[GPTLD].<br>0 No action<br>1 Load counter value   |
| 29–25<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 24<br>MODE        | Timer Mode<br>Selects between a single timer countdown and a looped countdown. In one-shot mode, the timer counts down to zero, generates an interrupt, and stops until the counter is reset by software. In repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter and begins another countdown.<br>0 One shot<br>1 Repeat |
| 23–0<br>GPTCNT    | Timer Count<br>Indicates the current value of the running timer.   |

**51.3.9 System Bus Interface Configuration Register (USBHS\_USB\_SBUSCFG)**

The System Bus Interface Configuration (USB\_SBUSCFG) register contains the control for the system bus interface.

Address: 4003\_4000h base + 90h offset = 4003\_4090h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17        | 16 |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  |
| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1         | 0  |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    | BURSTMODE |    |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0         | 0  |

### USBHS\_USB\_SBUSCFG field descriptions

| Field            | Description  |
|------------------|--|
| 31–3<br>Reserved | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 2–0<br>BURSTMODE | <p>Burst mode</p> <p>Selects the options for the burst signal of the Master Interface.</p> <p>In all cases where the unspecified length burst is allowed, single accesses may also occur; this is mostly true when the transaction is not 32-bit aligned. Two consecutive single accesses should not happen.</p> <p>When an INCRx burst size is selected and the transfer is not multiple of the INCRx burst, the burst is decomposed in the different ways. With BURSTMODE[2] = 1, the smaller bursts is unspecified length. with BURSTMODE[2] = 0, the smaller bursts are smaller INCRx or singles. For example, if it were required at a given time to transfer 22 words of information, for the following values of BURSTMODE the master sequences are:</p> <p>101 INCR4 + INCR4 + INCR4 + INCR4 + INCR4 + INCR unspec. length.<br/>           110 INCR8 + INCR8 + INCR4 + INCR unspec. length.<br/>           111 INCR16 + INCR4 + INCR unspec. length.<br/>           001 INCR4 + INCR4 + INCR4 + INCR4 + INCR4 + SINGLE + SINGLE.<br/>           010 INCR8 + INCR8 + INCR4 + SINGLE + SINGLE.<br/>           011 INCR16 + INCR4 + SINGLE + SINGLE.</p> <p>When this field is different from zero, the values in the TXBURST/RXBURST bitfields in the USB_BURSTSIZE register are ignored by the controller.</p> <p>Internally the BURSTMODE is set to the value of the INCRx burst. Since this has a direct relation with the burst sizes you must be careful with AHB burst selected. Although the TXBURST/RXBURST are bypassed, this register can be written/read with no effect while the BURSTMODE field is non-zero.</p> <p><b>NOTE:</b> Setting the BURSTMODE value to 000 might cause bus allocation during BULK or ISO transfers.</p> <p><b>NOTE:</b> Changing this BURSTMODE field while a transaction is in progress yields undefined results. One possible way to prevent undefined results is to clear the Run/Stop (RS) bit in the USB_USBCMD register, after the HCHALTED is detected in USB_USBSTS.</p> <p>000 INCR burst of unspecified length<br/>           001 INCR4, non-multiple transfers of INCR4 is decomposed into singles.<br/>           010 INCR8, non-multiple transfers of INCR8, is decomposed into INCR4 or singles.<br/>           011 INCR16, non-multiple transfers of INCR16, is decomposed into INCR8, INCR4 or singles.<br/>           100 Reserved, do not use.<br/>           101 INCR4, non-multiple transfers of INCR4 is decomposed into smaller unspecified length bursts.<br/>           110 INCR8, non-multiple transfers of INCR8 is decomposed into smaller unspecified length bursts.<br/>           111 INCR16, non-multiple transfers of INCR16 is decomposed into smaller unspecified length bursts.</p> |

### 51.3.10 Host Controller Interface Version and Capability Registers Length Register (USBHS\_HCIVERSION)

Contains the CAPLENGTH field used as an offset to add to the register base address to find the beginning of the operational register space, the location of the USBCMD register. Also contains a BCD encoding of the EHCI revision number supported by this OTG controller. The most-significant byte of the HCIVERSION field represents a major revision; the least-significant byte is the minor revision.

Address: 4003\_4000h base + 100h offset = 4003\_4100h

|       |            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |           |   |   |   |   |   |   |   |   |   |
|-------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|-----------|---|---|---|---|---|---|---|---|---|
| Bit   | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9         | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | HCIVERSION |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0        |    |    |    |    |    | CAPLENGTH |   |   |   |   |   |   |   |   |   |
| W     | [Shaded]   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | [Shaded] |    |    |    |    |    | [Shaded]  |   |   |   |   |   |   |   |   |   |
| Reset | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0        | 0  | 0  | 0  | 0  | 0  | 0         | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |

#### USBHS\_HCIVERSION field descriptions

| Field               | Description   |
|---------------------|---|
| 31–16<br>HCIVERSION | EHCI revision number<br>Value is reads as 0x0100, indicating version 1.0.                           |
| 15–8<br>Reserved    | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 7–0<br>CAPLENGTH    | Capability registers length<br>Always reads as 0x40.  |

### 51.3.11 Host Controller Structural Parameters Register (USBHS\_HCSPARAMS)

This register contains structural parameters such as the number of downstream ports.

Address: 4003\_4000h base + 104h offset = 4003\_4104h

|       |            |    |    |    |       |    |    |    |       |    |     |         |    |    |    |    |
|-------|------------|----|----|----|-------|----|----|----|-------|----|-----|---------|----|----|----|----|
| Bit   | 31         | 30 | 29 | 28 | 27    | 26 | 25 | 24 | 23    | 22 | 21  | 20      | 19 | 18 | 17 | 16 |
| R     | 0          |    |    |    | N_TT  |    |    |    | N_PTT |    |     |         | 0  |    | PI |    |
| W     | [Reserved] |    |    |    |       |    |    |    |       |    |     |         |    |    |    |    |
| Reset | 0          | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0     | 0  | 0   | 0       | 0  | 0  | 0  | 1  |

| 2<br>ASP      | <p>Asynchronous Schedule Park capability</p> <p>Indicates if the host controller supports the park feature for high-speed queue heads in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using the asynchronous schedule park mode enable and asynchronous schedule park mode count fields in the USBCMD register. This bit always reads as 0b1.</p> <p>0 Park not supported.<br/>1 Park supported.</p> |
| 1<br>PFL      | <p>Programmable Frame List flag</p> <p>Indicates that system software can specify and use a frame list length less than 1024 elements. This bit always reads as 0b1.</p> <p>1 Frame list size is configured via the USBCMD register frame list size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.</p>  |
| 0<br>ADC      | <p>64-bit addressing capability.</p> <p>This bit always reads as 0b0, indicating 64-bit addressing is not supported.</p> <p>0 Data structures use 32-bit address memory pointers</p>   |

**51.3.13 Device Controller Interface Version (USBHS\_DCIVERSION)**

Not defined in the EHCI specification. DCIVERSION is a two-byte register containing a BCD encoding of the device controller interface. The most-significant byte of the register represents a major revision and the least-significant byte is the minor revision.

Address: 4003\_4000h base + 122h offset = 4003\_4122h

**USBHS\_DCIVERSION field descriptions**

**USBHS\_USBCMD field descriptions (continued)**

| Field          | Description  |
|----------------|--|
|                | machine is in a hazard region where adding a dTD to a primed endpoint may go unrecognized. More information appears in section “Executing a Transfer Descriptor.”  |
| 13<br>SUTW     | Setup TripWire<br><br>This is a non-EHCI bit. Used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by driver software without being corrupted. If the setup lockout mode is off (USBMODE[SLOM] = 1) then a hazard exists when new setup data arrives, and the software copies setup from the QH for a previous setup packet. This bit is set and cleared by software and is cleared by hardware when a hazard exists. More information appears in section “Control Endpoint Operation.”   |
| 12<br>Reserved | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 11<br>ASPE     | Asynchronous Schedule Park mode Enable<br><br>Software uses this bit to enable or disable park mode.<br><br>0 Park mode disabled<br>1 Park mode enabled  |
| 10<br>Reserved | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 9–8<br>ASP     | Asynchronous Schedule Park mode count<br><br>Contains a count of the successive transactions the host controller can execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0b1 to 0b11. Software must not write a zero to this field when ASPE is set as this results in undefined behavior.  |
| 7<br>Reserved  | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 6<br>IAA       | Interrupt on Async Advance doorbell<br><br>Used as a doorbell by software to tell controller to issue an interrupt the next time it advances the asynchronous schedule. Software must write a 1 to this bit to ring the doorbell.<br><br>When controller has evicted all appropriate cached schedule states, it sets USBSTS[AAI] register. If the USBINTR[AAE] bit is set, the host controller asserts an interrupt at the next interrupt threshold.<br><br>The controller clears this bit after it has set the USBSTS[AAI] bit. Software must not write a 1 to this bit when the asynchronous schedule is inactive. Doing so yields undefined results. This bit used only in host mode.<br><br>Writing a 1 to this bit when the USBHS module is in device mode has undefined results. |
| 5<br>ASE       | Asynchronous Schedule Enable<br><br>Controls whether the controller skips processing the asynchronous schedule. Only used in host mode.<br><br>0 Do not process asynchronous schedule.<br>1 Use the ASYNCLISTADDR register to access asynchronous schedule.  |
| 4<br>PSE       | Periodic Schedule Enable<br><br>Controls whether the controller skips processing periodic schedule. Used only in host mode.  |

*Table continues on the next page...*

**USBHS\_USBCMD field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
|                   | <p>0 Do not process periodic schedule.</p> <p>1 Use the PERIODICLISTBASE register to access the periodic schedule.</p>  |
| <p>3–2<br/>FS</p> | <p>Frame list Size</p> <p>With bit 15, these bits make the FS[2:0] field, which specifies the frame list size controlling which bits in the frame index register must be used for the frame list current index. Used only in host mode.</p> <p><b>NOTE:</b> Values below 256 elements are not defined in the EHCI specification.</p> <p>00 When FS2 = 0, the size is 1024 elements (4096 bytes). When FS2 = 1, the size is 64 elements (256 bytes).</p> <p>01 When FS2 = 0, the size is 512 elements (2048 bytes). When FS2 = 1, the size is 32 elements (128 bytes).</p> <p>10 When FS2 = 0, the size is 256 elements (1024 bytes). When FS2 = 1, the size is 16 elements (64 bytes).</p> <p>11 When FS2 = 0, the size is 128 elements (512 bytes). When FS2 = 1, the size is 8 elements (32 bytes).</p>   |
| <p>1<br/>RST</p>  | <p>Controller Reset</p> <p>Software uses this bit to reset controller. Controller clears this bit when reset process completes. Clearing this register does not allow software to terminate the reset process early.</p> <p>Host mode:</p> <p>When software sets this bit, the controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction in progress on the USB immediately terminates. A USB reset is not driven on downstream ports. Software must not set this bit when the USBSTS[HCH] bit is cleared. Attempting to reset an actively running host controller results in undefined behavior.</p> <p>Device mode:</p> <p>When software sets this bit, the controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Setting this bit with the device in the attached state is not recommended because it has an undefined effect on an attached host. To ensure the device is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed and the USBCMD[RS] bit must be cleared.</p> |
| <p>0<br/>RS</p>   | <p>Run/Stop</p> <p>Host mode:</p> <p>When set, the controller proceeds with the execution of the schedule. The controller continues execution as long as this bit is set. When this bit is cleared, the controller completes the current transaction on the USB and then halts. The USBSTS[HCH] bit indicates when the host controller finishes the transaction and enters the stopped state. Software must not set this bit unless controller is in halted state (USBSTS[HCH] = 1).</p> <p>Device mode:</p> <p>Setting this bit causes the controller to enable a pull-up on DP and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up becomes disabled upon transitioning into high-speed mode. Software must use this bit to prevent an attach event before the USBHS controller has properly initialized. Clearing this bit causes a detach event.</p>  |

### 51.3.16 USB Status Register (USBHS\_USBSTS)

This register indicates various states of each module and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus. Software clears certain bits in this register by writing a 1 to them.

Address: 4003\_4000h base + 144h offset = 4003\_4144h

The controller sets this bit after it stops executing because of the USBCMD[RS] bit being cleared, by software or the host controller hardware (for example, internal error). Used only in host mode.</p>  |

*Table continues on the next page...*

**USBHS\_USBSTS field descriptions (continued)**

| Field          | Description  |
|----------------|--|
|                | 0 Running<br>1 Halted  |
| 11<br>Reserved | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 10<br>ULPII    | ULPI Interrupt<br><br>This bit will be set to value '1b1' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller is configured to support ULPI mode.  |
| 9<br>Reserved  | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 8<br>SLI       | Device-controller suspend<br><br>Non-EHCI bit. When a device controller enters a suspend state from an active state, this bit is set. The device controller clears the bit upon exiting from a suspend state. Used only by the device controller.<br><br>0 Active<br>1 Suspended   |
| 7<br>SRI       | SOF Received<br><br>This is a non-EHCI status bit. Software writes a 1 to this bit to clear it.<br><br>Host mode:<br><br>In host mode, this bit is set every 125 ms, provided PHY clock is present and running (for example, the port is NOT suspended) and can be used by the host-controller driver as a time base.<br><br>Device mode:<br><br>When controller detects a start of (micro) frame, bit is set. When a SOF is extremely late, controller automatically sets this bit to indicate an SOF was expected. Therefore, this bit is set roughly every 1 ms in device FS mode and every 125 us in HS mode, and it is synchronized to the actual SOF received. Because the controller is initialized to FS before connect, this bit is set at an interval of 1 ms during the prelude to the connect and chirp. |
| 6<br>URI       | USB Reset received<br><br>A non-EHCI bit. When the controller detects a USB reset and enters the default state, this bit is set. Software can write a 1 to this bit to clear it. Used only by in device mode.<br><br>0 No reset received<br>1 Reset received   |
| 5<br>AAI       | Interrupt on Async Advance<br><br>By setting the USBCMD[IAA] bit, system software can force the controller to issue an interrupt the next time the controller advances the asynchronous schedule. This status bit indicates the assertion of that interrupt source. Used only by the host mode.<br><br>0 No async advance interrupt<br>1 Async advance interrupt   |
| 4<br>SEI       | System Error<br><br>Set when an error is detected on the system bus. If the system error enable bit (USBINTR[SEE]) is set, interrupt generates. The interrupt and status bits remain set until cleared by writing a 1 to this bit.   |

*Table continues on the next page...*

### USBHS\_USBSTS field descriptions (continued)

| Field    | Description  |
|----------|--|
|          | <p>Additionally, when in host mode, the USBCMD[RS] bit is cleared, effectively disabling controller. An interrupt generates for the USBHS controller in device mode, but no other action is taken.</p> <p>0 Normal operation<br/>1 Error</p>   |
| 3<br>FRI | <p>Frame-list Rollover</p> <p>Controller sets this bit when the frame list index (FRINDEX) rolls over from its maximum value to 0. The exact value the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in the USBCMD[FS] field) is 1024, the frame index register rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the controller sets this bit each time FRINDEX[12] toggles. Used only in the host mode.</p>   |
| 2<br>PCI | <p>Port Change detect</p> <p>This bit is not EHCI compatible.</p> <p>Host mode:</p> <p>Controller sets this bit when a connect status occurs on any port, a port enable/disable change occurs, an over-current change occurs, or the force port resume (PORTSCn[FPR]) bit is set as the result of a J-K transition on the suspended port.</p> <p>Device mode:</p> <p>The controller sets this bit when it enters the full- or high-speed operational state. When it exits the full- or high-speed operation states due to reset or suspend events, the notification mechanisms are URI and SLI bits respectively. The device controller detects resume signaling only.</p> |
| 1<br>UEI | <p>USB Error Interrupt</p> <p>When completion of USB transaction results in error condition, the controller sets this bit. If the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set, this bit is set along with the USBINT bit. See Section 4.15.1 in the EHCI specification for a complete list of host error interrupt conditions. See Table 24-62 for more information on device error matrix.</p> <p>0 No error<br/>1 Error detected</p>   |
| 0<br>UI  | <p>USB Interrupt (USBINT)</p> <p>This bit is set by the controller when the cause of an interrupt is a completion of a USB transaction where the TD has an interrupt on complete (IOC) bit set. This bit is also set by the controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>   |

### 51.3.17 USB Interrupt Enable Register (USBHS\_USBINTR)

The interrupts to software are enabled with this register. An interrupt generates when a bit is set and the corresponding interrupt is active. The USB status register (USBSTS) continues to show interrupt sources (even if the USBINTR register disables them), allowing polling of interrupt events by the software.

Address: 4003\_4000h base + 148h offset = 4003\_4148h

### 51.3.18 Frame Index Register (USBHS\_FRINDEX)

In host mode, the controller uses this register to index the periodic frame list. The register updates every 125 microseconds (once each microframe). Bits [N–3] select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the USBCMD[FS] field.

Only perform 32-bit accesses to this register. Byte writes produce undefined results. This register cannot be written unless the USBHS controller is in halted state as the USBSTS[HCH] bit indicates. A write to this register while the USBSTS[RS] bit is set produces undefined results. Writes to this register also affect the SOF value.

In device mode, this register is read-only, and the USBHS controller updates the FRINDEX[13–3] bits from the frame number the SOF marker indicates. When the USB bus receives a SOF, FRINDEX[13–3] checks against the SOF marker. If FRINDEX[13–3] is different from the SOF marker, FRINDEX[13–3] is set to the SOF value and FRINDEX[2–0] is cleared (SOF for 1 ms frame). If FRINDEX[13–3] equals the SOF value, FRINDEX[2–0] is incremented (SOF for 125 microsec microframe.)

Address: 4003\_4000h base + 14Ch offset = 4003\_414Ch

### 51.3.19 Periodic Frame List Base Address Register (USBHS\_PERIODICLISTBASE)

This register contains the beginning address of the periodic frame list in the system memory. The host controller driver loads this register prior to starting the schedule execution by the controller. The memory structure referenced by this physical memory pointer assumes to be 4-Kbyte aligned. The contents combine with the FRINDEX register to enable the controller to step through the periodic frame list in sequence.

**The host and device mode functions share this register. In host mode, it is the PERIODICLISTBASE register; in device mode, it is the DEVICEADDR register.** See section “Device Address Register (DEVICEADDR),” for more information.

Address: 4003\_4000h base + 154h offset = 4003\_4154h

### 51.3.20 Device Address Register (USBHS\_DEVICEADDR)

This register is not defined in the EHCI specification. For device mode, the upper seven bits of this register represent the device address. After any controller or USB reset, the device address is set to the default address (0). The default address matches all incoming addresses. Software reprograms the address after receiving a SET\_ADDRESS descriptor.

**The host and device mode functions share this register. In device mode, it is the DEVICEADDR register; in host mode, it is the PERIODICLISTBASE register. See section “Periodic Frame List Base Address Register (PERIODICLISTBASE),” for more information.**

| Field            | Description  |
|------------------|--|
|                  | 0 Writes to USBADR are instantaneous.<br>1 When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR is loaded from the holding register. |
| 23–0<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

**51.3.21 Current Asynchronous List Address Register (USBHS\_ASYNCCLISTADDR)**

The ASYNCLISTADDR register contains the address of the next asynchronous queue head to executed by the host.

**The host and device mode functions share this register. In host mode, it is the ASYNCLISTADDR register; in device mode, it is the EPLISTADDR register.** See section “Endpoint List Address Register (EPLISTADDR),” for more information.

Address: 4003\_4000h base + 158h offset = 4003\_4158h

**USBHS\_ASYNCCLISTADDR field descriptions**

| Field           | Description   |
|-----------------|---|
| 31–5<br>ASYBASE | Link pointer low (LPL)<br>These bits correspond to memory address signal [31:5]. This field may only reference a queue head (QH). Used only in host mode. |
| 4–0<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 51.3.22 Endpoint List Address Register (USBHS\_EPLISTADDR)

This register is not defined in the EHCI specification. For device mode, this register contains the address of the endpoint list top in system memory. The memory structure referenced by this physical memory pointer assumes to be 64-bytes. The queue head is actually a 48-byte structure, but must be aligned on 64-byte boundary. However, the EPBASE field has a granularity of 2 Kbytes; in practice, the queue head should be 2-Kbyte aligned.

**The host and device mode functions share this register. In device mode, it is the EPLISTADDR register; in host mode, it is the ASYNCLISTADDR register. See section “Current Asynchronous List Address Register (ASYNCLISTADDR),” for more information.**

Address: 4003\_4000h base + 158h offset = 4003\_4158h

#### USBHS\_EPLISTADDR field descriptions

| Field            | Description  |
|------------------|--|
| 31–11<br>EPBASE  | Endpoint list address<br>Correspond to memory address signals [31:11] References a list of up to 32 queue heads (i.e. one queue head per endpoint and direction). Address of the top of the endpoint list. |

| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | TXPBURST |    |    |    |    |    | RXPBURST |   |   |   |   |   |   |   |   |   |
| W     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0        |    |    |    |    |    | 0        |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0        | 0  | 0  | 0  | 1  | 0  | 0        | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

### USBHS\_BURSTSIZE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 15–8<br>TXPBURST  | Programable TX Burst length<br>Represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus. Must not be set to greater than 16.<br>If the BURSTSIZE field of register SBUSCFG is non-zero, the TXPBURST field returns the value of the INCRx length.               |
| 7–0<br>RXPBURST   | Programable RX Burst length<br>This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory. Must not be set to greater than 16.<br>If the BURSTSIZE field of register SBUSCFG is non-zero, the RXPBURST field returns the value of the INCRx length. |

### 51.3.25 Transmit FIFO Tuning Control Register (USBHS\_TXFILLTUNING)

This register is not defined in the EHCI specification. The TXFILLTUNING register controls performance tuning associated with how the module posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation takes in the target system.

Definitions:

$T_0$  = Standard packet overhead

$T_1$  = Time to send data payload

$T_s$  = Total packet flight time (send-only) packet ( $T_s = T_0 + T_1$ )

$T_{ff}$  Time to fetch packet into TX FIFO up to specified level

$T_p$  Total packet time (fetch and send) packet ( $T_p = T_{ff} + T_s$ )

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, the host controller checks to ensure  $T_p$  remains before the end of the (micro)frame. If so, it pre-fills the TX FIFO. If at anytime during the pre-fill operation the time remaining the (micro)frame is less than  $T_s$ , packet attempt ceases and tries at a later time. Although this is not an error condition and the module eventually recovers, a mark is made in the scheduler health counter to mark the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic beginning after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and should be minimized (not necessarily eliminated). The TSCHEALTH ( $T_{ff}$ ) parameter described below can minimize back-offs.

Address: 4003\_4000h base + 164h offset = 4003\_4164h

|       |    |    |    |             |    |    |    |    |             |         |    |    |    |    |    |    |

| R     | 0  |    |    | TXSCHHEALTH |    |    |    |    | 0           | TXSCHOH |    |    |    |    |    |    |
| W     | 0  |    |    | 0           |    |    |    |    | 0           | 0       |    |    |    |    |    |    |
| Reset | 0  | 0  | 0  | 0           | 0  | 0  | 0  | 0  | 0           | 0       | 0  | 0  | 0  | 0  | 0  | 0  |

**USBHS\_TXFILLTUNING field descriptions**

| Field                | Description  |
|----------------------|--|
| 31–22<br>Reserved    | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 21–16<br>TXFIFOTHRES | FIFO burst Threshold<br>FIFO burst threshold. Controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. Systems with unpredictable latency and/or insufficient bandwidth can use a higher value where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can replenish from system memory.<br><br>This value is ignored if the USBMODE[SDIS] bit is set. When the USBMODE[SDIS] bit is set, the host controller behaves as if TXFIFOTHRES is set to its maximum value.   |
| 15–13<br>Reserved    | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 12–8<br>TXSCHHEALTH  | Scheduler Health counter<br>These bits increment when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next SOF.<br><br>This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register clears the counter and this counter stops counting after reaching the maximum of 31.   |
| 7<br>Reserved        | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 6–0<br>TXSCHOH       | Scheduler Overhead<br>These bits add an additional fixed offset to the schedule time estimator described as $T_{ff}$ . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH field to less than 10 per second in a highly utilized bus. Choosing a value too high for this register is not desired as it can needlessly reduce USB utilization.<br><br>The time unit represented in this register is 1.267 ms when a device connects in high-speed mode.<br>The time unit represented in this register is 6.333 ms when a device connects in low-/full-speed mode.<br><br>For most applications, TXSCHOH can be set to 4 or less. A good value to begin with is:<br>$(TXFIFOTHRES \times BURSTSIZE \times 4) / (40 \times \text{TimeUnit})$<br>Always rounded to the next higher integer. TimeUnit is 1.267 or 6.333 as noted earlier in this description. For example, if TXFIFOTHRES is 5 and BURSTSIZE is 8, set TXSCHOH to $5 \times (8 \times 4) / (40 \times 1.267)$ equals 4 for a high-speed link. If this value of TXSCHOH results in a TXSCHHEALTH count of 0 per second, low the value by 1 if optimizing performance is desired. If TXSCHHEALTH exceeds 10 per second, raise the value by 1.<br><br>If streaming mode is disabled via the USBMODE register, treat TXFIFOTHRES as the maximum value for purposes of the TXSCHOH calculation. |

### 51.3.26 ULPI Register Access (USBHS\_ULPI\_VIEWPORT)

The register provides indirect access to the ULPI PHY register set. Although the controller modules perform access to the ULPI PHY register set, there may be circumstances where software may need direct access.

#### NOTE

Be advised that writes to the ULPI through the ULPI viewport can substantially harm standard USB operations. Currently no usage model has been defined where software should need to execute writes directly to the ULPI. Executing read operations through the ULPI viewport should have no harmful side effects to standard USB operations. Also, if the ULPI interface is not enabled, this register is always read cleared.

There are two operations that can be performed with the ULPI viewport, wake-up and read/write operations. The wake-up operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wake-up operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode. The ULPI state can be determined by reading the sync state bit (ULPI\_SS). If this bit is set, then the ULPI interface is running in normal operating mode and can accept read/write operations. If ULPI\_SS is cleared, then read/write operations are not executed. Undefined behavior results if a read or write operation is performed when ULPI\_SS is cleared. To execute a wake-up operation, write all 32-bits of the ULPI VIEWPORT where ULPI\_PORT is constructed appropriately and the ULPI\_WU bit is set and the ULPI\_RUN bit is cleared. Poll the ULPI VIEWPORT until ULPI\_WU is cleared for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI VIEWPORT where ULPI\_DATWR, ULPI\_ADDR, ULPI\_PORT, ULPI\_RW are constructed appropriately and the ULPI\_RUN bit is set. Poll the ULPI VIEWPORT until ULPI\_RUN is cleared for the operation to complete. For read operations, ULPI\_DATRD is valid after ULPI\_RUN is cleared.

The polling method above can be replaced with interrupts using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wake-up or read/write operation completes, the ULPI interrupt is set.

Address: 4003\_4000h base + 170h offset = 4003\_4170h

**USBHS\_ULPI\_VIEWPORT field descriptions**

| Field          | Description   |
|----------------|---|
| 31<br>ULPI_WU  | <p>ULPI Wake-Up</p> <p>Setting this bit begins the wake-up operation. This bit automatically clears after the wake-up is complete. After this bit is set, it can not be cleared by software.</p> <p><b>NOTE:</b> The driver must never execute a wake-up and a read/write operation at the same time.</p> |
| 30<br>ULPI_RUN | <p>ULPI Run</p> <p>Setting this bit begins a read/write operation. This bit automatically clears after the read/write is complete. After this bit is set, it can not be cleared by software.</p> <p><b>NOTE:</b> The driver must never execute a wake-up and a read/write operation at the same time.</p> |
| 29<br>ULPI_RW  | <p>ULPI Read/Write</p> <p>Selects between running a read or write operation to the ULPI.</p> <p>0 Read<br/>1 Write</p>  |
| 28<br>Reserved | <p>Reserved</p> <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 27<br>ULPI_SS  | <p>ULPI Sync State</p> <p>Represents the state of the ULPI interface. Before reading this bit, the ULPI_PORT field should be set accordingly if used with the multi-port host. Otherwise, this field should always remain 0.</p>  |

### 51.3.30 Port Status and Control Registers (USBHS\_PORTSC1)

The USB module contains a single PORTSC register. This register only resets when power is initially applied or in response to a controller reset. Initial conditions of a port are:

- No device connected
- Port disabled

If the port has port power control, this state remains until software applies power to the port by setting port power to one.

For the USBHS module in device mode, the USBHS controller does not support power control. Port control in device mode is used only for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling, and allows software to place the PHY into low-power suspend mode and disable the PHY clock.

Address: 4003\_4000h base + 184h offset = 4003\_4184h

| 1         | 0   | Enable     |      |            |   |   |         |   |   |        |   |   |         |
| 1         | 1   | Suspend    |      |            |   |   |         |   |   |        |   |   |         |
| 6<br>FPR  | <p>Force Port Resume</p> <p>This bit is not-EHCI compatible.</p> <p>Host mode:</p> <p>Software sets this bit to drive resume signaling. The controller sets this bit if a J-to-K transition is detected while the port is in suspend state (PE = SUSP = 1), which in turn sets the USBSTS[PCI] bit. This bit automatically clears after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to clear this bit after the resume duration is timed in the driver.</p>  |            |      |            |   |   |         |   |   |        |   |   |         |

*Table continues on the next page...*

**USBHS\_PORTSC1 field descriptions (continued)**

| Field            | Description   |
|------------------|---|
|                  | <p>When the controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (full-speed K) is driven on the port as long as this bit remains set. This bit remains set until the port switches to the high-speed idle. Clearing this bit has no affect because the port controller times the resume operation to clear the bit the port control state switches to HS or FS idle.</p> <p>This bit is cleared if the PP bit is cleared in host mode.</p> <p>Device mode:</p> <p>If remote wakeup is enabled, after the device is in suspend for 5 ms or more, software can set this bit to drive resume signaling before clearing. The device controller sets this bit if a J-to-K transition is detected while port is in suspend state, which in turn sets the USBSTS[PCI] bit. The bit is cleared when the device returns to normal operation.</p> <p>0 No resume (K-state) detected/driven on port<br/>1 Resume detected/driven on port</p> |
| <p>5<br/>OCC</p> | <p>Over-Current Change</p> <p>Indicates a change to the OCA bit. Software clears this bit by writing a 1. For host mode, the user can provide over-current detection to the USBn_PWRFAULT signal for this condition. For device-only implementations, this bit must always be cleared.</p> <p>0 No over-current<br/>1 Over-current detect</p>   |
| <p>4<br/>OCA</p> | <p>Over-current active</p> <p>This bit automatically transitions from 1 to 0 when the over-current condition is removed. For host/OTG implementations, the user can provide over-current detection to the USBn_PWRFAULT signal for this condition. For device-only implementations, this bit must always be cleared.</p> <p>0 Port not in over-current condition<br/>1 Port currently in over-current condition</p>   |
| <p>3<br/>PEC</p> | <p>Port Enable/disable Change</p> <p>For the root hub, this bit gets set only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification).</p> <p>Software clears this by writing a 1 to it.</p> <p>In device mode, the device port is always enabled. (This bit is zero).</p> <p>This bit is cleared if the PP bit is cleared.</p> <p>0 No change<br/>1 Port disabled</p>  |
| <p>2<br/>PE</p>  | <p>Port Enabled/disabled</p> <p>Host mode:</p> <p>Ports can only be enabled by the controller as a part of the reset and enable sequence. Software cannot enable a port by setting this bit. A fault condition (disconnect event or other fault condition) or host software can disable ports. The bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host and bus events.</p> <p>When the port is disabled, downstream propagation of data is blocked except for reset. This field is cleared if the PP bit is cleared in host mode.</p>  |

### 51.3.31 On-the-Go Status and Control Register (USBHS\_OTGSC)

This register is not defined in the EHCI specification. The host controller implements one OTGSC register corresponding to port 0 of the host controller.

The OTGSC register has four sections:

OTG interrupt enables (read/write)

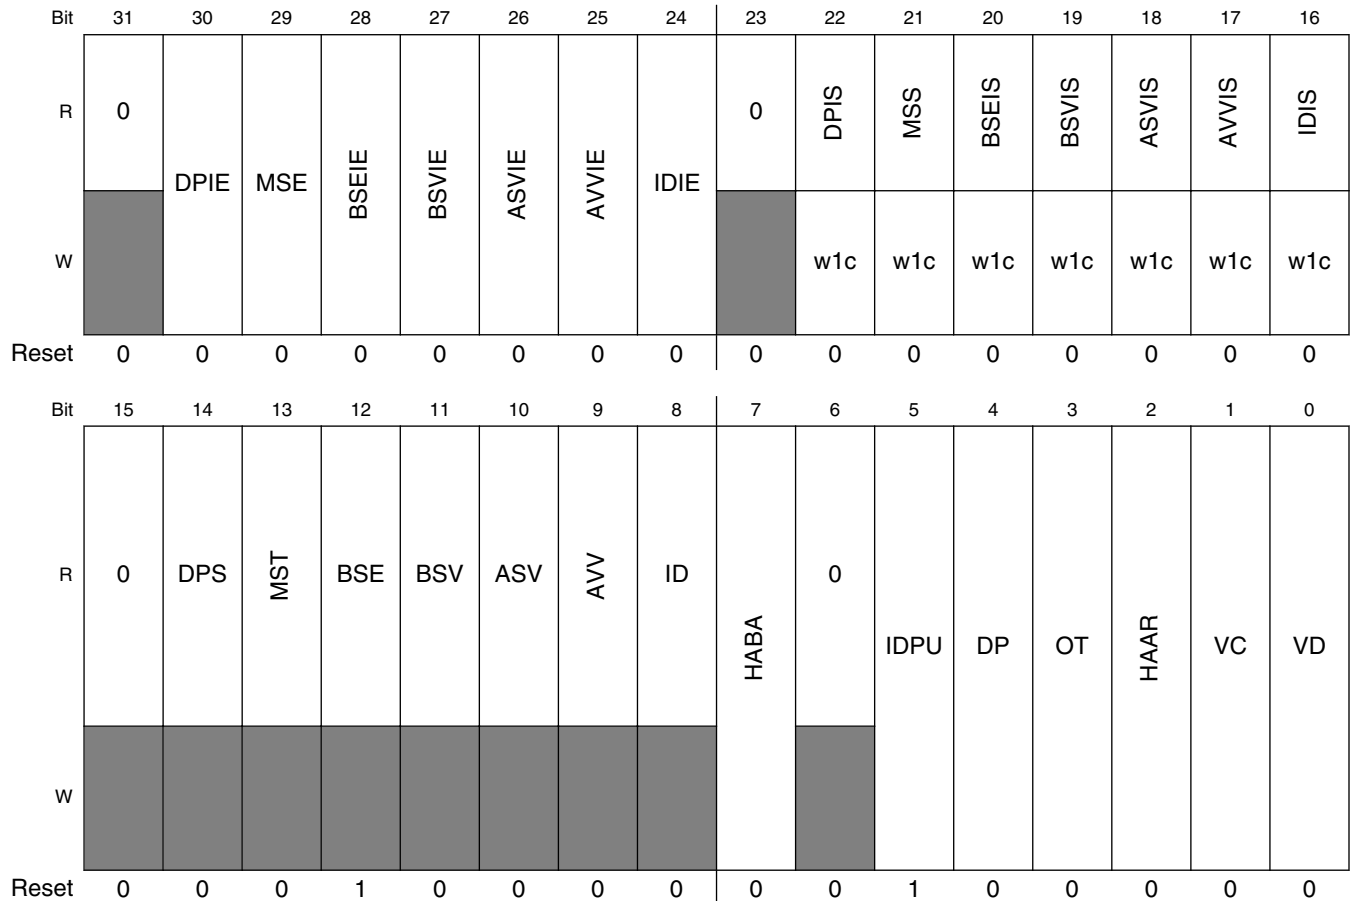

OTG interrupt status (read/write to clear)

OTG status inputs (read-only)

OTG controls (read/write)

The status inputs de-bounce using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status inputs or an OTG interrupt.

Address: 4003\_4000h base + 1A4h offset = 4003\_41A4h

### 51.3.33 Endpoint Setup Status Register (USBHS\_EPSETUPSR)

This register is not defined in the EHCI specification. This register contains the endpoint setup status and is used only in device mode.

Address: 4003\_4000h base + 1ACh offset = 4003\_41ACh

|       |          |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|-------------|----|----|----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19          | 18 | 17 | 16 |
| R     | 0        |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |    |             |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0           | 0  | 0  | 0  |

| R     | 0        |    |    |    |    |    |    |    |    |    |    |    | EPSETUPSTAT |    |    |    |
| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |    | w1c         |    |    |    |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0           | 0  | 0  | 0  |

#### USBHS\_EPSETUPSR field descriptions

| Field              | Description  |
|--------------------|--|
| 31–4<br>Reserved   | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3–0<br>EPSETUPSTAT | Setup Endpoint Status<br>For every setup transaction received, a corresponding bit in this field is set.<br>This register is used only in device mode.<br>Software must clear or acknowledge the setup transfer by writing a 1 to a respective bit after it has read the setup data from the queue head. The response to a setup packet, as in the order of operations and total response time, is crucial to limit bus time outs while the setup lockout mechanism engages. |

### 51.3.34 Endpoint Initialization Register (USBHS\_EPPRIME)

This register is not defined in the EHCI specification. This register is used to initialize endpoints and is used only in device mode.

Address: 4003\_4000h base + 1B0h offset = 4003\_41B0h

#### USBHS\_EPPRIME field descriptions

| Field             | Description   |
|-------------------|---|
| 31–20<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 19–16<br>PETB     | Prime Endpoint tTransmit Buffer<br>For each endpoint, a corresponding bit requests that a buffer be prepared for a transmit operation to respond to a USB IN/INTERRUPT transaction. Software must write a 1 to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when associated endpoint(s) is (are) successfully primed.<br><b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD retires, and the dQH updates. |
| 15–4<br>Reserved  | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3–0<br>PERB       | Prime Endpoint Receive Buffer<br>For each endpoint, a corresponding bit requests that a buffer be prepared for a receive operation to respond to a USB OUT transaction. Software must write a 1 to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when associated endpoint(s) is (are) successfully primed.<br><b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD retires, and the dQH updates.              |

### 51.3.35 Endpoint Flush Register (USBHS\_EPFLUSH)

This register is not defined in the EHCI specification. This register used only in device mode.

Address: 4003\_4000h base + 1B4h offset = 4003\_41B4h

#### USBHS\_EPFLUSH field descriptions

| Field             | Description   |
|-------------------|---|
| 31–20<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 19–16<br>FETB     | Flush Endpoint Transmit Buffer<br>Writing a 1 to a bit in this field causes the associated endpoint to clear any primed buffers. If a packet is in progress for an associated endpoint, that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful.                                   |
| 15–4<br>Reserved  | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3–0<br>FERB       | Flush Endpoint Receive Buffer<br>Writing a 1 to a bit in this field causes the associated endpoint to clear any primed buffers. If a packet is in progress for an associated endpoint, that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[3] corresponds to endpoint 3. |

### 51.3.36 Endpoint Status Register (USBHS\_EPSR)

This register is not defined in the EHCI specification. This register is only used in device mode.

Address: 4003\_4000h base + 1B8h offset = 4003\_41B8h

### USBHS\_EPISR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–20<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 19–16<br>ETBR     | Endpoint Transmit Buffer Ready<br>One bit for each endpoint indicates status of the respective endpoint buffer. The hardware sets this bit in response to receiving a command from a corresponding bit in the EPPRIME register. A constant delay exists between setting a bit in the EPPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the EPPRIME register. USB reset, USB DMA system, or EPFLUSH register clears the buffer ready. ETBR[3] (bit 19) corresponds to endpoint 3.<br><b>NOTE:</b> Hardware momentarily clears these bits during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. |
| 15–4<br>Reserved  | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 3–0<br>ERBR       | Endpoint Receive Buffer Ready<br>One bit for each endpoint indicates status of the respective endpoint buffer. The hardware sets this bit in response to receiving a command from a corresponding bit in the EPPRIME register. A constant delay exists between setting a bit in the EPPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the EPPRIME register. USB reset, USB DMA system, or EPFLUSH register clears the buffer ready. ERBR[3] (bit 19) corresponds to endpoint 3.<br><b>NOTE:</b> Hardware momentarily clears these bits during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.  |

### 51.3.37 Endpoint Complete Register (USBHS\_EPCOMPLETE)

This register is not defined in the EHCI specification. This register is used only in device mode.

Address: 4003\_4000h base + 1BCh offset = 4003\_41BCh

|       |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|------|---|---|---|
| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19   | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3    | 2 | 1 | 0 |
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    | ETCE |    |    |    | 0  |    |    |    |    |    |   |   |   |   |   |   | ERCE |   |   |   |
| W     | 0  |    |    |    |    |    |    |    |    |    |    |    | w1c  |    |    |    | 0  |    |    |    |    |    |   |   |   |   |   |   | w1c  |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0    | 0 | 0 | 0 |

### USBHS\_EPCOMPLETE field descriptions

| Field             | Description   |
|-------------------|---|
| 31–20<br>Reserved | Reserved<br>This field is reserved.<br>This read-only field is reserved and always has the value 0. |

Table continues on the next page...

### USBHS\_EPCOMPLETE field descriptions (continued)

| Field            | Description  |
|------------------|--|
| 19–16<br>ETCE    | Endpoint Transmit Complete Event<br><br>Each bit indicates a transmit event (IN/INTERRUPT) occurs and software must read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the transfer descriptor, this bit is set simultaneously with the USBINT. Writing a 1 clears the corresponding bit in this register. ETCE[3] (bit 19) corresponds to endpoint 3. |
| 15–4<br>Reserved | Reserved<br><br>This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3–0<br>ERCE      | Endpoint Receive Complete Event<br><br>Each bit indicates a received event (OUT/SETUP) occurs and software must read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the transfer descriptor, this bit is set simultaneously with the USBINT. Writing a 1 clears the corresponding bit in this register. ERCE[3] corresponds to endpoint 3.              |

### 51.3.38 Endpoint Control Register 0 (USBHS\_EPCR0)

This register is not defined in the EHCI specification. Every device implements endpoint 0 as a control endpoint.

Address: 4003\_4000h base + 1C0h offset = 4003\_41C0h

|       |          |    |    |    |    |    |    |    |     |    |    |    |    |     |    |    |     |
|-------|----------|----|----|----|----|----|----|----|-----|----|----|----|----|-----|----|----|-----|
| Bit   | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22 | 21 | 20 | 19 | 18  | 17 | 16 |     |
| R     | 0        |    |    |    |    |    |    |    | TXE | 0  |    |    |    | TXT | 0  |    | TXS |
| W     | [Shaded] |    |    |    |    |    |    |    |     |    |    |    |    |     |    |    |     |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1   | 0  | 0  | 0  | 0  | 0   | 0  | 0  |     |

| 0<br>WU_IE      | Wakeup Interrupt Enable<br>This bit is used to enable the low power wakeup interrupt.<br>0 Disabled<br>1 Enabled       |

## 51.4 Functional Description

This module can be broken down into functional sub-blocks as described below.

### 51.4.1 System Interface

The system interface block contains all the control and status registers to allow a core to interface to the module. These registers allow the processor to control the configuration and ascertain the capabilities of the module and, they control the module's operation.

### 51.4.2 DMA Engine

The USBHS module contains a local DMA engine. It is responsible for moving all of the data transferred over the USB between the module and system memory.

The DMA controllers must access control information and packet data from system memory. Control information is contained in link list based queue structures. The DMA controllers have state machines able to parse data structures defined in the EHCI specification. In host mode, the data structures are EHCI compliant and represent queues of transfers performed by the host controller, including the split-transaction requests that allow an EHCI controller to direct packets to FS and LS speed devices. In device mode, data structures are similar to those in the EHCI specification and used to allow device responses to be queued for each of the active pipes in the device.

### 51.4.3 FIFO RAM Controller

The FIFO RAM controller is used for context information and to control FIFOs between the protocol engine and the DMA controller. These FIFOs decouple the system processor/memory bus requests from the extremely tight timing required by USB.

The use of the FIFO buffers differs between host and device mode operation. In host mode, a single data channel is maintained in each direction through the buffer memory. In device mode, multiple FIFO channels are maintained for each of the active endpoints in the system.

In host mode, the USB OTG modules use 16-byte transmit buffers and 16-byte receive buffers. For the USB OTG module, device operation uses a single 16-byte receive buffer and a 16-byte transmit buffer for each endpoint.

## 51.5 Initialization/Application Information

This section discusses host operation, device data structures, device operation, and servicing interrupts.

### 51.5.1 Host Operation

Enhanced Host Controller Interface (EHCI) Specification defines the general operational model for a USB module in host mode. The EHCI specification describes the register-level interface for a host controller for USB Revision 2.0. It includes a description of the hardware/software interface between system software and host controller hardware. The next section has information about the initialization of the USB modules; however, full details of the EHCI specification are beyond the scope of this document.

### 51.5.2 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between device controller driver (DCD) software and the device controller. The interface consists of device queue heads and transfer descriptors.

#### Note

Software must ensure that data structures do not span a 4K-page boundary.

The USB OTG uses an array of device endpoint queue heads to organize device transfers. As shown in the next figure, there are two endpoint queue heads in the array for each device endpoint—one for IN and one for OUT. The EPLISTADDR provides a pointer to the first entry in the array.

**Figure 51-52. End Point Queue Head Organization**

### 51.5.2.1 Endpoint Queue Head

All transfers are managed in the device endpoint queue head (dQH). The dQH is a 48-byte data structure, but must align on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) copies into the overlay area of the dQH, which starts at the nextTD pointer and continues through the end of the buffer pointers. After a transfer is complete, the dTD status updates in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH acts as a staging area for the dTD so the device controller can access needed information with minimal latency.

The next figure shows the endpoint queue head structure.

**Table 51-58. Endpoint Queue Head Layout**

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |        |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | offset |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--------|

*Table continues on the next page...*

**Table 51-59. Endpoint Capabilities/Characteristics (continued)**

| Field                          | Description  |   |                                      |   |                                 |
|--------------------------------|--|---|--------------------------------------|---|---------------------------------|
| 29                             | Zero length termination select. This bit is ignored in isochronous transfers.  |   |                                      |   |                                 |
| ZLT                            | <p>Clearing this bit enables the hardware to automatically append a zero length packet when the following conditions are true:</p> <ul style="list-style-type: none"> <li>• The packet transmitted equals maximum packet length</li> <li>• The dTD has exhausted the field Total Bytes</li> </ul> <p>After this the dTD retires. When the device is receiving, if the last packet length received equals the maximum packet length and the total bytes is zero, it waits for a zero length packet from the host to retire the current dTD.</p> <p>Setting this bit disables the zero length packet. When the device is transmitting, the hardware does not append any zero length packet. When receiving, it does not require a zero length packet to retire a dTD whose last packet was equal to the maximum packet length packet. The dTD is retired as soon as Total Bytes field goes to zero, or a short packet is received.</p> <table border="1"> <tr> <td>0</td> <td>Enable zero length packet (default).</td> </tr> <tr> <td>1</td> <td>Disable the zero length packet.</td> </tr> </table> <p><b>Note:</b> Each transfer is defined by one dTD, so the zero length termination is for each dTD. In some software application cases, the logic transfer does not fit into only one dTD, so it does not make sense to add a zero length termination packet each time a dTD is consumed. On those cases we recommend to disable the ZLT feature, and use software to generate the zero length termination.</p> | 0 | Enable zero length packet (default). | 1 | Disable the zero length packet. |
| 0                              | Enable zero length packet (default).   |   |                                      |   |                                 |
| 1                              | Disable the zero length packet.  |   |                                      |   |                                 |
| 28–27                          | Reserved. Reserved for future use and must be cleared.   |   |                                      |   |                                 |
| 26–16<br>Maximum Packet Length | Maximum packet length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).   |   |                                      |   |                                 |
| 15<br>IOS                      | Interrupt on setup (IOS). This bit used on control type endpoints indicates if USBSTS[UI] is set in response to a setup being received.  |   |                                      |   |                                 |
| 14–0                           | Reserved. Reserved for future use and must be cleared.   |   |                                      |   |                                 |

### 51.5.2.1.2 Current dTD Pointer (Offset = 0x4)

The device controller uses the current dTD pointer to locate transfer in progress. This word is for USB OTG (hardware) use only and should not be modified by DCD software.

**Table 51-60. Current dTD Pointer**

| Field               | Description   |
|---------------------|---|
| 31–5<br>Current dtd | Current dtd. This field is a pointer to the dTD represented in the transfer overlay area. This field is modified by the device controller to next dTD pointer during endpoint priming or queue advance. |
| 4–0                 | Reserved. Reserved for future use and must be cleared.  |

### 51.5.2.1.3 Transfer Overlay (Offset = 0x8–0x20)

The seven entries in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, it does not read the associated endpoint.

After an endpoint is readied, the dTD is copied into this queue head overlay area by the device controller. Until a transfer expires, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller writes the results back to the original transfer descriptor and advance the queue.

### 51.5.2.1.4 Setup Buffer (Offset = 0x28–0x2C)

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID. Refer to [Control Endpoint Operation](#) for information on the procedure for reading the setup buffer

#### Note

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head receives setup data packets.

**Table 51-61. Multiple Mode Control**

| Offset | Field                  | Description  |
|--------|------------------------|--|
| 0x28   | 31–0<br>Setup Buffer 0 | Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller software reads. |
| 0x2C   | 31–0<br>Setup Buffer 1 | Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller software reads. |

### 51.5.2.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data sent/received for a given transfer. The DCD software should not attempt to modify any field in an active dTD except the next dTD pointer.

**Table 51-62. Endpoint Transfer Descriptor (dTD)**

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |            |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | off<br>set |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|------------|

Table continues on the next page...

**Table 51-62. Endpoint Transfer Descriptor (dTD) (continued)**

|   |             |  |  |  |                |              |   |   |   |       |   |   |        |   |      |      |
|---|-------------|--|--|--|----------------|--------------|---|---|---|-------|---|---|--------|---|------|------|
| Next dTD Pointer                                    |             |  |  |  |                |              |   |   |   |       | 0 | 0 | 0      | 0 | T    | 0x00 |
| 0   | Total Bytes |  |  |  |                | io           | 0 | 0 | 0 | MultO | 0 | 0 | Status |   |      | 0x04 |
| Buffer Pointer (Page 0)                             |             |  |  |  | Current Offset |              |   |   |   |       |   |   |        |   | 0x08 |      |
| Buffer Pointer (Page 1)                             |             |  |  |  | 0              | Frame Number |   |   |   |       |   |   |        |   |      | 0x0C |
| Buffer Pointer (Page 2)                             |             |  |  |  | 0              | 0            | 0 | 0 | 0 | 0     | 0 | 0 | 0      | 0 | 0    | 0x10 |
| Buffer Pointer (Page 3)                             |             |  |  |  | 0              | 0            | 0 | 0 | 0 | 0     | 0 | 0 | 0      | 0 | 0    | 0x14 |
| Buffer Pointer (Page 4)                             |             |  |  |  | 0              | 0            | 0 | 0 | 0 | 0     | 0 | 0 | 0      | 0 | 0    | 0x18 |
| Device controller read/write; all others read-only. |             |  |  |  |                |              |   |   |   |       |   |   |        |   |      |      |

### 51.5.2.2.1 Next dTD Pointer (Offset = 0x0)

The next dTD pointer is used to point the device controller to the next dTD in the linked list.

**Table 51-63. Next dTD Pointer**

| Field                    | Description  |
|--------------------------|--|
| 31–5<br>Next dTD pointer | Next dTD pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.                         |
| 4–1                      | Reserved. Reserved for future use and must be cleared.   |
| 0<br>T                   | Terminate. This bit indicates to the device controller no more valid entries exist in the queue.<br>0=Pointer is valid (points to a valid transfer element descriptor).<br>1=pointer is invalid. |

### 51.5.2.2.2 dTD Token (Offset = 0x4)

The dTD token is used to specify attributes for the transfer including the number of bytes to read or write and the status of the transaction.

**Table 51-64. dTD Token**

| Field | Description  |
|-------|--|
| 31    | Reserved. Reserved for future use and must be cleared. |

*Table continues on the next page...*

**Table 51-64. dTD Token (continued)**

| Field                | Description   |
|----------------------|---|
| 30–16<br>Total Bytes | <p>Total bytes. This field specifies the total number of bytes moved with this transfer descriptor. This field decrements by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K(0x5000). This is the maximum number of bytes 5 page pointers can access. Although possible to create a transfer up to 20K, this assumes the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (0x4000).</p> <p><b>Note:</b> Larger transfer sizes can be supported, but require disabling ZLT and using multiple dTDs.</p> <p>If the value of the field is 0 when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p> <p>For IN transfers it is not a requirement for total bytes to transfer be an even multiple of the maximum packet length. If software builds such a transfer descriptor for an IN transfer, the last transaction is always less than maximum packet length.</p> <p>For OUT transfers the total bytes must be evenly divisible by the maximum packet length.</p> |
| 15<br>IOC            | Interrupt on complete. Indicates if USBSTS[UI] is set in response to device controller finished with this dTD.  |
| 14–12                | Reserved. Reserved for future use and must be cleared.  |
| 11–10<br>MultO       | <p>Multiplier Override. This field can possibly transmit-ISOs (ISO-IN) to override the multiplier in the QH. This field must be 0 for all packet types not transmit-ISO.</p> <p>For example, if QH.MULT equals 3; Maximum packet size equals 8; Total Bytes equals 15; MultiO equals 0 [default], then three packets are sent: {Data2(8); Data1(7); Data0(0)}.</p> <p>If QH.MULT equals 3; Maximum packet size equals 8; Total Bytes equals 15; MultO equals 2, then two packets are sent: {Data1(8); Data0(7)}</p> <p>For maximal efficiency, software must compute MultO equals greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes equals 0; then MultO must be 1.</p> <p><b>Note:</b> Non-ISO and Non-TX endpoints must set MultO equals 00.</p>  |
| 9–8                  | Reserved. Reserved for future use and must be cleared.  |

*Table continues on the next page...*

**Table 51-64. dTD Token (continued)**

| Field         | Description   |  |
|---------------|---|--|
| 7–0<br>Status | Status. Device controller communicates individual command execution states back to the DCD software. This field contains the status of the last transaction performed on this dTD. The bit encodings are: |  |
|               | Bit   | Status Field Description   |
|               | 7   | Active. Set by software to enable the execution of transactions by the device controller.  |
|               | 6   | Halted. Set by the device controller during status updates to indicate a serious error has occurred at the device/endpoint addressed by this dTD. Any time a transaction results in the halted bit being set, the active bit is also cleared.  |
|               | 5   | Data Buffer Error. Set by the device controller during status update to indicate the device controller is unable to maintain the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). |
|               | 4   | Reserved.  |
|               | 3   | Transaction Error. Set by the device controller during status update in case the device did not receive a valid response from the host (time-out, CRC, bad PID).   |
|               | 2–0   | Reserved.  |

### 51.5.2.2.3 dTD Buffer Page Pointer List (Offset = 0x8–0x18)

The buffer page pointer list of a device element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

**Table 51-65. Buffer Page Pointer List**

| Field                    | Description   |
|--------------------------|---|
| 31–12<br>Buffer Pointer  | Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems typically set the buffer pointers to a series of incrementing integers.     |
| 0;11–0<br>Current Offset | Current Offset. Offset into the 4kB buffer where the packet begins.   |
| 1;10–0<br>Frame Number   | Frame Number. Written by the device controller to indicate the frame number a packet finishes in. Typically correlates relative completion times of packets on an ISO endpoint. |

## 51.5.3 Device Operation

The device controller performs data transfers using a set of linked list transfer descriptors pointed to by a queue head. The next sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

### 51.5.3.1 Port State and Control

From a chip or system reset, the USB OTG module enters the powered state. A transition from the powered state to the attach state occurs when the USBCMD[RS] bit is set. After receiving a reset on the bus, the port enters the defaultFS or defaultHS state in accordance with the protocol reset described in Appendix C.2 of the *Universal Serial Bus Specification, Revision 2.0*. The next figure depicts the state of a USB 2.0 device.

**Figure 51-53. USB 2.0 Device States**

States powered, attach, defaultFS/HS, suspendFS/HS are implemented in the USB OTG, and they are communicated to the DCD using these status bits:

**Table 51-66. Device Controller State Information Bits**

| Bit                      | Register |
|--------------------------|----------|
| DC Suspend (SLI)         | USBSTS   |
| USB Reset Received (URI) | USBSTS   |
| Port Change Detect (PCI) | USBSTS   |
| High-Speed Port (PSPD)   | PORTSCn  |

DCD software must maintain a state variable to differentiate between the defaultFS/HS state and the address/configured states. Change of state from default to the address and configured states is part of the enumeration process described in the device framework section of the USB 2.0 specification.

As a result of entering the address state, the DCD must program the device address register (DEVICEADDR).

Entry into the configured state indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the EPCR<sub>n</sub> registers and initializing the associated queue heads.

### 51.5.3.1.1 Bus Reset

The host uses a bus reset to initialize downstream devices. When a bus reset is detected, USB OTG controller renegotiates its attachment speed, resets the device address to 0, and notifies the DCD by interrupt (assuming the USB reset interrupt enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and the device controller cancels any primed transactions. The concept of priming is clarified below, but when a reset is received, the DCD must perform:

1. Clear all setup token semaphores by reading the EPSETUPSR register and writing the same value back to the EPSETUPSR register.
2. Clear all the endpoint complete status bits by reading the EPCOMPLETE register and writing the same value back to the EPCOMPLETE register.
3. Cancel all primed status by waiting until all bits in the EPPRIME are 0 and then writing 0x000F\_000F to EPFLUSH.
4. Read the reset bit in the PORTSC<sub>n</sub> register and make sure it remains active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset clean-up before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare).

- a. Setting USBCMD[RST] bit can perform a hardware reset.

### Note

A hardware reset causes the device to detach from the bus by clearing the USBCMD[RS] bit. Therefore, the DCD must completely re-initialize the USB OTG after a hardware reset.

5. Free all allocated dTDs because the device controller no longer executes them. If this is the first time the DCD processes a USB reset event, it is likely no dTDs have been allocated.
6. At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.
7. After a port change detect, the device has reached the default state and the DCD can read the PORTSC<sub>n</sub> register to determine if the device operates in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the chapter 9 Device Framework of the USB specification.

#### 51.5.3.1.2 Suspend/Resume

To conserve power, USB OTG module automatically enters the suspended state when no bus traffic is observed for a specified period. When suspended, the module maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend any time they are powered, regardless if they are assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

The USB OTG module exits suspend mode when there is bus activity. It may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. The USB OTG is capable of remote wake-up signaling. When the USB OTG is reset, remote wake-up signaling must be disabled.

### 51.5.3.1.2.1 Suspend Operational Model

The USB OTG moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, an interrupt notifies the DCD (assuming device controller suspend interrupt is enabled, USBINTR[SLE] is set). When the PORTSCn[SUSP] is set, the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation. Find information on the bus power limits in suspend state in USB 2.0 specification.

### 51.5.3.1.2.2 Resume

If the USB OTG is suspended, its operation resumes when any non-idle signaling is received on its upstream facing port. In addition, the USB OTG can signal the system to resume operation by forcing resume signaling to the upstream port. Setting the PORTSCn[FPR] bit while the device is in suspend state sends resume signaling upstream. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

#### Note

Before use of resume signaling, the host must enable it by using the set feature command defined in chapter 9 Device Framework of the USB 2.0 specification.

## 51.5.3.2 Managing Endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. Combination of the endpoint number and the endpoint direction specifies endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints are supported by USB include bulk, interrupt, and isochronous. Each endpoint type has specific behavior related to packet response and error managing. Find more detail on endpoint operation in the USB 2.0 specification.

The USB OTG supports up to four endpoint specified numbers. The DCD can enable, disable, and configure each endpoint.

Each endpoint direction is essentially independent and can have differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0, for example, is always a control endpoint and uses both directions.

Each endpoint direction requires a queue head allocated in memory. If the maximum is four endpoint numbers (one for each endpoint direction used by the device controller), eight queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

### 51.5.3.2.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to the appropriate  $EPCR_n$  register. Each  $EPCR_n$  is split into an upper and lower half. The lower half of  $EPCR_n$  configures the receive or OUT endpoint, and the upper half configures the corresponding transmit or IN endpoint. Control endpoints must be configured the same in the upper and lower half of the  $EPCR_n$  register; otherwise, behavior is undefined. The next table shows how to construct a configuration word for endpoint initialization.

**Table 51-67. Device Controller Endpoint Initialization**

| Field                          | Value   |
|--------------------------------|---|
| Data Toggle Reset (TXR, RXR)   | 1 Synchronize the data PIDs                             |
| Data Toggle Inhibit (TXI, RXI) | 0 PID sequencing disabled                               |
| Endpoint Type (TXT, RXT)       | 00 Control<br>01 Isochronous<br>10 Bulk<br>11 Interrupt |
| Endpoint Stall (TXS, RXS)      | 0 Not stalled   |

### 51.5.3.2.2 Stalling

There USB OTG has two occasions it may need to return to the host a STALL:

- The first is the functional stall, a condition set by the DCD as described in the USB 2.0 Device Framework chapter. A functional stall is used only on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the  $EPCR_n$  register associated with the given endpoint and the given direction. In

a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

- A protocol stall, unlike a function stall, is used on control endpoints and automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, DCD must enable the stall bits as a pair (TXS and RXS bits). A single write to the EPCR<sub>n</sub> register can ensure both stall bits are set at the same instant.

### Note

Any write to the EPCR<sub>n</sub> register during operational mode must preserve the endpoint type field (perform a read-modify-write).

**Table 51-68. Device Controller Stall Response Matrix**

| USB Packet   | Endpoint Stall Bit | Effect on Stall bit | USB Response |
|--|--------------------|---------------------|--------------|
| SETUP packet received by a non-control endpoint.       | N/A                | None                | STALL        |
| IN/OUT/PING packet received by a non-control endpoint. | 1                  | None                | STALL        |
| IN/OUT/PING packet received by a non-control endpoint. | 0                  | None                | ACK/NAK/NYET |
| SETUP packet received by a control endpoint.           | N/A                | Cleared             | ACK          |
| IN/OUT/PING packet received by a control endpoint      | 1                  | None                | STALL        |
| IN/OUT/PING packet received by a control endpoint.     | 0                  | None                | ACK/NAK/NYET |

### 51.5.3.2.3 Data Toggle

Data toggle maintains data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

#### 51.5.3.2.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by setting the data toggle reset bit in the EPCR<sub>n</sub> register. This should only happen when configuring/initializing an endpoint or returning from a STALL condition.

#### 51.5.3.2.3.2 Data Toggle Inhibit

This feature is for test purposes only and must never be used during normal device controller operation.

Setting the data toggle inhibit bit causes the USB OTG module to ignore the data toggle pattern normally sent and accepts all incoming data packets regardless of the data toggle state.

In normal operation, the USB OTG checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If the data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the USB OTG from re-sending the same packet, the device controller responds to the error packet by acknowledging it with an ACK or NYET response.

### 51.5.3.3 Packet Transfers

The host initiates all transactions on the USB bus and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

A USB host sends requests to the USB OTG in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, expect the host to send IN requests to that endpoint. This USB OTG module prepares packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as priming the endpoint. This term appears throughout the documentation to describe the USB OTG operation so the DCD is built properly. Further, the term flushing describes the action of clearing a packet queued for execution.

#### 51.5.3.3.1 Priming Transmit Endpoints

Priming a transmit endpoint causes the device controller to fetch the device transfer descriptor (dTDD) for the transaction pointed to by the device queue head (dQH). After the dTDD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTDD. Storing the dTDD in the dQH allows the device controller to fetch the operating context needed to manage a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTDD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO splits into virtual channels so the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the EPSR register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of high-speed USB.

### 51.5.3.3.2 Priming Receive Endpoints

Priming receives endpoints identical to priming of transmit endpoints from the point of view of the DCD. The major difference in the operational model at the device controller is no data movement of the leading packet data because the data is to be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

### 51.5.3.3.3 Interrupt/Bulk Endpoint Operation

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

A dTD is retired by the device controller when the packets described in the transfer descriptor are completed. Each dTD describes N packets to transfer according to the USB variable length transfer protocol. The formula below and the next table describe how the device controller computes the number and length of the packets sent/received by the USB vary according to the total number of bytes and maximum packet length. See [Endpoint Capabilities/Characteristics \(Offset = 0x0\)](#) for details on the ZLT bit.

With zero-length termination (ZLT) cleared:

$$N = \text{INT}(\text{number of bytes}/\text{max. packet length}) + 1$$

With zero-length termination (ZLT) set:

$$N = \text{MAXINT}(\text{number of bytes}/\text{max. packet length})$$

**Table 51-69. Variable Length Transfer Protocol Example (ZLT=0)**

| Bytes (dTD) | Max. Packet Length (dQH) | N | P1  | P2  | P3 |
|-------------|--------------------------|---|-----|-----|----|
| 511         | 256                      | 2 | 256 | 255 | —  |
| 512         | 256                      | 3 | 256 | 256 | 0  |
| 512         | 512                      | 2 | 512 | 0   | —  |

**Table 51-70. Variable Length Transfer Protocol Example (ZLT=1)**

| Bytes (dTD) | Max. Packet Length (dQH) | N | P1  | P2  | P3 |
|-------------|--------------------------|---|-----|-----|----|
| 511         | 256                      | 2 | 256 | 255 | —  |
| 512         | 256                      | 2 | 256 | 256 | —  |
| 512         | 512                      | 1 | 512 | —   | —  |

**Note**

The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described in the dTD successfully transmit. Total bytes in dTD equal 0 when this occurs.

RX-dTD is complete when:

- All packets described in the dTD are successfully received. Total bytes in dTD equal 0 when this occurs.
- A short packet (number of bytes < maximum packet length) was received.

This is a successful transfer completion; DCD must check the total bytes field in the dTD to determine the number of bytes remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.

- A long packet was received (number of bytes > maximum packet size) or (total bytes received > total bytes specified).

This is an error condition. The device controller discards the remaining packet and set the buffer error bit in the dTD. In addition, the endpoint flushes and the USBERR interrupt becomes active.

**Note**

Disabling zero-length packet termination allows transfers larger than the total bytes field spanning across two or more dTDs.

Upon successful completion of the packet(s) described by the dTD, the active bit in the dTD is cleared and the next pointer is followed when the terminate bit is clear. When the terminate bit is set, USB OTG flushes the endpoint/direction and ceases operations for that endpoint/direction.

Upon unsuccessful completion of a packet (see long packet above), the dQH is left pointing to the dTD in error. To recover from this error condition, DCD must properly re-initialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

**Note**

All packet level errors, such as a missing handshake or CRC error, are retried automatically by the device controller. There is no required interaction with the DCD for managing such errors.

**Table 51-71. Interrupt/Bulk Endpoint Bus Response Matrix**

| Token Type | Stall  | Not Primed | Primed                          | Underflow             | Overflow |
|------------|--------|------------|---------------------------------|-----------------------|----------|
| Setup      | Ignore | Ignore     | Ignore                          | N/A                   | N/A      |
| In         | STALL  | NAK        | Transmit                        | BS Error <sup>1</sup> | N/A      |
| Out        | STALL  | NAK        | Receive + NYET/ACK <sup>2</sup> | N/A                   | NAK      |
| Ping       | STALL  | NAK        | ACK                             | N/A                   | N/A      |
| Invalid    | Ignore | Ignore     | Ignore                          | Ignore                | Ignore   |

1. Force bit stuff error
2. NYET/ACK — NYET unless the transfer descriptor has packets remaining according to the USB variable length protocol then ACK.

### 51.5.3.3.4 Control Endpoint Operation

#### 51.5.3.3.4.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase.

Setup packet managing:

- Disable setup lockout by setting the setup lockout mode bit (USBMODE[SLOM]), once at initialization. Setup lockout is not necessary when using the tripwire as described below.

**Note**

Leaving the setup lockout mode cleared results in a potential compliance issue.

- After receiving an interrupt and inspecting EPSETUPSR to determine a setup packet was received on a particular pipe:

1. Write 1 to clear corresponding bit in EPSETUPSR.
2. Set the setup tripwire bit (USBCMD[SUTW]).
3. Duplicate contents of dQH.SetupBuffer into local software byte array.
4. Read the USBCMD[SUTW] bit. If set, continue; if cleared, goto 2)
5. Clear the USBCMD[SUTW] bit.
6. Poll until the EPSETUPSR bit clears.
7. Process setup packet using the local software byte array copy and execute status/handshake phases.

### Note

After receiving a new setup packet, status and/or handshake phases may remain pending from a previous control sequence. These should be flushed and de-allocated before linking a new status and/or handshake dTD for the most recent setup packet.

#### 51.5.3.3.4.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet is not received by reading the EPSETUPSR register immediately verifying that the prime had completed. A prime completes when the associated bit in the EPPRIME register is cleared and the associated bit in the EPSR register is set. If the EPPRIME bit goes to 0 and the EPSR bit is not set, the prime fails. This can only happen because of improper setup of the dQH, dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after the EPPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must re-interpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller automatically clears the prime status (EPSR) to enforce data coherency with the setup packet.

### Note

Error managing of data phase packets is the same as bulk packets described previously.

### 51.5.3.3.4.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the EPSETUPSR as described above in the data phase.

#### Note

Error managing of status phase packets is the same as bulk packets described previously.

### 51.5.3.3.4.4 Control Endpoint Bus Response Matrix

The next table shows the device controller response to packets on a control endpoint according to the device controller state.

**Table 51-72. Control Endpoint Bus Response Matrix**

| Token Type | Endpoint State |            |                                     |                       |                      | Setup Lockout |
|------------|----------------|------------|-------------------------------------|-----------------------|----------------------|---------------|
|            | Stall          | Not Primed | Primed                              | Underflow             | Overflow             |               |
| Setup      | ACK            | ACK        | ACK                                 | N/A                   | SYSEERR <sup>1</sup> |               |
| In         | STALL          | NAK        | Transmit                            | BS Error <sup>2</sup> | N/A                  | N/A           |
| Out        | STALL          | NAK        | Receive + NYET/<br>ACK <sup>3</sup> | N/A                   | NAK                  | N/A           |
| Ping       | STALL          | NAK        | ACK                                 | N/A                   | N/A                  | N/A           |
| Invalid    | Ignore         | Ignore     | Ignore                              | Ignore                | Ignore               | Ignore        |

1. SYSEERR — System error must never occur when the latency FIFOs are correctly sized and the DCD is responsive.
2. Force bit stuff error.
3. NYET/ACK — NYET unless the transfer descriptor has packets remaining according to the USB variable length protocol then ACK.

### 51.5.3.3.5 Isochronous Endpoint Operation

Isochronous endpoints used for real-time scheduled delivery of data, and their operational model is significantly different than the host throttled bulk, interrupt, and control data pipes. Real time delivery by the USB OTG is accomplished by:

- Exactly MULT packets per (micro)frame are transmitted/received.

#### Note

MULT is a two-bit field in the device queue head. Isochronous endpoints do not use the variable length packet protocol.

- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If ISO-dTD remains active after that frame, ISO-dTD holds ready until executed or canceled by the DCD.

The USB OTG in host mode uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for control/bulk/interrupt endpoints is also used for isochronous endpoints. The difference is in the managing of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint becomes primed only after a SOF is received. After the DCD writes the prime bit, the prime bit clears as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD, but occurs so the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. After an ISO transaction is started in a (micro)frame, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, and the device controller retires the current ISO-dTD and move to the next ISO-dTD.

Fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction stays primed indefinitely. This means it is up to software must discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error managing. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the transaction error bit and the data is stored as usual for the application software to sort out.

- TX packet retired:
  - MULT counter reaches zero.
  - Fulfillment error (transaction error bit is set):

- # packets occurred > 0 AND # packets occurred < MULT

### Note

For TX-ISO, MULT counter can be loaded with a lesser value in the dTD multiplier override field. If the multiplier override field is zero, the MULT counter initializes to the multiplier in the QH.

- RX packet retired:
  - MULT counter reaches zero.
  - Non-MDATA data PID is received
  - Overflow error:
    - Packet received is > maximum packet length. (Buffer Error bit is set)
    - Packet received exceeds total bytes allocated in dTD. (Buffer Error bit is set)
  - Fulfillment error (Transaction Error bit is set):
    - # packets occurred > 0 AND # packets occurred < MULT
  - CRC error (Transaction Error bit is set)

### Note

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation, DCD must ensure the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

#### 51.5.3.3.5.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro)frame number (FRINDEX register) can act as a marker. To cause a packet transfer to occur at a specific (micro)frame number (N), the DCD must interrupt on SOF during frame N-1. When the FRINDEX equals N-1, the DCD must write the prime bit. The USB OTG primes the isochronous endpoint in (micro)frame N-1 so the device controller executes delivery during (micro)frame N.

## CAUTION

Priming an endpoint towards the end of (micro)frame N-1 does not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

### 51.5.3.3.5.2 Isochronous Endpoint Bus Response Matrix

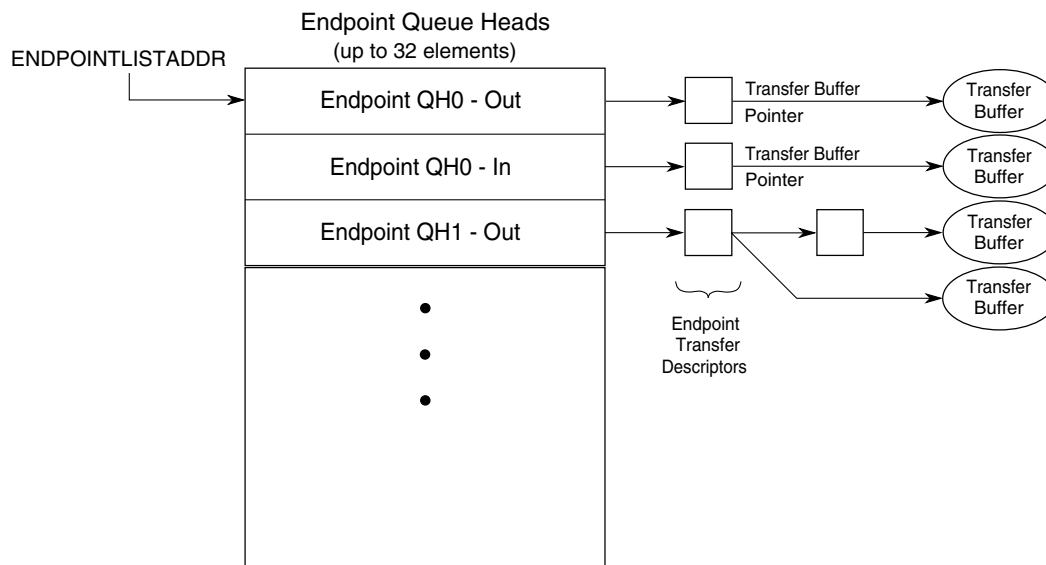

**Table 51-73. Isochronous Endpoint Bus Response Matrix**

| Token Type     | Stall                    | Not Primed  | Primed   | Underflow             | Overflow    |
|----------------|--------------------------|-------------|----------|-----------------------|-------------|
| <b>Setup</b>   | STALL                    | STALL       | STALL    | N/A                   | N/A         |
| <b>In</b>      | NULL <sup>1</sup> Packet | NULL Packet | Transmit | BS Error <sup>2</sup> | N/A         |
| <b>Out</b>     | Ignore                   | Ignore      | Receive  | N/A                   | Drop Packet |
| <b>Ping</b>    | Ignore                   | Ignore      | Ignore   | Ignore                | Ignore      |
| <b>Invalid</b> | Ignore                   | Ignore      | Ignore   | Ignore                | Ignore      |

1. Zero length packet
2. Force bit stuff error

### 51.5.3.4 Managing Queue Heads

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device transfer descriptor (dTD). An area of memory pointed to by EPLISTADDR contains a group of all dQH's in a sequential list (see the next figure). The even elements in the list of dQH's receive endpoints (OUT/SETUP) and the odd elements transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. After the dTD retires, it is no longer part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers no longer exist within the queue head after the dTD is retired (see [Software Link Pointers](#)).

**Figure 51-54. Endpoint Queue Head Diagram**

In addition to current and next pointers and the dTD overlay examined in [Packet Transfers](#) the dQH also contains the following parameters for the associated endpoint: multiplier, maximum packet length, and interrupt on setup. The next section includes demonstration of complete initialization of the dQH including these fields.

### 51.5.3.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB specification chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required for bandwidth with the USB specification chapter 9 protocol. In FS mode, the multiplier field can only be 1 for ISO endpoints.
- Set the next dTD terminate bit field.
- Clear the active bit in the status field.
- Clear the halt bit in the status field.

#### Note

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

### 51.5.3.4.2 Setup Transfers Operation

As discussed in [Control Endpoint Operation](#) setup transfers require special treatment by the DCD. A setup transfer does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should manage the setup transfer by:

1. Copying setup buffer contents from dQH-RX to software buffer.
2. Acknowledging setup backup by writing a 1 to the corresponding bit in the EPSETUPSR register.

#### Note

The acknowledge must occur before continuing to process the setup packet. After acknowledge occurs, DCD must not attempt to access the setup buffer in dQH-RX. Only local software copy should be examined.

3. Checking for pending data or status dTD's from previous control transfers and flushing if any exist as discussed in [Flushing/De-priming an Endpoint](#).

#### Note

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

4. Decoding setup packet and prepare data phase (optional) and status phase transfer as required by the USB specification chapter 9 or application specific protocol.

### 51.5.3.5 Managing Transfers with Transfer Descriptors

### 51.5.3.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD executed. The operations described in the next section for managing dTDs assumes DCD can reference the head and tail of the dTD linked list.

#### Note

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but DCD must continue maintaining the pointers.

**Figure 51-55. Software Link Pointers**

#### Note

Check the status of each dTD to determine completed status.

### 51.5.3.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate a 32-byte dTD block of memory aligned to 32-byte boundaries. The last 5 bits of the address must equal 00000.

Write the following fields:

1. Initialize the first 7 entries (28 bytes) to 0.
2. Set the terminate bit.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete bit if desired.
5. Initialize the status field with the active bit set, and all remaining status bits cleared.

6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

### 51.5.3.5.3 Executing a Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure that manages the event where the device controller reaches the end of the dTD list. At the same time, a new dTD is added to the end of the list.

Determine whether the linked list is empty:

Check the DCD driver to see if the pipe is empty (internal representation of the linked list should indicate if any packets are outstanding)

Case 1: Link list is empty

1. Write dQH next pointer AND dQH terminate bit to 0 as a single 32-bit operation.
2. Clear active and halt bit in dQH (in case set from a previous error).
3. Prime endpoint by writing 1 to the correct bit position in the EPPRIME register.

Case 2: Link list is not empty

1. Add dTD to end of the linked list.
2. Read correct prime bit in EPPRIME - if set, DONE.
3. Set the USBCMD[ATDTW] bit.
4. Read correct status bit in EPSR, and store in a temporary variable for later.
5. Read the USBCMD[ATDTW] bit:
  - If clear, go to 3.
  - If set, continue to 6.
6. Clear the USBCMD[ATDTW] bit.
7. If status bit read in step 4 is 1 DONE.
8. If status bit read in step 4 is 0 then go to case 1, step 1.

#### 51.5.3.5.4 Transfer Completion

After a dTD is initialized and the associated endpoint is primed, the device controller executes the transfer upon the host-initiated request. The DCD is notified with a USB interrupt if the interrupt-on-complete bit was set, or alternatively, the DCD can poll the endpoint complete register to determine when the dTD had been executed. After a dTD is executed, DCD can check the status bits to determine success or failure.

#### CAUTION

Multiple dTDs can be completed in a single endpoint complete notification. After clearing the notification, the DCD must search the dTD linked list and retire all finished (active bit cleared) dTDs.

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0, Halted = 0, Transaction error = 0, Data buffer error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in [Device Error Matrix](#).

In addition to checking the status bit, the DCD must read the transfer bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred decrements by the actual bytes transferred. For transmit packets, a packet is only complete after the actual bytes reaches zero. However, for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

#### 51.5.3.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush or de-prime endpoints during a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The DCD can use this procedure to stop a transfer in progress:

1. Set the corresponding bit(s) in the EPFLUSH register.
2. Wait until all bits in the EPFLUSH register are cleared.

#### Note

This operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read the EPSR register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now cleared. If the corresponding bits are set after step #2 has finished, flush failed as described below:

In very rare cases, a packet is in progress to the particular endpoint when commanded to flush using EPFLUSH. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint successfully flushes.

### 51.5.3.5.6 Device Error Matrix

The following table summarizes packet errors not automatically managed by the USB OTG module.

**Table 51-74. Device Error Matrix**

| Error                 | Direction | Packet Type | Data Buffer Error Bit | Transaction Error Bit |
|-----------------------|-----------|-------------|-----------------------|-----------------------|
| Data Buffer Overflow  | RX        | Any         | 1                     | 0                     |
| ISO Packet Error      | RX        | ISO         | 0                     | 1                     |
| ISO Fulfillment Error | Both      | ISO         | 0                     | 1                     |

The device controller manages all errors on bulk/control/interrupt endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated.

**Table 51-75. Error Descriptions**

|                       |  |
|-----------------------|--|
| Overflow              | Number of bytes received exceeded max. packet size or total buffer length.<br><b>Note:</b> This error also sets the halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, those are not executed.  |
| ISO Packet Error      | CRC error on received ISO packet. Contents not guaranteed correct.   |
| ISO Fulfillment Error | Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery, DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one (micro)frame. During the dead (micro)frame, the device controller reports error on the pipe and primes for the following frame. |

## 51.5.4 Servicing Interrupts

The interrupt service routine must understand there are high frequency, low frequency, and error operations to order accordingly.

### 51.5.4.1 High Frequency Interrupts

In particular, high frequency interrupts must be managed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

**Table 51-76. Interrupt Managing Order**

| Execution Order | Interrupt                               | Action  |
|-----------------|---|---|
| 1a              | USB Interrupt <sup>1</sup><br>EPSETUPSR | Copy contents of setup buffer and acknowledge setup packet (as indicated in <a href="#">Managing Queue Heads</a> ). Process setup packet according to USB specification chapter 9 or application specific protocol. |
| 1b              | USB Interrupt<br>EPCOMPLETE             | Manage completion of dTD as indicated in <a href="#">Managing Queue Heads</a> .   |
| 2               | SOF Interrupt                           | Action as deemed necessary by application. This interrupt may not have a use in all applications.   |

1. It is likely multiple interrupts stack up on any call to the interrupt service routine and during interrupt service routine.

#### 51.5.4.1.1 Low Frequency Interrupts

The low frequency events include the following interrupts. These interrupts can be managed in any order because they do not occur often in comparison to the high-frequency interrupts.

**Table 51-77. Low Frequency Interrupt Events**

| Interrupt              | Action  |
|------------------------|---|
| Port Change            | Change software state information.                                  |
| Sleep Enable (Suspend) | Change software state information. Low power managing as necessary. |
| Reset Received         | Change software state information. Abort pending transfers.         |

#### 51.5.4.1.2 Error Interrupts

Error interrupts are least frequent and should be placed last in the interrupt service routine.

**Table 51-78. Error Interrupt Events**

| Interrupt            | Action   |
|----------------------|--|
| USB Error Interrupt. | This error is redundant because it combines USB interrupt and an error status in the dTD. The DCD more aptly manages packet-level errors by checking the dTD status field upon receipt of USB interrupt (w/ EPCOMPLETE). |

*Table continues on the next page...*

**Table 51-78. Error Interrupt Events (continued)**

| Interrupt    | Action  |
|--------------|---|
| System Error | Unrecoverable error. Immediate reset of module; free transfers buffers in progress and restart the DCD. |

### 51.5.5 Deviations from the EHCI Specifications

The host mode operation of the USB OTG module is nearly EHCI-compatible with a few minor differences. For the most part, the modules conform to the data structures and operations described in Section 3, "Data Structures," and Section 4, "Operational Model," in the EHCI specification. The particulars of the deviations occur in the following areas:

- Embedded transaction translator—Allows direct attachment of HS, FS and LS devices in host mode without the need for a companion controller.
- Device operation—In host mode, the device operational registers are generally disabled; therefore, device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface—The module does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

For the purposes of the USB OTG implementing a dual-role host/device controller with support for OTG applications, it is necessary to deviate from the EHCI specification. Device and OTG operation are not specified in the EHCI specification, and thus the implementation supported in the USB OTG module is proprietary.

#### 51.5.5.1 Embedded Transaction Translator Function

The USB host mode supports directly connected high-, full- and low-speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high-speed hub transaction translator. Although there is no separate transaction translator block in the system, the transaction translator function normally associated with a high-speed hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models existing in the EHCI specification to support full- and low-speed devices.

### 51.5.5.1.1 Capability Registers

These additions to the capability registers support the embedded Transaction translator function:

- N\_TT added to HSCPARAMS - Host Controller Structural Parameters
- N\_PTT added to HSCPARAMS - Host Controller Structural Parameters

Refer to the section for the HCSPARAMS register for usage information.

### 51.5.5.1.2 Operational Registers

These additions to the operational registers support the embedded TT:

- Addition of the TTCTRL register.
- Addition of a two-bit port speed (PSPD) field to the PORTSC<sub>n</sub> register.

### 51.5.5.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects a full-speed (FS) or low-speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable is set only in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a high-speed connection (chirp completes successfully).

The module always sets the port enable bit after the port reset operation regardless of the result of the host device chirp result, and the resulting port speed is indicated by the PORTSC<sub>n</sub>[PSPD] field. Therefore, the standard EHCI host controller driver requires an alteration to manage directly connected full- and low-speed devices or hubs. The change is a fundamental one summarized in the next table.

**Table 51-79. Functional Differences Between EHCI and EHCI with Embedded TT**

| Standard EHCI  | EHCI with embedded Transaction Translator  |
|--|--|
| After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.  | After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSC <sub>n</sub> .   |
| FS and LS devices are assumed to be downstream from a HS hub. Therefore, all port-level control performs through the hub class to the nearest hub. | FS and LS device can be downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, port-level control acts using the hub class through the nearest hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSC <sub>n</sub> . |

*Table continues on the next page...*

**Table 51-79. Functional Differences Between EHCI and EHCI with Embedded TT (continued)**

| Standard EHCI   | EHCI with embedded Transaction Translator   |
|---|---|
| FS and LS devices are assumed to be downstream from a HS hub with HubAddr equal to X. [where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to FS/LS (split target hub)] | FS and LS device can be downstream from a HS hub with HubAddr equal to X [HubAddr > 0] or directly attached [where HubAddr equals 0 and HubAddr is the address of the root hub where the bus transitions from HS to FS/LS (split target hub is the root hub)] |

### 51.5.5.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the root hub. It is demonstrated here how hub address and endpoint speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) – asynchronous (bulk/control endpoints) periodic (interrupt)
  - Hub address equals 0
  - Transactions to direct attached device/hub.
    - QH.EPS equals port speed
  - Transactions to a device downstream from direct attached FS hub.
    - QH.EPS equals downstream device speed

**Note**

When QH.EPS equals 01 (LS) and PORTSC<sub>n</sub>[PSPD] equals 00 (FS), a LS-pre-PID is sent before transmitting LS traffic.

Maximum packet size must equal 64 or less to prevent undefined behavior.

2. siTD (for direct attach FS) – Periodic (ISO endpoint)
  - All FS ISO transactions:
    - Hub address equals 0
    - siTD.EPS equals 00 (full speed)

Maximum packet size must equal to 1023 or less to prevent undefined behavior.

### 51.5.5.1.5 Operational Model

The operational models are well defined for the behavior of the transaction translator (see USB 2.0 specification) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded transaction translator exists within the USB host controller, no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections briefly discuss the operational model for how the EHCI and transaction translator operational models combine without the physical bus between. The following sections assume the reader is familiar with the EHCI and USB 2.0 transaction translator operational models.

#### 51.5.5.1.5.1 Microframe Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator uses the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic because they execute when possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer cannot babble through the SOF (start of B-frame 0.)

#### 51.5.5.1.5.2 Split State Machines

The start and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete-split operation is simple an internal operation to the embedded transaction translator. The next table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

**Table 51-80. Emulated Handshakes**

| Condition   | Emulate TT Response                |
|---|------------------------------------|
| <b>Start-Split:</b> All asynchronous buffers full           | NAK                                |
| <b>Start-Split:</b> All periodic buffers full               | ERR                                |
| <b>Start-Split:</b> Success for start of async. transaction | ACK                                |
| <b>Start-Split:</b> Start periodic transaction              | No handshake (Ok)                  |
| <b>Complete-Split:</b> Failed to find transaction in queue  | Bus time-out                       |
| <b>Complete-Split:</b> Transaction in queue is busy         | NYET                               |
| <b>Complete-Split:</b> Transaction in queue is complete     | Actual handshake from FS/LS device |

### 51.5.5.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- USB 2.0 – 11.17.3
  - Sequencing is provided and a packet length estimator ensures no full-/low-speed packet babbles into SOF time.
- USB 2.0 – 11.17.4
  - • Transaction tracking for 2 data pipes.
- USB 2.0 – 11.17.5
  - • Clear\_TT\_Buffer capability provided though the use of the TTCTRL register.

### 51.5.5.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded transaction translator:

- USB 2.0 – 11.18.6.[1-2]
  - Abort of pending start-splits
    - EOF (and not started in microframes 6)
    - Idle for more than 4 microframes
  - Abort of pending complete-splits

- EOF
- Idle for more than 4 microframes
- USB 2.0 - 11.18.[7-8]
  - Transaction tracking for up to four data pipes.
  - No more than 4 periodic transactions (interrupt/isochronous) can be scheduled through the embedded TT per frame.
- Complete-split transaction searching.

### Note

There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

## 51.5.5.2 Device Operation

The co-existence of a device operational controller within the USB OTG module has little effect on EHCI compatibility for host operation. However, given that the USB OTG controller initializes in neither host nor device mode, the USBMODE register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

## 51.5.5.3 Non-Zero Fields in the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational registers have use in device mode. Adhere to these steps:

- Write operations to all EHCI reserved fields (some of which are device fields in the USB OTG module) in the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the module must properly mask EHCI reserved fields (some of which are device fields in the USB OTG module registers).

#### 51.5.5.4 SOF Interrupt

The SOF interrupt is a free running 125  $\mu$ s or 1 ms interrupt for host mode. EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. The free running interrupt is shared with the device mode start-of-frame interrupt. See the sections for the USBSTS and USBINTR registers for more information.

#### 51.5.5.5 Embedded Design

This is an embedded USB host controller as defined by the EHCI specification; therefore, it does not implement the PCI configuration registers.

##### 51.5.5.5.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like those provided by the frame adjust register in the PCI configuration registers. Starts of microframes are timed precisely to 125  $\mu$ s using the transceiver clock as a reference clock or a 60 Mhz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces.

#### 51.5.5.6 Miscellaneous Variations from EHCI

##### 51.5.5.6.1 Programmable Physical Interface Behavior

The modules support multiple physical interfaces that can operate in different modes when the module is configured with the software programmable physical interface modes. The control bits for selecting the PHY operating mode are added to the PORTSC<sub>n</sub> register providing a capability not defined by the EHCI specification.

##### 51.5.5.6.2 Discovery

### 51.5.5.6.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the  $PORTSC_n$  register for a duration of 10 ms. Due to the complexity required to support the attachment of devices not high speed, a counter is present in the design that can count the 10 ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is summarized as:

- Port change interrupt—Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall set the  $PORTSC_n[PR]$  bit to reset the device.
- Software shall clear the  $PORTSC_n[PR]$  bit after 10 ms.
  - This step, necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a 0 to the reset bit while a reset is in progress, the write is ignored and the reset continues until completion.
- Port change interrupt—Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed is determined.

### 51.5.5.6.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which re-assigns the port owner for any device that does not connect at high speed, this host controller supports direct attach of non-HS devices. Therefore, the following differences are important regarding port speed detection:

- Port owner hand-off is not implemented. Therefore,  $PORTSC_n[PO]$  bit is read-only and always reads 0.
- A 2-bit port speed indicator field has been added to  $PORTSC_n$  to provide the current operating speed of the port to the host controller driver.
- A 1-bit high-speed indicator bit has been added to  $PORTSC_n$  to signify that the port is in HS vs. FS/LS.
  - This information is redundant with the 2-bit port speed indicator field above.

## Chapter 52

# CAN (FlexCAN)

### 52.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx) Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

**Figure 52-1. FlexCAN block diagram**

### 52.1.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the MCU.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames

- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

### 52.1.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation

- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version

### 52.1.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at MCU level and MCR[FRZ\_ACK ] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at MCU level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Stop mode](#) for more information.

## 52.2 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external MCU pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 52-1. FlexCAN signal descriptions**

| Signal | Description      | I/O    |
|--------|------------------|--------|
| CAN Rx | CAN Receive Pin  | Input  |
| CAN Tx | CAN Transmit Pin | Output |

### 52.2.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 52.2.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 52.3 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the MCU.

### 52.3.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 52-2](#).

**Table 52-2. Register access and reset information**

| Register                                     | Access type | Affected by hard reset | Affected by soft reset |
|--|-------------|------------------------|------------------------|
| Module Configuration Register (MCR)          | S           | Yes                    | Yes                    |
| Control 1 register (CTRL1)                   | S/U         | Yes                    | No                     |
| Free Running Timer register (TIMER)          | S/U         | Yes                    | Yes                    |
| Rx Mailboxes Global Mask register (RXMGMASK) | S/U         | No                     | No                     |
| Rx Buffer 14 Mask register (RX14MASK)        | S/U         | No                     | No                     |
| Rx Buffer 15 Mask register (RX15MASK)        | S/U         | No                     | No                     |
| Error Counter Register (ECR)                 | S/U         | Yes                    | Yes                    |
| Error and Status 1 Register (ESR1)           | S/U         | Yes                    | Yes                    |
| Interrupt Masks 1 register (IMASK1)          | S/U         | Yes                    | Yes                    |
| Interrupt Flags 1 register (IFLAG1)          | S/U         | Yes                    | Yes                    |
| Control 2 Register (CTRL2)                   | S/U         | Yes                    | No                     |
| Error and Status 2 Register (ESR2)           | S/U         | Yes                    | Yes                    |
| CRC Register (CRCR)                          | S/U         | Yes                    | Yes                    |
| Rx FIFO Global Mask register (RXFGMASK)      | S/U         | No                     | No                     |
| Rx FIFO Information Register (RXFIR)         | S/U         | No                     | No                     |
| Message buffers                              | S/U         | No                     | No                     |
| Rx Individual Mask Registers                 | S/U         | No                     | No                     |

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixteen 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x17F .

### CAN memory map

| Absolute address (hex) | Register name                                     | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|---|-----------------|--------|-------------|------------------------------|
| 4002_4000              | Module Configuration Register (CAN0_MCR)          | 32              | R/W    | D890_000Fh  | <a href="#">52.3.2/1623</a>  |

| 400A_48A8              | Rx Individual Mask Registers (CAN1_RXIMR10) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |
| 400A_48AC              | Rx Individual Mask Registers (CAN1_RXIMR11) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |
| 400A_48B0              | Rx Individual Mask Registers (CAN1_RXIMR12) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |
| 400A_48B4              | Rx Individual Mask Registers (CAN1_RXIMR13) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |
| 400A_48B8              | Rx Individual Mask Registers (CAN1_RXIMR14) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |
| 400A_48BC              | Rx Individual Mask Registers (CAN1_RXIMR15) | 32              | R/W    | Undefined   | <a href="#">52.3.17/1650</a> |

### 52.3.2 Module Configuration Register (CANx\_MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Address: Base address + 0h offset

**CANx\_MCR field descriptions**

| Field      | Description  |
|------------|--|
| 31<br>MDIS | <p>Module Disable</p> <p>This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This is the only bit within this register not affected by soft reset.</p> <p>0 Enable the FlexCAN module.<br/>1 Disable the FlexCAN module.</p> |
| 30<br>FRZ  | <p>Freeze Enable</p> <p>The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at MCU level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.</p>  |

Table continues on the next page...

### CANx\_MCR field descriptions (continued)

| Field         | Description  |
|---------------|--|
|               | <p>0 Not enabled to enter Freeze mode.</p> <p>1 Enabled to enter Freeze mode.</p>  |
| 29<br>RFEN    | <p>Rx FIFO Enable</p> <p>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Rx FIFO not enabled.</p> <p>1 Rx FIFO enabled.</p>  |
| 28<br>HALT    | <p>Halt FlexCAN</p> <p>Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode.</p> <p>0 No Freeze mode request.</p> <p>1 Enters Freeze mode if the FRZ bit is asserted.</p>  |
| 27<br>NOTRDY  | <p>FlexCAN Not Ready</p> <p>This read-only bit indicates that FlexCAN is either in Disable mode , Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes.</p> <p>0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode.</p> <p>1 FlexCAN module is either in Disable mode , Stop mode or Freeze mode.</p>   |
| 26<br>WAKMSK  | <p>Wake Up Interrupt Mask</p> <p>This bit enables the Wake Up Interrupt generation under Self Wake Up mechanism.</p> <p>0 Wake Up Interrupt is disabled.</p> <p>1 Wake Up Interrupt is enabled.</p>  |
| 25<br>SOFTRST | <p>Soft Reset</p> <p>When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers .</p> <p>The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at MCU level . Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.</p> <p>Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied.</p> <p>0 No reset request.</p> <p>1 Resets the registers affected by soft reset.</p> |

Table continues on the next page...

**CANx\_MCR field descriptions (continued)**

| Field        | Description  |
|--------------|--|
| 24<br>FRZACK | <p>Freeze Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode".</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN not in Freeze mode, prescaler running.<br/>1 FlexCAN in Freeze mode, prescaler stopped.</p> |
| 23<br>SUPV   | <p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only . This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses .<br/>1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location .</p>   |
| 22<br>SLFWAK | <p>Self Wake Up</p> <p>This bit enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wake up event, that is, a recessive-to-dominant transition.</p> <p>If a wake up event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks.</p> <p>When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware.</p> <p>0 FlexCAN Self Wake Up feature is disabled.<br/>1 FlexCAN Self Wake Up feature is enabled.</p>  |
| 21<br>WRNEN  | <p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.<br/>1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>   |
| 20<br>LPMACK | <p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode , Stop mode ). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode.</p>  |

Table continues on the next page...

### CANx\_MCR field descriptions (continued)

| Field          | Description  |
|----------------|--|
|                | <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN is not in a low-power mode.<br/>1 FlexCAN is in a low-power mode.</p>   |
| 19<br>WAKSRC   | <p>Wake Up Source</p> <p>This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wake up. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus.<br/>1 FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.</p>  |
| 18<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 17<br>SRXDIS   | <p>Self Reception Disable</p> <p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Self reception enabled.<br/>1 Self reception disabled.</p>  |
| 16<br>IRMQ     | <p>Individual Rx Masking And Queue Enable</p> <p>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.<br/>1 Individual Rx masking and queue feature are enabled.</p>   |
| 15<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 14<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 13<br>LPRIOEN  | <p>Local Priority Enable</p> <p>This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Local Priority disabled.<br/>1 Local Priority enabled.</p> |
| 12<br>AEN      | <p>Abort Enable</p> <p>This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so</p>   |

*Table continues on the next page...*

**CANx\_MCR field descriptions (continued)**

| Field             | Description   |
|-------------------|---|
|                   | <p>that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission.</p> <p><b>CAUTION:</b> Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted.</p> <p>0 Abort disabled.<br/>1 Abort enabled.</p>  |
| 11–10<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 9–8<br>IDAM       | <p>ID Acceptance Mode</p> <p>This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>00 Format A: One full ID (standard and extended) per ID Filter Table element.<br/>01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element.<br/>10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element.<br/>11 Format D: All frames rejected.</p>  |
| 7<br>Reserved     | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 6–0<br>MAXMB      | <p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1)</p> <p>Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").</p> |

### 52.3.3 Control 1 register (CANx\_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: Base address + 4h offset

|       |         |        |        |     |         |         |    |    |     |         |       |      |     |         |    |    |

#### CANx\_CTRL1 field descriptions

| Field            | Description   |
|------------------|---|
| 31–24<br>PRESDIV | <p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Sclock frequency = PE clock frequency / (PRESDIV + 1)</p> |
| 23–22<br>RJW     | <p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Resync Jump Width = RJW + 1.</p>   |
| 21–19<br>PSEG1   | <p>Phase Segment 1</p> <p>This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.</p>  |
| 18–16<br>PSEG2   | <p>Phase Segment 2</p>  |

Table continues on the next page...

**CANx\_CTRL1 field descriptions (continued)**

| Field         | Description   |
|---------------|---|
|               | <p>This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.</p>   |
| 15<br>BOFFMSK | <p>Bus Off Mask</p> <p>This bit provides a mask for the Bus Off Interrupt.</p> <p>0 Bus Off interrupt disabled.<br/>1 Bus Off interrupt enabled.</p>  |
| 14<br>ERRMSK  | <p>Error Mask</p> <p>This bit provides a mask for the Error Interrupt.</p> <p>0 Error interrupt disabled.<br/>1 Error interrupt enabled.</p>  |
| 13<br>CLKSRC  | <p>CAN Engine Clock Source</p> <p>This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclck). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Section "Protocol Timing".</p> <p>0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock.<br/>1 The CAN engine clock source is the peripheral clock.</p>   |
| 12<br>LPB     | <p>Loop Back Mode</p> <p>This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.</p> <p>0 Loop Back disabled.<br/>1 Loop Back enabled.</p> |
| 11<br>TWRNMSK | <p>Tx Warning Interrupt Mask</p> <p>This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Tx Warning Interrupt disabled.<br/>1 Tx Warning Interrupt enabled.</p>   |
| 10<br>RWRNMSK | <p>Rx Warning Interrupt Mask</p>  |

Table continues on the next page...

### CANx\_CTRL1 field descriptions (continued)

| Field           | Description  |
|-----------------|--|
|                 | <p>This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Rx Warning Interrupt disabled.<br/>1 Rx Warning Interrupt enabled.</p>   |
| 9–8<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>  |
| 7<br>SMP        | <p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Just one sample is used to determine the bit value.<br/>1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.</p>  |
| 6<br>BOFFREC    | <p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B.<br/>1 Automatic recovering from Bus Off state disabled.</p> |
| 5<br>TSYN       | <p>Timer Sync</p> <p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Timer Sync feature disabled<br/>1 Timer Sync feature enabled</p>  |
| 4<br>LBUF       | <p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Buffer with highest priority is transmitted first.<br/>1 Lowest number buffer is transmitted first.</p>  |
| 3<br>LOM        | <p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages</p>  |

| Field          | Description  |
|----------------|--|
|                | <p>acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message.</p> <p>Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCONF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Listen-Only mode is deactivated.<br/>1 FlexCAN module operates in Listen-Only mode.</p> |
| 2-0<br>PROPSEG | <p>Propagation Segment</p> <p>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0-7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Propagation Segment Time = (PROPSEG + 1) × Time-Quanta.</p> <p>Time-Quantum = one Sclock period.</p>   |

#### 52.3.4 Free Running Timer (CANx\_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

## 52.3.5 Rx Mailboxes Global Mask Register (CANx\_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 10h offset

See the description of the CAN_RXMGMASK register.</p> <p>0 The corresponding bit in the filter is "don't care."<br/>1 The corresponding bit in the filter is checked.</p> |

### 52.3.8 Error Counter (CANx\_ECR)

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect ‘Error Passive’ state.
- If the FlexCAN state is ‘Error Passive’, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect ‘Error Active’ state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect ‘Bus Off’ state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in ‘Bus Off’ state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be ‘Error Active’ and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to ‘Error Passive’ state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the ‘Bus Off’ state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to ‘Error Active’ state.

### 52.3.9 Error and Status 1 register (CANx\_ESR1)

This register reflects various error conditions, some general status of the device and it is the source of interrupts to the CPU.

The CPU read action clears bits 15-10. Therefore the reported error conditions (bits 15-10) are those that occurred since the last time the CPU read this register. Bits 9-3 are status bits.

The following table shows the FlexCAN state variables and their meanings. Other combinations not shown in the table are reserved.

| SYNCH | IDLE | TX | RX | FlexCAN State               |
|-------|------|----|----|-----------------------------|
| 0     | 0    | 0  | 0  | Not synchronized to CAN bus |
| 1     | 1    | x  | x  | Idle                        |
| 1     | 0    | 1  | 0  | Transmitting                |
| 1     | 0    | 0  | 1  | Receiving                   |

### CANx\_ESR1 field descriptions (continued)

| Field | Description   |
|-------|---|
|       | When a recessive-to-dominant transition is detected on the CAN bus and if the MCR[WAKMSK] bit is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1.<br><br>When MCR[SLFWAK] is negated, this flag is masked. The CPU must clear this flag before disabling the bit. Otherwise it will be set when the SLFWAK is set again. Writing 0 has no effect. |
| 0     | No such occurrence.   |
| 1     | Indicates a recessive to dominant transition was received on the CAN bus.   |

### 52.3.10 Interrupt Masks 1 register (CANx\_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Address: Base address + 28h offset

### CANx\_IMASK1 field descriptions

| Field         | Description  |
|---------------|--|
| 31–0<br>BUFLM | Buffer MB <sub>i</sub> Mask<br><br>Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0.<br><br><b>NOTE:</b> Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set.<br><br>0 The corresponding buffer Interrupt is disabled.<br>1 The corresponding buffer Interrupt is enabled. |

### 52.3.11 Interrupt Flags 1 register (CANx\_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: Base address + 30h offset

**CANx\_IFLAG1 field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–8<br>BUF31TO8I | <p>Buffer MB<sub>i</sub> Interrupt</p> <p>Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception.</p> <p>1 The corresponding buffer has successfully completed transmission or reception.</p> |

Table continues on the next page...

### CANx\_IFLAG1 field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 7<br>BUF7I      | <p>Buffer MB7 Interrupt Or "Rx FIFO Overflow"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF7I flag represents "Rx FIFO Overflow" when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox.</p> <p>0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1</p> <p>1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1</p>   |
| 6<br>BUF6I      | <p>Buffer MB6 Interrupt Or "Rx FIFO Warning"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF6I flag represents "Rx FIFO Warning" when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4.</p> <p>0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1</p> <p>1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1</p> |
| 5<br>BUF5I      | <p>Buffer MB5 Interrupt Or "Frames available in Rx FIFO"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF5I flag represents "Frames available in Rx FIFO" when MCR[RFEN] is set. In this case, the flag indicates that at least one frame is available to be read from the Rx FIFO.</p> <p>0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1</p> <p>1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1</p>  |
| 4-1<br>BUF4TO1I | <p>Buffer MB<sub>i</sub> Interrupt Or "reserved"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.</p> <p><b>NOTE:</b> These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes.</p> <p>The BUF4TO1I flags are reserved when MCR[RFEN] is set.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>   |
| 0<br>BUF0I      | <p>Buffer MB0 Interrupt Or "reserved"</p> <p>When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0.</p>  |

### CANx\_IFLAG1 field descriptions (continued)

| Field | Description   |
|-------|---|
|       | <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when MCR[RFEN] is set.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p> |

### 52.3.12 Control 2 register (CANx\_CTRL2)

This register contains control bits for CAN errors, FIFO features, and mode selection.

Address: Base address + 34h offset

|       |          |    |    |        |          |    |    |    |          |    |    |    |          |          |          |    |

### CANx\_CTRL2 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–29<br>Reserved | This field is reserved. This read-only field is reserved and always has the value 0.  |
| 28<br>WRMFRZ      | <p>Write-Access To Memory In Freeze Mode</p> <p>Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode.</p> <p>0 Maintain the write access restrictions.</p> <p>1 Enable unrestricted write access to FlexCAN memory.</p>  |
| 27–24<br>RFFN     | <p>Number Of Rx FIFO Filters</p> <p>This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the MCU. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB].</p> |

## CANx\_CTRL2 field descriptions (continued)

| Field     | Description  |
|-----------|--|
|           | <p>This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.</p> <p>The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.</p> <p>If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration.</p> <p>If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted.</p> <p>The optimal configuration for TASD can be calculated as:</p> $TASD = 25 - \left\{ f \times [MAXMB + 3 - \frac{CANCLK}{(RFEN \times 8) - (RFFN \times 2)}] \times 2 \right\} / \left\{ f \times [1 + \frac{SYS}{(PSEG1+1) + (PSEG2+1) + (PROPSEG+1)}] \times (PRES DIV+1) \right\}$ <p>where:</p> <ul style="list-style-type: none"> <li>• <math>f_{CANCLK}</math> is the Protocol Engine (PE) Clock (see section "Protocol Timing"), in Hz</li> <li>• <math>f_{SYS}</math> is the peripheral clock, in Hz</li> <li>• MAXMB is the value in CTRL1[MAXMB] field</li> <li>• RFEN is the value in CTRL1[RFEN] bit</li> <li>• RFFN is the value in CTRL2[RFFN] field</li> <li>• PSEG1 is the value in CTRL1[PSEG1] field</li> <li>• PSEG2 is the value in CTRL1[PSEG2] field</li> <li>• PROPSEG is the value in CTRL1[PROPSEG] field</li> <li>• PRES DIV is the value in CTRL1[PRES DIV] field</li> </ul> <p>See Section "Arbitration process" and Section "Protocol Timing" for more details.</p> <p><b>NOTE:</b> The recommended value for TASD is 22.</p> |
| 18<br>MRP | <p>Mailboxes Reception Priority</p> <p>If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Matching starts from Rx FIFO and continues on Mailboxes.<br/>1 Matching starts from Mailboxes and continues on Rx FIFO.</p>  |
| 17<br>RRS | <p>Remote Request Storing</p> <p>If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated.</p> <p>If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID.</p>   |

### CANx\_CTRL2 field descriptions (continued)

| Field            | Description   |
|------------------|---|
|                  | <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Remote Response Frame is generated.<br/>1 Remote Request Frame is stored.</p>   |
| 16<br>EACEN      | <p>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes</p> <p>This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.<br/>1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.</p> |
| 15-0<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER\_OF\_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

### 52.3.13 Error and Status 2 register (CANx\_ESR2)

This register reflects various interrupt flags and some general status.

Address: Base address + 38h offset

### CANx\_ESR2 field descriptions

| Field             | Description   |
|-------------------|---|
| 31-23<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 22-16<br>LPTM     | <p>Lowest Priority Tx Mailbox</p> <p>If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM</p> |

Table continues on the next page...

### CANx\_ESR2 field descriptions (continued)

| Field            | Description   |
|------------------|---|
|                  | calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.   |
| 15<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 14<br>VPS        | <p>Valid Priority Status</p> <p>This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.</p> <p><b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.</p> <p>0 Contents of IMB and LPTM are invalid.<br/>1 Contents of IMB and LPTM are valid.</p> |
| 13<br>IMB        | <p>Inactive Mailbox</p> <p>If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:</p> <ul style="list-style-type: none"> <li>• During arbitration, if an LPTM is found and it is inactive.</li> <li>• If IMB is not asserted and a frame is transmitted successfully.</li> </ul> <p>This bit is cleared in all start of arbitration (see Section "Arbitration process").</p> <p><b>NOTE:</b> LPTM mechanism have the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM].</p> <p>0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox.<br/>1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.</p>                                 |
| 12–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 52.3.14 CRC Register (CANx\_CRCR)

This register provides information about the CRC of transmitted messages.

Address: Base address + 44h offset

|       |            |       |    |    |    |    |    |    |       |    |    |    |    |    |    |    |

| W     | [Reserved] |       |    |    |    |    |    |    |       |    |    |    |    |    |    |    |
| Reset | 0          | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

#### CANx\_CRCR field descriptions

| Field             | Description  |
|-------------------|--|
| 31–23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 22–16<br>MBCRC    | CRC Mailbox<br>This field indicates the number of the Mailbox corresponding to the value in TXCRC field.   |
| 15<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 14–0<br>TXCRC     | CRC Transmitted<br>This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted. |

### 52.3.15 Rx FIFO Global Mask register (CANx\_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 48h offset

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

### 52.3.16 Rx FIFO Information Register (CANx\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: Base address + 4Ch offset

|       |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| W     | [Shaded] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | x*       | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x*    | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### CANx\_RXFIR field descriptions

| Field            | Description   |
|------------------|---|
| 31–9<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 8–0<br>IDHIT     | Identifier Acceptance Filter Hit Indicator<br><br>This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted. |

### 52.3.17 Rx Individual Mask Registers (CANx\_RXIMRn)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset + (4d × i), where i=0d to 15d

\* Notes:

- x = Undefined at reset.

### CANx\_RXIMRn field descriptions

| Field            | Description   |
|------------------|---|
| 31–0<br>MI[31:0] | Individual Mask Bits<br><br>Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. |

**CANx\_RXIMRn field descriptions (continued)**

| Field | Description   |
|-------|---|
|       | For Mailbox filters, see the RXMGMASK register description.<br>For Rx FIFO ID Filter Table elements, see the RXFGMASK register description. |
| 0     | The corresponding bit in the filter is "don't care."  |
| 1     | The corresponding bit in the filter is checked.   |

### 52.3.50 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x17F is used by the mailboxes.

**Table 52-102. Message buffer structure**

|     | 31          | 30 | 29 | 28 | 27                          | 24 | 23  | 22  | 21          | 20  | 19            | 18 | 17 | 16         | 15 | 8 | 7 | 0 |  |
|-----|-------------|----|----|----|-----------------------------|----|-----|-----|-------------|-----|---------------|----|----|------------|----|---|---|---|--|

#### CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 52-103](#) and [Table 52-104](#). See [Functional description](#) for additional information.

**Table 52-103. Message buffer code for Rx buffers**

| CODE description                        | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment  |
|---|----------------------------------|------------------|---|------------------|--|
| 0b0000: INACTIVE<br>— MB is not active. | INACTIVE                         | —                | —   | —                | MB does not participate in the matching process. |

*Table continues on the next page...*

**Table 52-103. Message buffer code for Rx buffers (continued)**

| CODE description                        | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment   |
|---|----------------------------------|------------------|---|------------------|---|
| 0b0100: EMPTY — MB is active and empty. | EMPTY                            | —                | FULL  | —                | When a frame is received successfully (after the <a href="#">Move-in</a> process), the CODE field is automatically updated to FULL.   |
| 0b0010: FULL — MB is full.              | FULL                             | Yes              | FULL  | —                | The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See <a href="#">Matching process</a> for matching details related to FULL code. |
|   |                                  | No               | OVERRUN   | —                | If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.  |

Table continues on the next page...

**Table 52-103. Message buffer code for Rx buffers (continued)**

| CODE description   | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment   |
|--|----------------------------------|------------------|---|------------------|---|
| 0b0110: OVERRUN — MB is being overwritten into a full buffer.  | OVERRUN                          | Yes              | FULL  | —                | If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.   |
|  |                                  | No               | OVERRUN   | —                | If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.  |
| 0b1010: RANSWER <sup>4</sup> — A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return. | RANSWER                          | —                | TANSWER(0b1110)                                 | 0                | A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See <a href="#">Matching process</a> for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received. |
|  |                                  | —                | —   | 1                | This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.   |

Table continues on the next page...

**Table 52-103. Message buffer code for Rx buffers (continued)**

| CODE description  | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment   |
|---|----------------------------------|------------------|---|------------------|---|
| CODE[0]=1b1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB. | BUSY <sup>5</sup>                | —                | FULL  | —                | Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE. |
|   |                                  | —                | OVERRUN   | —                |   |

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 52-104. Message buffer code for Tx buffers**

| CODE Description  | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment   |
|---|-------------------------|--------|---------------------------------------|---|
| 0b1000: INACTIVE — MB is not active                                 | INACTIVE                | —      | —                                     | MB does not participate in arbitration process.   |
| 0b1001: ABORT — MB is aborted                                       | ABORT                   | —      | —                                     | MB does not participate in arbitration process.   |
| 0b1100: DATA — MB is a Tx Data Frame (MB RTR must be 0)             | DATA                    | 0      | INACTIVE                              | Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.                     |
| 0b1100: REMOTE — MB is a Tx Remote Request Frame (MB RTR must be 1) | REMOTE                  | 1      | EMPTY                                 | Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID. |

Table continues on the next page...

**Table 52-104. Message buffer code for Tx buffers (continued)**

| CODE Description  | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment  |
|---|-------------------------|--------|---------------------------------------|--|
| 0b1110: TANSWER — MB is a Tx Response Frame from an incoming Remote Request Frame | TANSWER                 | —      | RANSWER                               | This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details. |

### **SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

### **IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

### **RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 52-103](#), [Table 52-104](#), and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

#### **DLC** — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the [Table 52-102](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 52-105](#)).

#### **TIME STAMP** — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

#### **PRIO** — Local priority

This 3-bit field is used only when LPRIO\_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

#### **ID** — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

#### **DATA BYTE 0–7** — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

**Table 52-105. DATA BYTEs validity**

| DLC | Valid DATA BYTEs |
|-----|------------------|
| 0   | none             |
| 1   | DATA BYTE 0      |
| 2   | DATA BYTE 0–1    |
| 3   | DATA BYTE 0–2    |
| 4   | DATA BYTE 0–3    |
| 5   | DATA BYTE 0–4    |
| 6   | DATA BYTE 0–5    |
| 7   | DATA BYTE 0–6    |
| 8   | DATA BYTE 0–7    |

### 52.3.51 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 52-106. Rx FIFO structure**

|                    | 31          | 28 | 24 | 23 | 22          | 21  | 20  | 19  | 18 | 17 | 16          | 15         | 8           | 7 | 0 |  |
|--------------------|-------------|----|----|----|-------------|-----|-----|-----|----|----|-------------|------------|-------------|---|---|--|
| 0x80               |             |    |    |    | SRR         | IDE | RTR | DLC |    |    |             | TIME STAMP |             |   |   |  |
| 0x84               |             |    |    |    | ID standard |     |     |     |    |    | ID extended |            |             |   |   |  |
| 0x88               | Data byte 0 |    |    |    | Data byte 1 |     |     |     |    |    | Data byte 2 |            | Data byte 3 |   |   |  |
| 0x8C               | Data byte 4 |    |    |    | Data byte 5 |     |     |     |    |    | Data byte 6 |            | Data byte 7 |   |   |  |
| 0x90<br>to<br>0xDC | Reserved    |    |    |    |             |     |     |     |    |    |             |            |             |   |   |  |

Table continues on the next page...

**Table 52-106. Rx FIFO structure (continued)**

|                     |                                   |
|---------------------|-----------------------------------|
| 0xE0                | ID filter table element 0         |
| 0xE4                | ID filter table element 1         |
| 0xE8<br>to<br>0x2D4 | ID filter table elements 2 to 125 |
| 0x2D8               | ID filter table element 126       |
| 0x2DC               | ID filter table element 127       |
|                     | = Unimplemented or reserved       |

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

**Table 52-107. ID table structure**

| Format | 31                           | 30  | 29  | 24                           | 23 | 16 | 15                          | 14  | 13  | 8                          | 7 | 1 | 0 |  |
|--------|------------------------------|-----|---|------------------------------|----|----|-----------------------------|-----|---|----------------------------|---|---|---|--|
| A      | RTR                          | IDE | RXIDA<br>(standard = 29–19, extended = 29–1)    |                              |    |    |                             |     |   |                            |   |   |   |  |
| B      | RTR                          | IDE | RXIDB_0<br>(standard = 29–19, extended = 29–16) |                              |    |    | RTR                         | IDE | RXIDB_1<br>(standard = 13–3, extended = 13–0) |                            |   |   |   |  |
| C      | RXIDC_0<br>(std/ext = 31–24) |     |   | RXIDC_1<br>(std/ext = 23–16) |    |    | RXIDC_2<br>(std/ext = 15–8) |     |   | RXIDC_3<br>(std/ext = 7–0) |   |   |   |  |
|        | = Unimplemented or Reserved  |     |   |                              |    |    |                             |     |   |                            |   |   |   |  |

**RTR** — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

**IDE** — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

### **RXIDA** — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

### **RXIDB\_0, RXIDB\_1** — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

### **RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

## **52.4 Functional description**

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 52-103](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 52-104](#)).

## 52.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 52-103](#) and [Table 52-104](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

## 52.4.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

### 52.4.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

## 52.4.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

### 52.4.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 52-108. Composition of the arbitration value when Local Priority is disabled**

| Format             | Mailbox Arbitration Value (32 bits) |             |             |                             |             |
|--------------------|-------------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | Standard ID (11 bits)               | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits)        | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

### 52.4.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 52-109. Composition of the arbitration value when Local Priority is enabled**

| Format             | Mailbox Arbitration Value (35 bits) |                              |             |             |                             |             |
|--------------------|-------------------------------------|------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | PRI0 (3 bits)                       | Standard ID (11 bits)        | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | PRI0 (3 bits)                       | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 52.4.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. T ASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. T ASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
  - If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 52.4.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 52-103](#) and [Table 52-104](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 52-103](#). If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### CAUTION

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

#### 52.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame

- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 52-110. Matching architecture**

| Structure         | SMB[RTR] | CTRL2[RRS] | CTRL2[EAC EN] | MB[IDE]          | MB[RTR]             | MB[ID <sup>1</sup> ] | MB[CODE]                 |
|-------------------|----------|------------|---------------|------------------|---------------------|----------------------|--------------------------|
| Mailbox           | 0        | -          | 0             | cmp <sup>2</sup> | no_cmp <sup>3</sup> | cmp_msk <sup>4</sup> | EMPTY or FULL or OVERRUN |
| Mailbox           | 0        | -          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 0          | -             | cmp              | no_cmp              | cmp                  | RANSWER                  |
| Mailbox           | 1        | 1          | 0             | cmp              | no_cmp              | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 1          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| FIFO <sup>5</sup> | -        | -          | -             | cmp_msk          | cmp_msk             | cmp_msk              | -                        |

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no\_cmp: The SMB contents are not compared with the MB contents
4. cmp\_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY

## functional description

- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
  - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 52-111. Matching possibilities and resulting reception structures**

| RFEN   | IRMQ | MRP            | Matched in MB     | Matched in FIFO      | Reception structure | Description                             |
|--|------|----------------|-------------------|----------------------|---------------------|---|
| <b>No FIFO, only MB, match is always MB first</b>                  |      |                |                   |                      |                     |   |
| 0  | 0    | X <sup>1</sup> | None <sup>2</sup> | - <sup>3</sup>       | None                | Frame lost by no match                  |
| 0  | 0    | X              | Free <sup>4</sup> | -                    | FirstMB             |   |
| 0  | 1    | X              | None              | -                    | None                | Frame lost by no match                  |
| 0  | 1    | X              | Free              | -                    | FirstMb             |   |
| 0  | 1    | X              | NotFree           | -                    | LastMB              | Overrun                                 |
| <b>FIFO enabled, no match in FIFO is as if FIFO does not exist</b> |      |                |                   |                      |                     |   |
| 1  | 0    | X              | None              | None <sup>5</sup>    | None                | Frame lost by no match                  |
| 1  | 0    | X              | Free              | None                 | FirstMB             |   |
| 1  | 1    | X              | None              | None                 | None                | Frame lost by no match                  |
| 1  | 1    | X              | Free              | None                 | FirstMb             |   |
| 1  | 1    | X              | NotFree           | None                 | LastMB              | Overrun                                 |
| <b>FIFO enabled, Queue disabled</b>                                |      |                |                   |                      |                     |   |
| 1  | 0    | 0              | X                 | NotFull <sup>6</sup> | FIFO                |   |
| 1  | 0    | 0              | None              | Full <sup>7</sup>    | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1  | 0    | 0              | Free              | Full                 | FirstMB             |   |
| 1  | 0    | 0              | NotFree           | Full                 | FirstMB             |   |
| 1  | 0    | 1              | None              | NotFull              | FIFO                |   |
| 1  | 0    | 1              | None              | Full                 | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1  | 0    | 1              | Free              | X                    | FirstMB             |   |
| 1  | 0    | 1              | NotFree           | X                    | FirtsMb             | Overrun                                 |
| <b>FIFO enabled, Queue enabled</b>                                 |      |                |                   |                      |                     |   |
| 1  | 1    | 0              | X                 | NotFull              | FIFO                |   |
| 1  | 1    | 0              | None              | Full                 | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1  | 1    | 0              | Free              | Full                 | FirstMB             |   |
| 1  | 1    | 0              | NotFree           | Full                 | LastMb              | Overrun                                 |
| 1  | 1    | 1              | None              | NotFull              | FIFO                |   |
| 1  | 1    | 1              | Free              | X                    | FirstMB             |   |
| 1  | 1    | 1              | NotFree           | NotFull              | FIFO                |   |
| 1  | 1    | 1              | NotFree           | Full                 | LastMb              | Overrun                                 |

1. This is a don't care condition.

2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).

## functional description

3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXGMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

## 52.4.5 Move process

There are two types of move process: move-in and move-out.

### 52.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

### 52.4.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

### 52.4.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

### 52.4.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.

- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

### 52.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see [Transmission abort mechanism](#))

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

#### NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by

FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

### 52.4.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

#### NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

## Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)) and it will take place only when the module resumes to Normal or Freeze modes.

### 52.4.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

## 52.4.8 CAN protocol related features

This section describes the CAN protocol related features.

### 52.4.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 52.4.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

### 52.4.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

### 52.4.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

**Figure 52-98. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The oscillator clock has better jitter performance.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments<sup>2</sup> (see [Figure 52-99](#) and [Table 52-112](#)):

- SYNC\_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

$$\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}$$

---

2. For further explanation of the underlying concepts, see ISO/DIS 11519-1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

**Figure 52-99. Segments within the bit time**

Whenever CAN bit is used as a measure of duration (for example, MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- $f_{CANCLK}$  is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- $f_{SYS}$  is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;
- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRES DIV is the value in CTRL1[PRES DIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

**Table 52-112. Time segment syntax**

| Syntax         | Description  |
|----------------|--|
| SYNC_SEG       | System expects transitions to occur on the bus during this period.   |
| Transmit Point | A node in transmit mode transfers a new value to the CAN bus at this point.  |
| Sample Point   | A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample. |

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

**Table 52-113. Bosch CAN 2.0B standard compliant bit time segment settings**

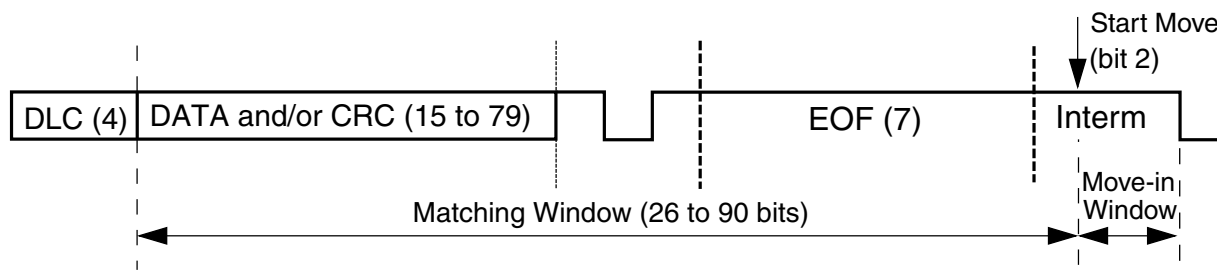

| Time segment 1 | Time segment 2 | Re-synchronization jump width |
|----------------|----------------|-------------------------------|
| 5 .. 10        | 2              | 1 .. 2                        |
| 4 .. 11        | 3              | 1 .. 3                        |
| 5 .. 12        | 4              | 1 .. 4                        |
| 6 .. 13        | 5              | 1 .. 4                        |
| 7 .. 14        | 6              | 1 .. 4                        |
| 8 .. 15        | 7              | 1 .. 4                        |
| 9 .. 16        | 8              | 1 .. 4                        |

**Note**

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1). For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

**52.4.8.5 Arbitration and matching timing**

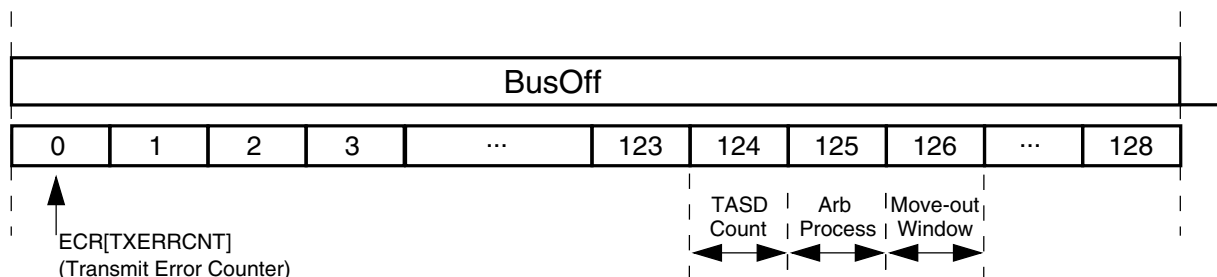

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 52-100. Matching and move-in time windows**

**Figure 52-101. Arbitration and move-out time windows**

**Figure 52-102. Arbitration at the end of bus off and move-out time windows**

**NOTE**

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 52-113](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, see [Clock domains and restrictions](#)
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

**Table 52-114. Minimum ratio between peripheral clock frequency and CAN bit rate**

| Number of Message Buffers | RFEN | Minimum number of peripheral clocks per CAN bit |
|---------------------------|------|---|
| 16 and 32                 | 0    | 16  |
| 64                        | 0    | 25  |
| 16                        | 1    | 16  |
| 32                        | 1    | 17  |

*Table continues on the next page...*

**Table 52-114. Minimum ratio between peripheral clock frequency and CAN bit rate (continued)**

| Number of Message Buffers | RFEN | Minimum number of peripheral clocks per CAN bit |
|---------------------------|------|---|
| 64                        | 1    | 30  |

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRES DIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRES DIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

### 52.4.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

#### NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

### 52.4.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

#### CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

#### 52.4.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the MCU is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode. The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities

- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ\_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK\_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The MCU is removed from Debug Mode and/or the HALT bit is negated

The FRZ\_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

### 52.4.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM\_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM\_ACK bit and negates the FRZ\_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM\_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

### 52.4.10.3 Stop mode

This is a system low-power mode in which all MCU clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request. This can be as a result of the Self Wake mechanism.

In the Self Wake mechanism, if the SLFWAK bit in MCR Register was set at the time FlexCAN entered Stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAKINT bit in the ESR Register and, if enabled by the WAKMSK bit in MCR, generates a Wake Up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request.

FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wake-up from Stop mode. Note that wake-up from Stop mode only works when both bits are asserted.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

**Table 52-115. Wake-up from Stop Mode**

| SLFWAK | WAKINT | WAKMSK | MCU<br>clocks enabled | Wake-up interrupt<br>generated |
|--------|--------|--------|-----------------------|--------------------------------|
| 0      | -      | -      | No                    | No                             |
| 0      | -      | -      | No                    | No                             |
| 1      | 0      | 0      | No                    | No                             |
| 1      | 0      | 1      | No                    | No                             |
| 1      | 1      | 0      | No                    | No                             |
| 1      | 1      | 1      | Yes                   | Yes                            |

### 52.4.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, Wake Up, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

#### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled ( $MCR[RFEN] = 1$ ), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag," and bits 4-0 are unused. See the description of IFLAG1 for more information.

For a combined interrupt where multiple MB interrupt sources are ORed together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Wake Up, Tx Warning, and Rx Warning generate interrupts like the MB interrupt sources, and they can be read from ESR1 and ESR2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in CTRL1; the Wake-Up interrupt mask bit is located in MCR.

## 52.4.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF.

From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

## 52.5 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

### 52.5.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- MCU level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 52-2](#) to see what registers are affected by soft reset.
- MCU level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is unsynchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see [Freeze mode](#). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register

- Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
- Enable the warning interrupts by setting the WRNEN bit
- If required, disable frame self reception by setting the SRXDIS bit
- Enable the Rx FIFO by setting the RFEN bit
- Enable the abort mechanism by setting the AEN bit
- Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Determine the bit rate by programming the PRES DIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts), in MCR Register for Wake-Up interrupt and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

## Chapter 53

# Serial Peripheral Interface (SPI)

### 53.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device.

#### 53.1.1 Block Diagram

The block diagram of this module is as follows:

Figure 53-1. SPI Block Diagram

### 53.1.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- Asynchronous clocking scheme for Register and Protocol Interfaces

- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - two transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 16 bits
    - SPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
- 6 peripheral chip selects (PCSEs), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSEs) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:

- Support for Stop mode
- Support for Doze mode

### 53.1.3 Interface configurations

#### 53.1.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

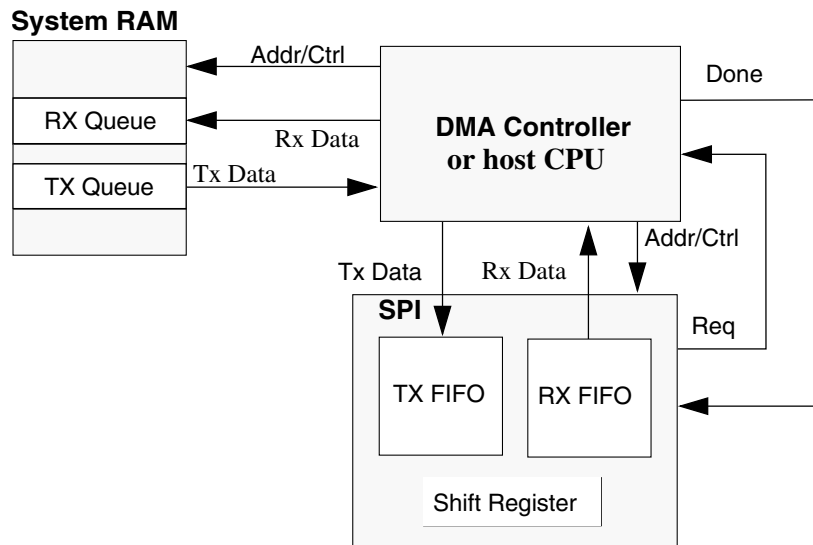

Figure 53-2. SPI with queues and DMA

#### 53.1.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:

- Master mode
- Slave mode
- Module Disable mode
- MCU-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The MCU-specific modes are controlled by signals external to the module. The MCU-specific modes are modes that an MCU may enter in parallel to the block-specific modes.

#### 53.1.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- SOUT
- PCS[x]

#### 53.1.4.2 Slave Mode

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{SS}$  signals are configured as inputs and driven by an SPI bus master.

#### 53.1.4.3 Module Disable Mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

### 53.1.4.4 External Stop Mode

External Stop mode is used for MCU power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

### 53.1.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the MCU is in debug mode.
- If the bit is cleared, the MCU debug mode has no effect on the module.

## 53.2 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

**Table 53-1. Module signal descriptions**

| Signal                  | Master mode   | Slave mode       | I/O |
|-------------------------|---|------------------|-----|
| PCS0/ $\overline{SS}$   | Peripheral Chip Select 0 (O)                            | Slave Select (I) | I/O |
| PCS[1:3]                | Peripheral Chip Selects 1–3                             | (Unused)         | O   |
| PCS4                    | Peripheral Chip Select 4                                |                  | O   |
| PCS5/ $\overline{PCSS}$ | Peripheral Chip Select 5 /Peripheral Chip Select Strobe | (Unused)         | O   |
| SCK                     | Serial Clock (O)  | Serial Clock (I) | I/O |
| SIN                     | Serial Data In  | Serial Data In   | I   |
| SOUT                    | Serial Data Out   | Serial Data Out  | O   |

### 53.2.1 PCS0/ $\overline{SS}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

### 53.2.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 53.2.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 53.2.4 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

### 53.2.5 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

### 53.2.6 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

### NOTE

Serial Data Out output buffers are controlled through SIU (or SIUL) and cannot be controlled through the module.

## 53.2.7 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

### NOTE

Serial Data Out output buffers are controlled through SIU (or SIUL) and cannot be controlled through the module.

## 53.3 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the POPR and RXFRn also results in a transfer error.

**SPI memory map**

| Absolute address (hex) | Register name   | Width (in bits) | Access | Reset value                 | Section/page                 |
|------------------------|---|-----------------|--------|-----------------------------|------------------------------|
| 4002_C000              | Module Configuration Register (SPI0_MCR)                                  | 32              | R/W    | 0000_0001h                  | <a href="#">53.3.1/1703</a>  |

### 53.3.1 Module Configuration Register (SPIx\_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: Base address + 0h offset

### 53.3.2 Transfer Count Register (SPIx\_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

### SPIx\_TCR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>SPI_TCNT | <p>SPI Transfer Counter</p> <p>Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.</p> |
| 15–0<br>Reserved  | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>  |

### 53.3.3 Clock and Transfer Attributes Register (In Master Mode) (SPIx\_CTARn)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Address: Base address + Ch offset + (4d × i), where i=0d to 1d

| <b>Table 53-38. Baud Rate Scaler (continued)</b> |                        |
| CTARn[BR]  | Baud Rate Scaler Value |
| 1000   | 256                    |
| 1001   | 512                    |
| 1010   | 1024                   |
| 1011   | 2048                   |
| 1100   | 4096                   |
| 1101   | 8192                   |
| 1110   | 16384                  |
| 1111   | 32768                  |

**53.3.4 Clock and Transfer Attributes Register (In Slave Mode) (SPIx\_CTARn\_SLAVE)**

When the module is configured as an SPI bus slave, the CTAR0 register is used.

Address: Base address + Ch offset + (0d × i), where i=0d to 0d

**SPIx\_CTARn\_SLAVE field descriptions**

| Field          | Description  |
|----------------|--|
| 31<br>Reserved | Always write the reset value to this field.<br><br>This field is reserved. |
| 30–27<br>FMSZ  | Frame Size   |

*Table continues on the next page...*

### SPIx\_CTARn\_SLAVE field descriptions (continued)

| Field             | Description  |
|-------------------|--|
|                   | The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.  |
| 26<br>CPOL        | <p>Clock Polarity</p> <p>Selects the inactive state of the Serial Communications Clock (SCK).</p> <p><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</p> <p>0 The inactive state value of SCK is low.<br/>1 The inactive state value of SCK is high.</p>   |
| 25<br>CPHA        | <p>Clock Phase</p> <p>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</p> <p>0 Data is captured on the leading edge of SCK and changed on the following edge.<br/>1 Data is changed on the leading edge of SCK and captured on the following edge.</p> |
| 24–23<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>   |
| 22<br>Reserved    | This field is reserved.  |
| 21–0<br>Reserved  | This field is reserved.  |

### 53.3.5 Status Register (SPIx\_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: Base address + 2Ch offset

### 53.3.7 PUSH TX FIFO Register In Master Mode (SPIx\_PUSHR)

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access transfers all 32 bits to the TX FIFO. In Master mode, the register transfers 16 bits of data and 16 bits of command information. In Slave mode, all 32 bits can be used as data, supporting up to 32-bit frame operation.

A read access of PUSHR returns the topmost TX FIFO entry.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: Base address + 34h offset

**SPIx\_PUSHR field descriptions**

| Field             | Description  |
|-------------------|--|

### 53.3.8 PUSH TX FIFO Register In Slave Mode (SPIx\_PUSHR\_SLAVE)

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access to PUSHR transfers all 32 bits to the TX FIFO.

In master mode, the register transfers 16 bits of data and 16 bits of command information to the TX FIFO. In slave mode, all 32 register bits can be used as data, supporting up to 32-bit SPI Frame operation.

Address: Base address + 34h offset

#### SPIx\_PUSHR\_SLAVE field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>TXDATA | Transmit Data<br><br>Holds SPI data to be transferred according to the associated SPI command. |

### 53.3.9 POP RX FIFO Register (SPIx\_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: Base address + 38h offset

#### SPIx\_POPR field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>RXDATA | Received Data<br><br>Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points. |

### 53.3.10 Transmit FIFO Registers (SPIx\_TXFRn)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO.

Address: Base address + 3Ch offset + (4d × i), where i=0d to 3d

#### SPIx\_TXFRn field descriptions

| Field                     | Description  |
|---------------------------|--|
| 31–16<br>TXCMD_<br>TXDATA | Transmit Command or Transmit Data<br><br>In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, the TXDATA contains 16 MSB bits of the SPI data to be shifted out. |
| 15–0<br>TXDATA            | Transmit Data<br><br>Contains the SPI data to be shifted out.  |

### 53.3.11 Receive FIFO Registers (SPIx\_RXFRn)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO.

Address: Base address + 7Ch offset + (4d × i), where i=0d to 3d

#### SPIx\_RXFRn field descriptions

| Field          | Description   |
|----------------|---|
| 31–0<br>RXDATA | Receive Data<br><br>Contains the received SPI data. |

| Field | Description |
|-------|-------------|
|-------|-------------|

## 53.4 Functional description

The module supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx\_MCR is 0b00.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See [Clock and Transfer Attributes Register \(In Master Mode\) \(SPI\\_CTARn\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

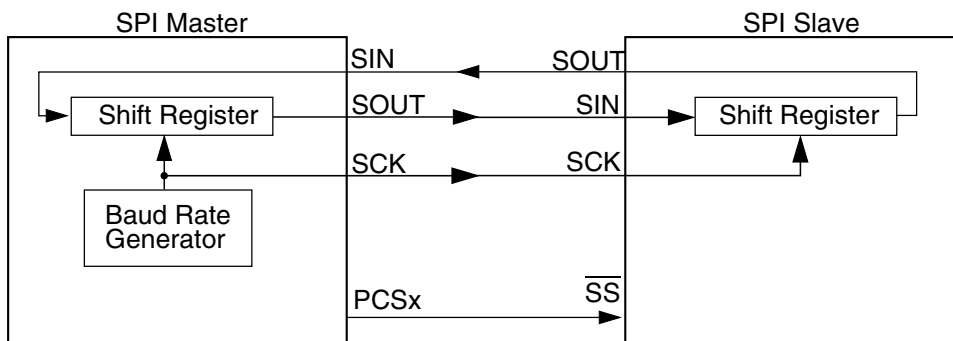

Figure 53-91. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip configuration details for the number of PCS signals used in this MCU.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

### 53.4.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

## 53.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

### 53.4.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(SPI\\_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

### 53.4.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

### 53.4.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS\_TXF] bit disables the TX FIFO, and setting the MCR[DIS\_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO is disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

### 53.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

#### 53.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller

indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

#### 53.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR\_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

#### 53.4.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

### 53.4.2.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

### 53.4.2.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX\_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

## 53.4.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

**Figure 53-92. Communications clock prescalers and scalers**

### 53.4.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

**Table 53-130. Baud rate computation example**

| $f_p$   | PBR  | Prescaler | BR     | Scaler | DBR | Baud rate |
|---------|------|-----------|--------|--------|-----|-----------|
| 100 MHz | 0b00 | 2         | 0b0000 | 2      | 0   | 25 Mb/s   |
| 20 MHz  | 0b00 | 2         | 0b0000 | 2      | 1   | 10 Mb/s   |

#### NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 53.4.3.2 PCS to SCK Delay ( $t_{csc}$ )

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 53-94](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR<sub>x</sub> registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

**Table 53-131. PCS to SCK delay computation example**

| $f_{sys}$ | PCSSCK | Prescaler | CSSCK  | Scaler | PCS to SCK Delay |
|-----------|--------|-----------|--------|--------|------------------|
| 100 MHz   | 0b01   | 3         | 0b0100 | 32     | 0.96 $\mu$ s     |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 53.4.3.3 After SCK Delay ( $t_{ASC}$ )

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 53-94](#) and [Figure 53-95](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR $x$  registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

**Table 53-132. After SCK Delay computation example**

| $f_p$   | PASC | Prescaler | ASC    | Scaler | After SCK Delay |
|---------|------|-----------|--------|--------|-----------------|
| 100 MHz | 0b01 | 3         | 0b0100 | 32     | 0.96 $\mu$ s    |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 53.4.3.4 Delay after Transfer ( $t_{DT}$ )

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 53-94](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR $x$  registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

**Table 53-133. Delay after Transfer computation example**

| $f_p$   | PDT  | Prescaler | DT     | Scaler | Delay after Transfer |
|---------|------|-----------|--------|--------|----------------------|
| 100 MHz | 0b01 | 3         | 0b1110 | 32768  | 0.98 ms              |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the  $t_{DT}$  delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

### 53.4.3.5 Peripheral Chip Select Strobe Enable ( $\overline{\text{PCSS}}$ )

The  $\overline{\text{PCSS}}$  signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR,  $\overline{\text{PCSS}}$  provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the  $\overline{\text{PCSS}}$  signal relative to PCS signals.

**Figure 53-93. Peripheral Chip Select Strobe timing**

The delay between the assertion of the PCS signals and the assertion of  $\overline{\text{PCSS}}$  is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between  $\overline{\text{PCSS}}$  negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the  $t_{\text{pcssck}}$  delay.

**Table 53-134. Peripheral Chip Select Strobe Assert computation example**

| $f_{\text{P}}$ | PCSSCK | Prescaler | Delay before Transfer |
|----------------|--------|-----------|-----------------------|
| 100 MHz        | 0b11   | 7         | 70.0 ns               |

The following table shows an example of how to compute the  $t_{\text{pasc}}$  delay.

**Table 53-135. Peripheral Chip Select Strobe Negate computation example**

| $f_{\text{P}}$ | PASC | Prescaler | Delay after Transfer |
|----------------|------|-----------|----------------------|
| 100 MHz        | 0b11 | 7         | 70.0 ns              |

The  $\overline{\text{PCSS}}$  signal is not supported when Continuous Serial Communication SCK mode is enabled.

**NOTE**

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

**53.4.4 Transfer formats**

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

### 53.4.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

**Figure 53-94. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)**

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the  $t_{ASC}$  delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signals. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 53.4.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

**Figure 53-95. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)**

The master initiates the transfer by asserting the PCS signal to the slave. After the  $t_{CSC}$  delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signal. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 53.4.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI\_MCR[SMPL\_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL\_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- $T_{csc}$  - PCS to SCK assertion delay
- $T_{acs}$  - After SCK PCS negation delay
- $T_{su_{ms}}$  - master SIN setup time
- $T_{hd_{ms}}$  - master SIN hold time
- $T_{vd_{sl}}$  - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$  - data setup time on slave data input
- $T_{hd_{sl}}$  - data hold time on slave data input
- $T_{sys}$  - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and  $F_{sys}/F_{sck} = 4$ . Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

### Note

In the following diagrams,  $f_{sys}$  represents the protocol clock frequency from which the Baud frequency  $f_{sck}$  is derived.

**Figure 53-96. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/4$ )**

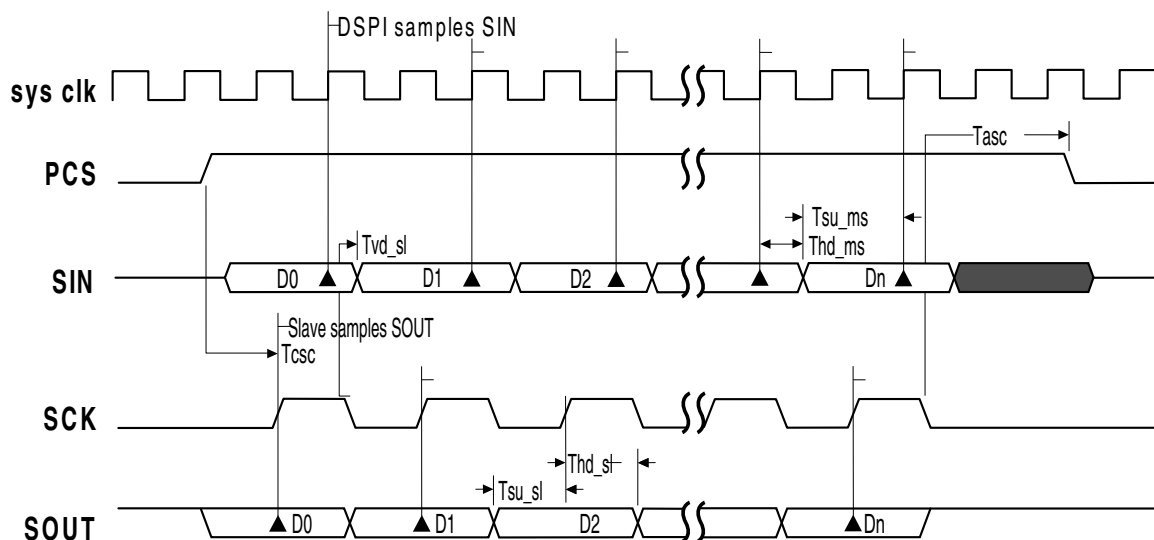

Figure 53-97. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/2$ )

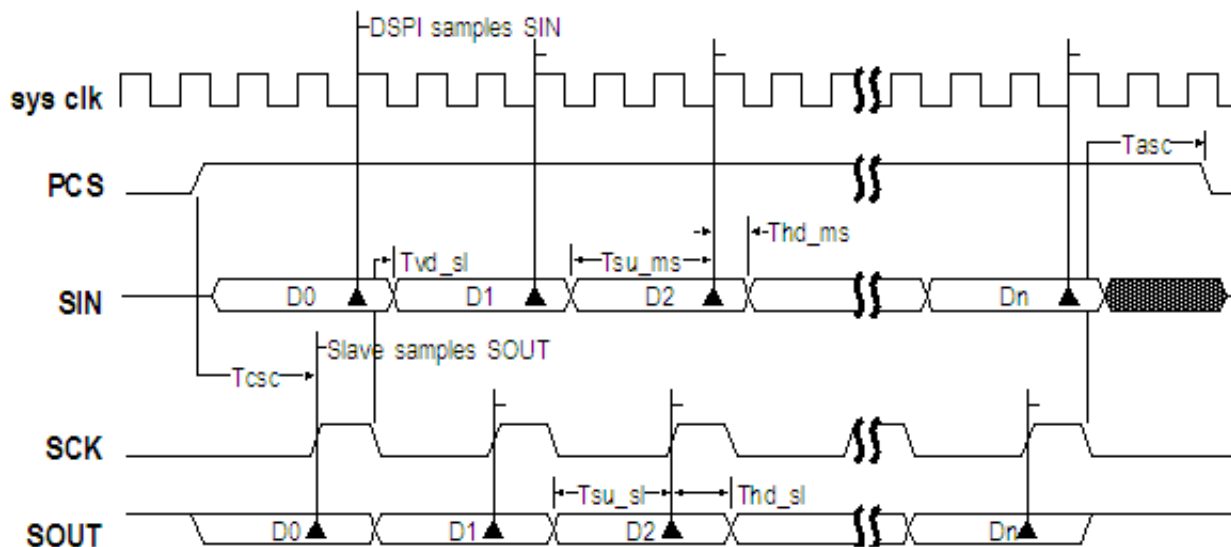

Figure 53-98. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/3$ )

#### 53.4.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT

signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

Figure 53-99. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/2$ )

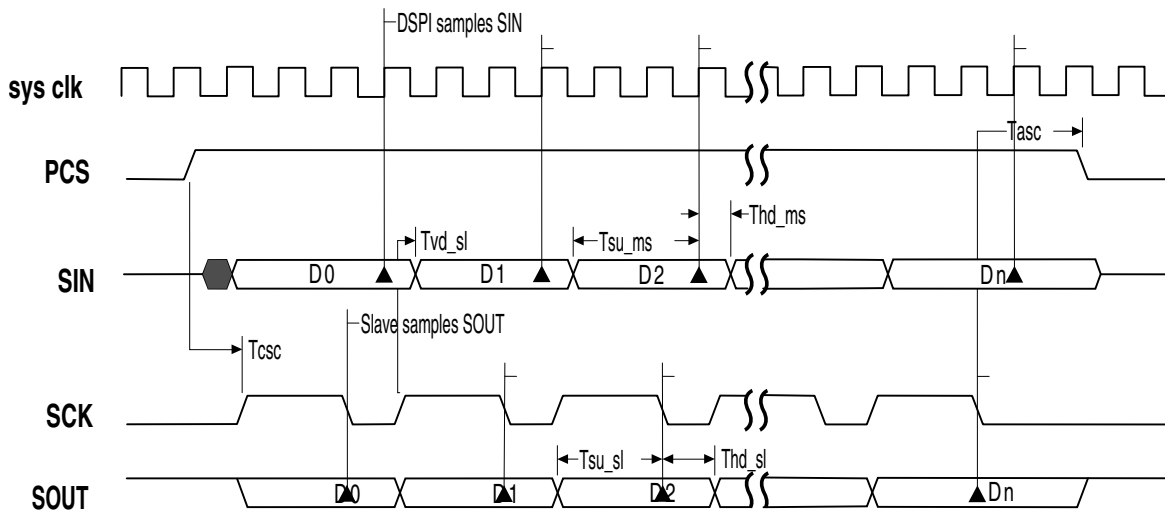

Figure 53-100. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/3$ )

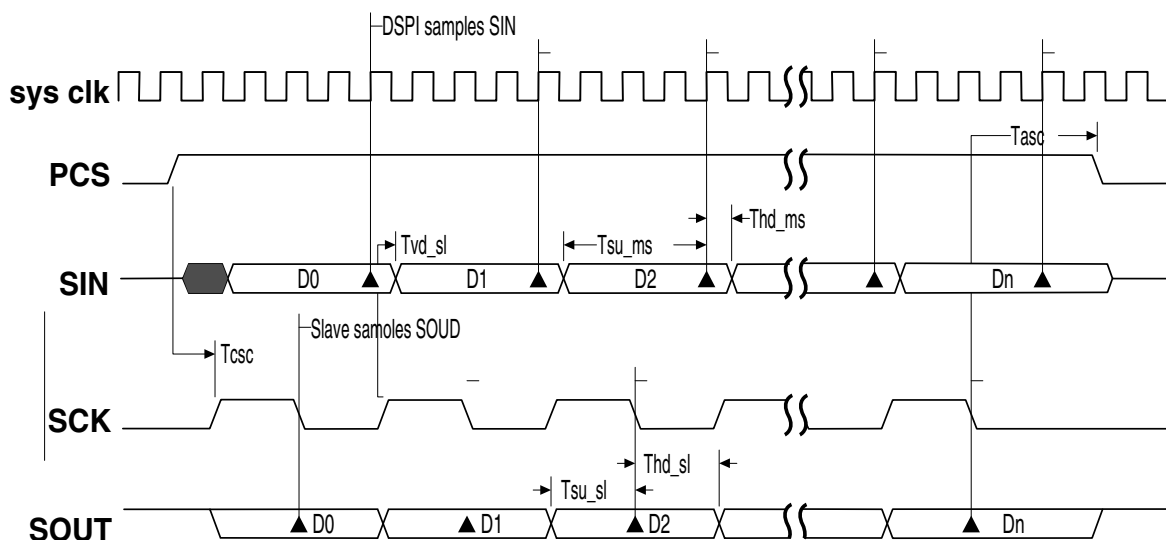

Figure 53-101. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/4$ )

### 53.4.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

**Figure 53-102. Example of non-continuous format (CPHA=1, CONT=0)**

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers ( $t_{DT}$ ) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

**Figure 53-103. Example of continuous transfer (CPHA=1, CONT=1)**

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX\_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

### NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

## 53.4.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT\_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT\_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer ( $t_{DT}$ ) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

### NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR\_TXF] field before initiating transfer.

**Figure 53-104. Continuous SCK Timing Diagram (CONT=0)**

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

**Figure 53-105. Continuous SCK timing diagram (CONT=1)**

### 53.4.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the  $\overline{SS}$  signal is asserted and any time when transmit data is ready and  $\overline{SS}$  signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the  $\overline{SS}$  negates before that last SCK edge, the data from shift register is lost.

### 53.4.7 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

**Table 53-136. Interrupt and DMA request conditions**

| Condition          | Flag | Interrupt | DMA |
|--------------------|------|-----------|-----|
| End of Queue (EOQ) | EOQF | Yes       | -   |
| TX FIFO Fill       | TFFF | Yes       | Yes |
| Transfer Complete  | TCF  | Yes       | -   |
| TX FIFO Underflow  | TFUF | Yes       | -   |

*Table continues on the next page...*

**Table 53-136. Interrupt and DMA request conditions (continued)**

| Condition        | Flag | Interrupt | DMA |
|------------------|------|-----------|-----|
| RX FIFO Drain    | RFDF | Yes       | Yes |
| RX FIFO Overflow | RFOF | Yes       | -   |

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

### 53.4.7.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF\_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

### 53.4.7.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF\_RE bit in the RSER is set. The TFFF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

#### NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

### 53.4.7.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF\_RE bit is set in the RSER.

### 53.4.7.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration . The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF\_RE bit in the RSER is set, an interrupt request is generated.

### 53.4.7.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF\_RE bit in the RSER is set. The RFDF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

### 53.4.7.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF\_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

## 53.4.8 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

### 53.4.8.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

### 53.4.8.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS\_TXF and DIS\_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

## 53.5 Initialization/application information

This section describes how to initialize the module.

### 53.5.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO by writing a 1 to the CLR\_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR\_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI\_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

### 53.5.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR\_TXF and CLR\_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

### 53.5.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

### 53.5.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

**Table 53-137. Baud rate values (bps)**

|                         |       | Baud rate divider prescaler values |       |       |       |
|-------------------------|-------|------------------------------------|-------|-------|-------|
|                         |       | 2                                  | 3     | 5     | 7     |
| Baud Rate Scaler Values | 2     | 25.0M                              | 16.7M | 10.0M | 7.14M |
|                         | 4     | 12.5M                              | 8.33M | 5.00M | 3.57M |
|                         | 6     | 8.33M                              | 5.56M | 3.33M | 2.38M |
|                         | 8     | 6.25M                              | 4.17M | 2.50M | 1.79M |
|                         | 16    | 3.12M                              | 2.08M | 1.25M | 893k  |
|                         | 32    | 1.56M                              | 1.04M | 625k  | 446k  |
|                         | 64    | 781k                               | 521k  | 312k  | 223k  |
|                         | 128   | 391k                               | 260k  | 156k  | 112k  |
|                         | 256   | 195k                               | 130k  | 78.1k | 55.8k |
|                         | 512   | 97.7k                              | 65.1k | 39.1k | 27.9k |
|                         | 1024  | 48.8k                              | 32.6k | 19.5k | 14.0k |
|                         | 2048  | 24.4k                              | 16.3k | 9.77k | 6.98k |
|                         | 4096  | 12.2k                              | 8.14k | 4.88k | 3.49k |
|                         | 8192  | 6.10k                              | 4.07k | 2.44k | 1.74k |
|                         | 16384 | 3.05k                              | 2.04k | 1.22k | 872   |
| 32768                   | 1.53k | 1.02k                              | 610   | 436   |       |

### 53.5.5 Delay settings

The following table shows the values for the Delay after Transfer ( $t_{DT}$ ) and CS to SCK Delay ( $T_{CSC}$ ) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 53-138. Delay values**

|                     |       | Delay prescaler values |               |               |               |
|---------------------|-------|------------------------|---------------|---------------|---------------|
|                     |       | 1                      | 3             | 5             | 7             |
| Delay scaler values | 2     | 20.0 ns                | 60.0 ns       | 100.0 ns      | 140.0 ns      |
|                     | 4     | 40.0 ns                | 120.0 ns      | 200.0 ns      | 280.0 ns      |
|                     | 8     | 80.0 ns                | 240.0 ns      | 400.0 ns      | 560.0 ns      |
|                     | 16    | 160.0 ns               | 480.0 ns      | 800.0 ns      | 1.1 $\mu$ s   |
|                     | 32    | 320.0 ns               | 960.0 ns      | 1.6 $\mu$ s   | 2.2 $\mu$ s   |
|                     | 64    | 640.0 ns               | 1.9 $\mu$ s   | 3.2 $\mu$ s   | 4.5 $\mu$ s   |
|                     | 128   | 1.3 $\mu$ s            | 3.8 $\mu$ s   | 6.4 $\mu$ s   | 9.0 $\mu$ s   |
|                     | 256   | 2.6 $\mu$ s            | 7.7 $\mu$ s   | 12.8 $\mu$ s  | 17.9 $\mu$ s  |
|                     | 512   | 5.1 $\mu$ s            | 15.4 $\mu$ s  | 25.6 $\mu$ s  | 35.8 $\mu$ s  |
|                     | 1024  | 10.2 $\mu$ s           | 30.7 $\mu$ s  | 51.2 $\mu$ s  | 71.7 $\mu$ s  |
|                     | 2048  | 20.5 $\mu$ s           | 61.4 $\mu$ s  | 102.4 $\mu$ s | 143.4 $\mu$ s |
|                     | 4096  | 41.0 $\mu$ s           | 122.9 $\mu$ s | 204.8 $\mu$ s | 286.7 $\mu$ s |
|                     | 8192  | 81.9 $\mu$ s           | 245.8 $\mu$ s | 409.6 $\mu$ s | 573.4 $\mu$ s |
|                     | 16384 | 163.8 $\mu$ s          | 491.5 $\mu$ s | 819.2 $\mu$ s | 1.1 ms        |
|                     | 32768 | 327.7 $\mu$ s          | 983.0 $\mu$ s | 1.6 ms        | 2.3 ms        |
|                     | 65536 | 655.4 $\mu$ s          | 2.0 ms        | 3.3 ms        | 4.6 ms        |

### 53.5.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX

FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 53-106. TX FIFO pointers and counter

### 53.5.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

### 53.5.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNEXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNEXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNEXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

# Chapter 54

## Inter-Integrated Circuit (I2C)

### 54.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The inter-integrated circuit (I<sup>2</sup>C, I2C, or IIC) module provides a method of communication between a number of devices.

The interface is designed to operate up to 100 kbit/s with maximum bus loading and timing. The I2C device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF. The I2C module also complies with the *System Management Bus (SMBus) Specification, version 2*.

#### 54.1.1 Features

The I2C module has the following features:

- Compatible with *The I<sup>2</sup>C-Bus Specification*
- Multimaster operation
- Software programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- START and STOP signal generation and detection
- Repeated START signal generation and detection
- Acknowledge bit generation and detection

- Bus busy detection
- General call recognition
- 10-bit address extension
- Support for *System Management Bus (SMBus) Specification, version 2*
- Programmable input glitch filter
- Low power mode wakeup on slave address match
- Range slave address support
- DMA support

### 54.1.2 Modes of operation

The I2C module's operation in various low power modes is as follows:

- Run mode: This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode: The module continues to operate when the core is in Wait mode and can provide a wakeup interrupt.
- Stop mode: The module is inactive in Stop mode for reduced power consumption, except that address matching is enabled in Stop mode. The STOP instruction does not affect the I2C module's register states.

### 54.1.3 Block diagram

The following figure is a functional block diagram of the I2C module.

Figure 54-1. I2C Functional block diagram

## 54.2 I<sup>2</sup>C signal descriptions

The signal properties of I<sup>2</sup>C are shown in the table found here.

Table 54-1. I<sup>2</sup>C signal descriptions

| Signal | Description   | I/O |
|--------|---|-----|
| SCL    | Bidirectional serial clock line of the I <sup>2</sup> C system. | I/O |
| SDA    | Bidirectional serial data line of the I <sup>2</sup> C system.  | I/O |

## 54.3 Memory map/register definition

This section describes in detail all I2C registers accessible to the end user.

### I2C memory map

| Absolute address (hex) | Register name  | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|--|-----------------|--------|-------------|------------------------------|
| 4006_6000              | I2C Address Register 1 (I2C0_A1)                         | 8               | R/W    | 00h         | <a href="#">54.3.1/1755</a>  |
| 4006_6001              | I2C Frequency Divider register (I2C0_F)                  | 8               | R/W    | 00h         | <a href="#">54.3.2/1755</a>  |
| 4006_6002              | I2C Control Register 1 (I2C0_C1)                         | 8               | R/W    | 00h         | <a href="#">54.3.3/1756</a>  |
| 4006_6003              | I2C Status register (I2C0_S)                             | 8               | R/W    | 80h         | <a href="#">54.3.4/1758</a>  |

### 54.3.1 I2C Address Register 1 (I2Cx\_A1)

This register contains the slave address to be used by the I2C module.

Address: Base address + 0h offset

|       |         |   |   |   |   |   |   |   |
|-------|---------|---|---|---|---|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | AD[7:1] |   |   |   |   |   |   | 0 |
| Write |         |   |   |   |   |   |   |   |
| Reset | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### I2Cx\_A1 field descriptions

| Field          | Description   |
|----------------|---|
| 7-1<br>AD[7:1] | Address<br>Contains the primary slave address used by the I2C module when it is addressed as a slave. This field is used in the 7-bit address scheme and the lower seven bits in the 10-bit address scheme. |
| 0<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 54.3.2 I2C Frequency Divider register (I2Cx\_F)

Address: Base address + 1h offset

|       |      |   |     |   |   |   |   |   |
|-------|------|---|-----|---|---|---|---|---|
| Bit   | 7    | 6 | 5   | 4 | 3 | 2 | 1 | 0 |
| Read  | MULT |   | ICR |   |   |   |   |   |
| Write |      |   |     |   |   |   |   |   |
| Reset | 0    | 0 | 0   | 0 | 0 | 0 | 0 | 0 |

#### I2Cx\_F field descriptions

| Field       | Description  |
|-------------|--|
| 7-6<br>MULT | Multiplier Factor<br>Defines the multiplier factor (mul). This factor is used along with the SCL divider to generate the I2C baud rate.<br><br>00 mul = 1<br>01 mul = 2<br>10 mul = 4<br>11 Reserved   |
| 5-0<br>ICR  | ClockRate<br>Prescales the I2C module clock for bit rate selection. This field and the MULT field determine the I2C baud rate, the SDA hold time, the SCL start hold time, and the SCL stop hold time. For a list of values corresponding to each ICR setting, see <a href="#">I2C divider and hold values</a> .<br>The SCL divider multiplied by multiplier factor (mul) determines the I2C baud rate.<br><br>I2C baud rate = I2C module clock speed (Hz) / (mul × SCL divider) |

### 54.3.3 I2C Control Register 1 (I2Cx\_C1)

Address: Base address + 2h offset

| Bit   | 7     | 6     | 5   | 4  | 3    | 2    | 1    | 0     |
|-------|-------|-------|-----|----|------|------|------|-------|
| Read  | IICEN | IICIE | MST | TX | TXAK | 0    | WUEN | DMAEN |
| Write |       |       |     |    |      | RSTA |      |       |
| Reset | 0     | 0     | 0   | 0  | 0    | 0    | 0    | 0     |

#### I2Cx\_C1 field descriptions

| Field      | Description  |
|------------|--|
| 7<br>IICEN | <p>I2C Enable</p> <p>Enables I2C module operation.</p> <p>0 Disabled<br/>1 Enabled</p> |
| 6<br>IICIE | <p>I2C Interrupt Enable</p> <p>Enables I2C interrupt requests.</p>                     |

Table continues on the next page...

I2Cx\_C1 field descriptions (continued)

| Field      | Description  |
|------------|--|
|            | 0 Disabled<br>1 Enabled  |
| 5<br>MST   | Master Mode Select<br><br>When MST is changed from 0 to 1, a START signal is generated on the bus and master mode is selected. When this bit changes from 1 to 0, a STOP signal is generated and the mode of operation changes from master to slave.<br><br>0 Slave mode<br>1 Master mode  |
| 4<br>TX    | Transmit Mode Select<br><br>Selects the direction of master and slave transfers. In master mode this bit must be set according to the type of transfer required. Therefore, for address cycles, this bit is always set. When addressed as a slave this bit must be set by software according to the SRW bit in the status register.<br><br>0 Receive<br>1 Transmit   |
| 3<br>TXAK  | Transmit Acknowledge Enable<br><br>Specifies the value driven onto the SDA during data acknowledge cycles for both master and slave receivers. The value of SMB[FAACK] affects NACK/ACK generation.<br><br><b>NOTE:</b> SCL is held low until TXAK is written.<br><br>0 An acknowledge signal is sent to the bus on the following receiving byte (if FAACK is cleared) or the current receiving byte (if FAACK is set).<br>1 No acknowledge signal is sent to the bus on the following receiving data byte (if FAACK is cleared) or the current receiving data byte (if FAACK is set). |
| 2<br>RSTA  | Repeat START<br><br>Writing 1 to this bit generates a repeated START condition provided it is the current master. This bit will always be read as 0. Attempting a repeat at the wrong time results in loss of arbitration.   |
| 1<br>WUEN  | Wakeup Enable<br><br>The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs.<br><br>0 Normal operation. No interrupt generated when address matching in low power mode.<br>1 Enables the wakeup function in low power mode.   |
| 0<br>DMAEN | DMA Enable<br><br>Enables or disables the DMA function.<br><br>0 All DMA signalling disabled.<br>1 DMA transfer is enabled. While SMB[FAACK] = 0, the following conditions trigger the DMA request: <ul style="list-style-type: none"> <li>• a data byte is received, and either address or data is transmitted. (ACK/NACK is automatic)</li> <li>• the first byte received matches the A1 register or is a general call address.</li> </ul>   |

Table continues on the next page...

### I2Cx\_C1 field descriptions (continued)

| Field | Description   |
|-------|---|
|       | <p>If any address matching occurs, S[IAAS] and S[TCF] are set. If the direction of transfer is known from master to slave, then it is not required to check S[SRW]. With this assumption, DMA can also be used in this case. In other cases, if the master reads data from the slave, then it is required to rewrite the C1 register operation. With this assumption, DMA cannot be used.</p> <p>When FACK = 1, an address or a data byte is transmitted.</p> |

### 54.3.4 I2C Status register (I2Cx\_S)

Address: Base address + 3h offset

| Bit   | 7   | 6    | 5    | 4    | 3   | 2   | 1     | 0    |
|-------|-----|------|------|------|-----|-----|-------|------|
| Read  | TCF | IAAS | BUSY | ARBL | RAM | SRW | IICIF | RXAK |
| Write |     |      |      | w1c  |     |     | w1c   |      |
| Reset | 1   | 0    | 0    | 0    | 0   | 0   | 0     | 0    |

#### I2Cx\_S field descriptions

| Field     | Description   |
|-----------|---|
| 7<br>TCF  | <p>Transfer Complete Flag</p> <p>Acknowledges a byte transfer; TCF is set on the completion of a byte transfer. This bit is valid only during or immediately following a transfer to or from the I2C module. TCF is cleared by reading the I2C data register in receive mode or by writing to the I2C data register in transmit mode.</p> <p>0 Transfer in progress<br/>1 Transfer complete</p>   |
| 6<br>IAAS | <p>Addressed As A Slave</p> <p>This bit is set by one of the following conditions:</p> <ul style="list-style-type: none"> <li>The calling address matches the programmed primary slave address in the A1 register, or matches the range address in the RA register (which must be set to a nonzero value and under the condition I2C_C2[RMEN] = 1).</li> <li>C2[GCAEN] is set and a general call is received.</li> <li>SMB[SIICAEN] is set and the calling address matches the second programmed slave address.</li> <li>ALERTEN is set and an SMBus alert response address is received</li> <li>RMEN is set and an address is received that is within the range between the values of the A1 and RA registers.</li> </ul> <p>IAAS sets before the ACK bit. The CPU must check the SRW bit and set TX/RX accordingly. Writing the C1 register with any value clears this bit.</p> <p>0 Not addressed<br/>1 Addressed as a slave</p> |
| 5<br>BUSY | <p>Bus Busy</p> <p>Indicates the status of the bus regardless of slave or master mode. This bit is set when a START signal is detected and cleared when a STOP signal is detected.</p>  |

Table continues on the next page...

**I2Cx\_S field descriptions (continued)**

| Field      | Description  |
|------------|--|
|            | 0 Bus is idle<br>1 Bus is busy   |
| 4<br>ARBL  | Arbitration Lost<br><br>This bit is set by hardware when the arbitration procedure is lost. The ARBL bit must be cleared by software, by writing 1 to it.<br><br>0 Standard bus operation.<br>1 Loss of arbitration.   |
| 3<br>RAM   | Range Address Match<br><br>This bit is set to 1 by any of the following conditions, if I2C_C2[RMEN] = 1: <ul style="list-style-type: none"> <li>Any nonzero calling address is received that matches the address in the RA register.</li> <li>The calling address is within the range of values of the A1 and RA registers.</li> </ul> <b>NOTE:</b> For the RAM bit to be set to 1 correctly, C1[IICIE] must be set to 1.<br><br>Writing the C1 register with any value clears this bit to 0.<br><br>0 Not addressed<br>1 Addressed as a slave   |
| 2<br>SRW   | Slave Read/Write<br><br>When addressed as a slave, SRW indicates the value of the R/ $\bar{W}$ command bit of the calling address sent to the master.<br><br>0 Slave receive, master writing to slave<br>1 Slave transmit, master reading from slave   |
| 1<br>IICIF | Interrupt Flag<br><br>This bit sets when an interrupt is pending. This bit must be cleared by software by writing 1 to it, such as in the interrupt routine. One of the following events can set this bit: <ul style="list-style-type: none"> <li>One byte transfer, including ACK/NACK bit, completes if FACK is 0. An ACK or NACK is sent on the bus by writing 0 or 1 to TXAK after this bit is set in receive mode.</li> <li>One byte transfer, excluding ACK/NACK bit, completes if FACK is 1.</li> <li>Match of slave address to calling address including primary slave address, range slave address, alert response address, second slave address, or general call address.</li> <li>Arbitration lost</li> <li>In SMBus mode, any timeouts except SCL and SDA high timeouts</li> </ul> 0 No interrupt pending<br>1 Interrupt pending |
| 0<br>RXAK  | Receive Acknowledge<br><br>0 Acknowledge signal was received after the completion of one byte of data transmission on the bus<br>1 No acknowledge signal detected  |

### 54.3.5 I2C Data I/O register (I2Cx\_D)

Address: Base address + 4h offset

#### I2Cx\_D field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>DATA | <p>Data</p> <p>In master transmit mode, when data is written to this register, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data.</p> <p><b>NOTE:</b> When making the transition out of master receive mode, switch the I2C mode before reading the Data register to prevent an inadvertent initiation of a master receive data transfer.</p> <p>In slave mode, the same functions are available after an address match occurs.</p> <p>The C1[TX] bit must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For example, if the I2C module is configured for master transmit but a master receive is desired, reading the Data register does not initiate the receive.</p> <p>Reading the Data register returns the last byte received while the I2C module is configured in master receive or slave receive mode. The Data register does not reflect every byte that is transmitted on the I2C bus, and neither can software verify that a byte has been written to the Data register correctly by reading it back.</p> <p>In master transmit mode, the first byte of data written to the Data register following assertion of MST (start bit) or assertion of RSTA (repeated start bit) is used for the address transfer and must consist of the calling address (in bits 7-1) concatenated with the required R/W bit (in position bit 0).</p> |

### 54.3.6 I2C Control Register 2 (I2Cx\_C2)

Address: Base address + 5h offset

#### I2Cx\_C2 field descriptions

| Field      | Description  |
|------------|--|
| 7<br>GCAEN | <p>General Call Address Enable</p> <p>Enables general call address.</p> <p>0 Disabled</p> <p>1 Enabled</p> |

Table continues on the next page...

**I2Cx\_C2 field descriptions (continued)**

| Field           | Description  |
|-----------------|--|
| 6<br>ADEXT      | Address Extension<br>Controls the number of bits used for the slave address.<br>0 7-bit address scheme<br>1 10-bit address scheme  |
| 5<br>HDRS       | High Drive Select<br>Controls the drive capability of the I2C pads.<br>0 Normal drive mode<br>1 High drive mode  |
| 4<br>SBRC       | Slave Baud Rate Control<br>Enables independent slave mode baud rate at maximum frequency, which forces clock stretching on SCL in very fast I2C modes. To a slave, an example of a "very fast" mode is when the master transfers at 40 kbit/s but the slave can capture the master's data at only 10 kbit/s.<br>0 The slave baud rate follows the master baud rate and clock stretching may occur<br>1 Slave baud rate is independent of the master baud rate  |
| 3<br>RMEN       | Range Address Matching Enable<br>This bit controls the slave address matching for addresses between the values of the A1 and RA registers. When this bit is set, a slave address matching occurs for any address greater than the value of the A1 register and less than or equal to the value of the RA register.<br>0 Range mode disabled. No address matching occurs for an address within the range of values of the A1 and RA registers.<br>1 Range mode enabled. Address matching occurs when a slave receives an address within the range of values of the A1 and RA registers. |
| 2-0<br>AD[10:8] | Slave Address<br>Contains the upper three bits of the slave address in the 10-bit address scheme. This field is valid only while the ADEXT bit is set.   |

**54.3.7 I2C Programmable Input Glitch Filter Register (I2Cx\_FLT)**

Address: Base address + 6h offset

### 54.3.8 I2C Range Address register (I2Cx\_RA)

Address: Base address + 7h offset

#### I2Cx\_RA field descriptions

| Field         | Description   |
|---------------|---|
| 7–1<br>RAD    | Range Slave Address<br><br>This field contains the slave address to be used by the I2C module. The field is used in the 7-bit address scheme. If I2C_C2[RMEN] is set to 1, any nonzero value write enables this register. This register value can be considered as a maximum boundary in the range matching mode. |
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 54.3.9 I2C SMBus Control and Status register (I2Cx\_SMB)

#### NOTE

When the SCL and SDA signals are held high for a length of time greater than the high timeout period, the SHTF1 flag sets. Before reaching this threshold, while the system is detecting how long these signals are being held high, a master assumes that the bus is free. However, the SHTF1 bit is set to 1 in the bus transmission process with the idle bus state.

#### NOTE

When the TCKSEL bit is set, there is no need to monitor the SHTF1 bit because the bus speed is too high to match the protocol of SMBus.

Address: Base address + 8h offset

| 7-0<br>SSLT[7:0] | SSLT[7:0]<br>Least significant byte of SCL low timeout value that determines the timeout period of SCL low. |

## 54.4 Functional description

This section provides a comprehensive functional description of the I2C module.

### 54.4.1 I2C protocol

The I2C bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfers.

All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors depends on the system.

Normally, a standard instance of communication is composed of four parts:

1. START signal
2. Slave address transmission
3. Data transfer
4. STOP signal

The STOP signal should not be confused with the CPU STOP instruction. The following figure illustrates I2C bus system communication.

**Figure 54-38. I2C bus transmission signals**

### 54.4.1.1 START signal

The bus is free when no master device is engaging the bus (both SCL and SDA are high). When the bus is free, a master may initiate communication by sending a START signal. A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer—each data transfer might contain several bytes of data—and brings all slaves out of their idle states.

### 54.4.1.2 Slave address transmission

Immediately after the START signal, the first byte of a data transfer is the slave address transmitted by the master. This address is a 7-bit calling address followed by an  $R/\bar{W}$  bit. The  $R/\bar{W}$  bit tells the slave the desired direction of data transfer.

- 1 = Read transfer: The slave transmits data to the master
- 0 = Write transfer: The master transmits data to the slave

Only the slave with a calling address that matches the one transmitted by the master responds by sending an acknowledge bit. The slave sends the acknowledge bit by pulling SDA low at the ninth clock.

No two slaves in the system can have the same address. If the I2C module is the master, it must not transmit an address that is equal to its own slave address. The I2C module cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the I2C module reverts to slave mode and operates correctly even if it is being addressed by another master.

### 54.4.1.3 Data transfers

When successful slave addressing is achieved, data transfer can proceed on a byte-by-byte basis in the direction specified by the  $\overline{R/W}$  bit sent by the calling master.

All transfers that follow an address cycle are referred to as data transfers, even if they carry subaddress information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low. Data must be held stable while SCL is high. There is one clock pulse on SCL for each data bit, and the MSB is transferred first. Each data byte is followed by a ninth (acknowledge) bit, which is signaled from the receiving device by pulling SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master in the ninth bit, the slave must leave SDA high. The master interprets the failed acknowledgement as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets it as an end to data transfer and releases the SDA line.

In the case of a failed acknowledgement by either the slave or master, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a STOP signal.
- Commences a new call by generating a repeated START signal.

### 54.4.1.4 STOP signal

The master can terminate the communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is asserted.

The master can generate a STOP signal even if the slave has generated an acknowledgement, at which point the slave must release the bus.

### 54.4.1.5 Repeated START signal

The master may generate a START signal followed by a calling command without generating a STOP signal first. This action is called a repeated START. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

### 54.4.1.6 Arbitration procedure

The I2C bus is a true multimaster bus that allows more than one master to be connected on it.

If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. The bus clock's low period is equal to the longest clock low period, and the high period is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic level 1 while another master transmits logic level 0. The losing masters immediately switch to slave receive mode and stop driving SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets a status bit to indicate the loss of arbitration.

### 54.4.1.7 Clock synchronization

Because wire AND logic is performed on SCL, a high-to-low transition on SCL affects all devices connected on the bus. The devices start counting their low period and, after a device's clock has gone low, that device holds SCL low until the clock reaches its high state. However, the change of low to high in this device clock might not change the state of SCL if another device clock is still within its low period. Therefore, the synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time; see the following diagram. When all applicable devices have counted off their low period, the synchronized clock SCL is released and pulled high. Afterward there is no difference between the device clocks and the state of SCL, and all devices start counting their high periods. The first device to complete its high period pulls SCL low again.

**Figure 54-39. I2C clock synchronization**

### 54.4.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. A slave device may hold SCL low after completing a single byte transfer (9 bits). In this case, it halts the bus clock and forces the master clock into wait states until the slave releases SCL.

### 54.4.1.9 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master drives SCL low, a slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL low period, the resulting SCL bus signal's low period is stretched. In other words, the SCL bus signal's low period is increased to be the same length as the slave's SCL low period.

### 54.4.1.10 I2C divider and hold values

#### NOTE

For some cases on some devices, the SCL divider value may vary by  $\pm 2$  or  $\pm 4$  when ICR's value ranges from 00h to 0Fh. These potentially varying SCL divider values are highlighted in the following table. For the actual SCL divider values for your device, see the chip-specific details about the I2C module.

**Table 54-41. I2C divider and hold values**

| ICR (hex) | SCL divider | SDA hold value | SCL hold (start) value | SCL hold (stop) value | ICR (hex) | SCL divider (clocks) | SDA hold (clocks) | SCL hold (start) value | SCL hold (stop) value |
|-----------|-------------|----------------|------------------------|-----------------------|-----------|----------------------|-------------------|------------------------|-----------------------|
| 00        | 20          | 7              | 6                      | 11                    | 20        | 160                  | 17                | 78                     | 81                    |

## 54.4.2 10-bit address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

### 54.4.2.1 Master-transmitter addresses a slave-receiver

The transfer direction is not changed. When a 10-bit address follows a START condition, each slave compares the first 7 bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit ( $R/\overline{W}$  direction bit) is 0. It is possible that more than one device finds a match and generates an acknowledge (A1). Each slave that finds a match compares the 8 bits of the second byte of the slave address with its own address, but only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

**Table 54-42. Master-transmitter addresses slave-receiver with a 10-bit address**

|   |  |                        |    |                                      |    |      |   |     |      |     |   |
|---|--|------------------------|----|--------------------------------------|----|------|---|-----|------|-----|---|
| S | Slave address first 7 bits<br>11110 + AD10 + AD9 | R/ $\overline{W}$<br>0 | A1 | Slave address second byte<br>AD[8:1] | A2 | Data | A | ... | Data | A/A | P |
|---|--|------------------------|----|--------------------------------------|----|------|---|-----|------|-----|---|

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

### 54.4.2.2 Master-receiver addresses a slave-transmitter

The transfer direction is changed after the second  $R/\overline{W}$  bit. Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and it tests whether the eighth ( $R/\overline{W}$ ) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

After a repeated START condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth ( $R/\overline{W}$ ) bit. However, none of them are addressed because  $R/\overline{W} = 1$  (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

**Table 54-43. Master-receiver addresses a slave-transmitter with a 10-bit address**

|   |  |                        |    |                                      |    |    |  |                        |    |      |   |     |      |   |   |
|---|--|------------------------|----|--------------------------------------|----|----|--|------------------------|----|------|---|-----|------|---|---|
| S | Slave address first 7 bits<br>11110 + AD10 + AD9 | R/ $\overline{W}$<br>0 | A1 | Slave address second byte<br>AD[8:1] | A2 | Sr | Slave address first 7 bits<br>11110 + AD10 + AD9 | R/ $\overline{W}$<br>1 | A3 | Data | A | ... | Data | A | P |
|---|--|------------------------|----|--------------------------------------|----|----|--|------------------------|----|------|---|-----|------|---|---|

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

### 54.4.3 Address matching

All received addresses can be requested in 7-bit or 10-bit address format.

- AD[7:1] in Address Register 1, which contains the I2C primary slave address, always participates in the address matching process. It provides a 7-bit address.
- If the ADEXT bit is set, AD[10:8] in Control Register 2 participates in the address matching process. It extends the I2C primary slave address to a 10-bit address.

Additional conditions that affect address matching include:

- If the GCAEN bit is set, general call participates the address matching process.
- If the ALERTEN bit is set, alert response participates the address matching process.
- If the SIICAEN bit is set, Address Register 2 participates in the address matching process.
- If the RMEN bit is set, when the Range Address register is programmed to a nonzero value, any address within the range of values of Address Register 1 (excluded) and the Range Address register (included) participates in the address matching process. The Range Address register must be programmed to a value greater than the value of Address Register 1.

When the I2C module responds to one of these addresses, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the Data register after the first byte transfer to determine that the address is matched.

## 54.4.4 System management bus specification

SMBus provides a control bus for system and power management related tasks. A system can use SMBus to pass messages to and from devices instead of tripping individual control lines.

Removing the individual control lines reduces pin count. Accepting messages ensures future expandability. With the system management bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status.

### 54.4.4.1 Timeouts

The  $T_{\text{TIMEOUT,MIN}}$  parameter allows a master or slave to conclude that a defective device is holding the clock low indefinitely or a master is intentionally trying to drive devices off the bus. The slave device must release the bus (stop driving the bus and let SCL and SDA float high) when it detects any single clock held low longer than  $T_{\text{TIMEOUT,MIN}}$ . Devices that have detected this condition must reset their communication and be able to receive a new START condition within the timeframe of  $T_{\text{TIMEOUT,MAX}}$ .

SMBus defines a clock low timeout,  $T_{\text{TIMEOUT}}$ , of 35 ms, specifies  $T_{\text{LOW:SEXT}}$  as the cumulative clock low extend time for a slave device, and specifies  $T_{\text{LOW:MEXT}}$  as the cumulative clock low extend time for a master device.

#### 54.4.4.1.1 SCL low timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than a timeout value condition. Devices that have detected the timeout condition must reset the communication. When the I2C module is an active master, if it detects that SMBCLK low has exceeded the value of  $T_{\text{TIMEOUT,MIN}}$ , it must generate a stop condition within or after the current data byte in the transfer process. When the I2C module is a slave, if it detects the  $T_{\text{TIMEOUT,MIN}}$  condition, it resets its communication and is then able to receive a new START condition.

### 54.4.4.1.2 SCL high timeout

When the I2C module has determined that the SMBCLK and SMBDAT signals have been high for at least  $T_{HIGH:MAX}$ , it assumes that the bus is idle.

A HIGH timeout occurs after a START condition appears on the bus but before a STOP condition appears on the bus. Any master detecting this scenario can assume the bus is free when either of the following occurs:

- SHTF1 rises.
- The BUSY bit is high and SHTF1 is high.

When the SMBDAT signal is low and the SMBCLK signal is high for a period of time, another kind of timeout occurs. The time period must be defined in software. SHTF2 is used as the flag when the time limit is reached. This flag is also an interrupt resource, so it triggers IICIF.

### 54.4.4.1.3 CSMBCLK TIMEOUT MEXT and CSMBCLK TIMEOUT SEXT

The following figure illustrates the definition of the timeout intervals  $T_{LOW:SEXT}$  and  $T_{LOW:MEXT}$ . When in master mode, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{LOW:MEXT}$  within a byte, where each byte is defined as START-to-ACK, ACK-to-ACK, or ACK-to-STOP. When CSMBCLK TIMEOUT MEXT occurs, SMBus MEXT rises and also triggers the SLTF.

Figure 54-40. Timeout measurement intervals

A master is allowed to abort the transaction in progress to any slave that violates the  $T_{LOW:SEXT}$  or  $T_{TIMEOUT,MIN}$  specifications. To abort the transaction, the master issues a STOP condition at the conclusion of the byte transfer in progress. When a slave, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{LOW:SEXT}$  during any message from the initial START to the STOP. When CSMBCLK TIMEOUT SEXT occurs, SEXT rises and also triggers SLTF.

**NOTE**

CSMBCLK TIMEOUT SEXT and CSMBCLK TIMEOUT MEXT are optional functions that are implemented in the second step.

**54.4.4.2 FAST ACK and NACK**

To improve reliability and communication robustness, implementation of packet error checking (PEC) by SMBus devices is optional for SMBus devices but required for devices participating in and only during the address resolution protocol (ARP) process. The PEC is a CRC-8 error checking byte, calculated on all the message bytes. The PEC is appended to the message by the device that supplied the last data byte. If the PEC is present but not correct, a NACK is issued by the receiver. Otherwise an ACK is issued. To calculate the CRC-8 by software, this module can hold the SCL line low after receiving the eighth SCL (8th bit) if this byte is a data byte. So software can determine whether an ACK or NACK should be sent to the bus by setting or clearing the TXAK bit if the FACK (fast ACK/NACK enable) bit is enabled.

SMBus requires a device always to acknowledge its own address, as a mechanism to detect the presence of a removable device (such as a battery or docking station) on the bus. In addition to indicating a slave device busy condition, SMBus uses the NACK mechanism to indicate the reception of an invalid command or invalid data. Because such a condition may occur on the last byte of the transfer, SMBus devices are required to have the ability to generate the not acknowledge after the transfer of each byte and before the completion of the transaction. This requirement is important because SMBus does not provide any other resend signaling. This difference in the use of the NACK signaling has implications on the specific implementation of the SMBus port, especially in devices that handle critical system data such as the SMBus host and the SBS components.

**NOTE**

In the last byte of master receive slave transmit mode, the master must send a NACK to the bus, so FACK must be switched off before the last byte transmits.

**54.4.5 Resets**

The I2C module is disabled after a reset. The I2C module cannot cause a core reset.

## 54.4.6 Interrupts

The I2C module generates an interrupt when any of the events in the table found here occur, provided that the IICIE bit is set.

The interrupt is driven by the IICIF bit (of the I2C Status Register) and masked with the IICIE bit (of the I2C Control Register 1). The IICIF bit must be cleared (by software) by writing 1 to it in the interrupt routine. The SMBus timeouts interrupt is driven by SLTF and masked with the IICIE bit. The SLTF bit must be cleared by software by writing 1 to it in the interrupt routine. You can determine the interrupt type by reading the Status Register.

### NOTE

In master receive mode, the FACK bit must be set to zero before the last byte transfer.

**Table 54-44. Interrupt summary**

| Interrupt source                  | Status | Flag  | Local enable    |
|-----------------------------------|--------|-------|-----------------|
| Complete 1-byte transfer          | TCF    | IICIF | IICIE           |
| Match of received calling address | IAAS   | IICIF | IICIE           |
| Arbitration lost                  | ARBL   | IICIF | IICIE           |
| SMBus SCL low timeout             | SLTF   | IICIF | IICIE           |
| SMBus SCL high SDA low timeout    | SHTF2  | IICIF | IICIE & SHTF2IE |
| Wakeup from stop or wait mode     | IAAS   | IICIF | IICIE & WUEN    |

### 54.4.6.1 Byte transfer interrupt

The Transfer Complete Flag (TCF) bit is set at the falling edge of the ninth clock to indicate the completion of a byte and acknowledgement transfer. When FACK is enabled, TCF is then set at the falling edge of eighth clock to indicate the completion of byte.

### 54.4.6.2 Address detect interrupt

When the calling address matches the programmed slave address (I2C Address Register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the Status Register is set. The CPU is interrupted, provided the IICIE bit is set. The CPU must check the SRW bit and set its Tx mode accordingly.

### 54.4.6.3 Exit from low-power/stop modes

The slave receive input detect circuit and address matching feature are still active on low power modes (wait and stop). An asynchronous input matching slave address or general call address brings the CPU out of low power/stop mode if the interrupt is not masked. Therefore, TCF and IAAS both can trigger this interrupt.

### 54.4.6.4 Arbitration lost interrupt

The I2C is a true multimaster bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The I2C module asserts the arbitration-lost interrupt when it loses the data arbitration process and the ARBL bit in the Status Register is set.

Arbitration is lost in the following circumstances:

1. SDA is sampled as low when the master drives high during an address or data transmit cycle.
2. SDA is sampled as low when the master drives high during the acknowledge bit of a data receive cycle.
3. A START cycle is attempted when the bus is busy.
4. A repeated START cycle is requested in slave mode.
5. A STOP condition is detected when the master did not request it.

The ARBL bit must be cleared (by software) by writing 1 to it.

### 54.4.6.5 Timeout interrupt in SMBus

When the IICIE bit is set, the I2C module asserts a timeout interrupt (outputs SLTF and SHTF2) upon detection of any of the mentioned timeout conditions, with one exception. The SCL high and SDA high TIMEOUT mechanism must not be used to influence the timeout interrupt output, because this timeout indicates an idle condition on the bus. SHTF1 rises when it matches the SCL high and SDA high TIMEOUT and falls automatically just to indicate the bus status. The SHTF2's timeout period is the same as that of SHTF1, which is short compared to that of SLTF, so another control bit, SHTF2IE, is added to enable or disable it.

### 54.4.7 Programmable input glitch filter

An I2C glitch filter has been added outside legacy I2C modules but within the I2C package. This filter can absorb glitches on the I2C clock and data lines for the I2C module.

The width of the glitch to absorb can be specified in terms of the number of (half) I2C module clock cycles. A single Programmable Input Glitch Filter control register is provided. Effectively, any down-up-down or up-down-up transition on the data line that occurs within the number of clock cycles programmed in this register is ignored by the I2C module. The programmer must specify the size of the glitch (in terms of I2C module clock cycles) for the filter to absorb and not pass.

**Figure 54-41. Programmable input glitch filter diagram**

### 54.4.8 Address matching wake-up

When a primary, range, or general call address match occurs when the I2C module is in slave receive mode, the MCU wakes from a low power mode where no peripheral bus is running.

After the address matching IAAS bit is set, an interrupt is sent at the end of address matching to wake the core.

**NOTE**

During the wake-up process, if an external master continues to send data to the slave, the baud rate under Stop mode must be less than 50 kbit/s. To avoid the slower baud rate under Stop mode, the master can add a short delay in firmware to wait until the wake-up process is complete and then send data.

**NOTE**

Wake-up caused by an address match is not supported for SMBus mode.

### 54.4.9 DMA support

If the DMAEN bit is cleared and the IICIE bit is set, an interrupt condition generates an interrupt request.

If the DMAEN bit is set and the IICIE bit is set, an interrupt condition generates a DMA request instead. DMA requests are generated by the transfer complete flag (TCF).

If the DMAEN bit is set, only the TCF initiates a DMA request. All other events generate CPU interrupts.

#### NOTE

Before the last byte of master receive mode, TXAK must be set to send a NACK after the last byte's transfer. Therefore, the DMA must be disabled before the last byte's transfer.

#### NOTE

In 10-bit address mode transmission, the addresses to send occupy 2–3 bytes. During this transfer period, the DMA must be disabled because the C1 register is written to send a repeat start or to change the transfer direction.

## 54.5 Initialization/application information

### Module Initialization (Slave)

1. Write: Control Register 2
  - to enable or disable general call
  - to select 10-bit or 7-bit addressing mode
2. Write: Address Register 1 to set the slave address
3. Write: Control Register 1 to enable the I2C module and interrupts
4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
5. Initialize RAM variables used to achieve the routine shown in the following figure

### Module Initialization (Master)

1. Write: Frequency Divider register to set the I2C baud rate (see example in description of [ICR](#))
2. Write: Control Register 1 to enable the I2C module and interrupts
3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data

4. Initialize RAM variables used to achieve the routine shown in the following figure
5. Write: Control Register 1 to enable TX
6. Write: Control Register 1 to enable MST (master mode)
7. Write: Data register with the address of the target slave (the LSB of this byte determines whether the communication is master receive or transmit)

The routine shown in the following figure encompasses both master and slave I2C operations. For slave operation, an incoming I2C message that contains the proper address begins I2C communication. For master operation, communication must be initiated by writing the Data register. An example of an I2C driver which implements many of the steps described here is available in [AN4342: Using the Inter-Integrated Circuit on ColdFire+ and Kinetis](#) .

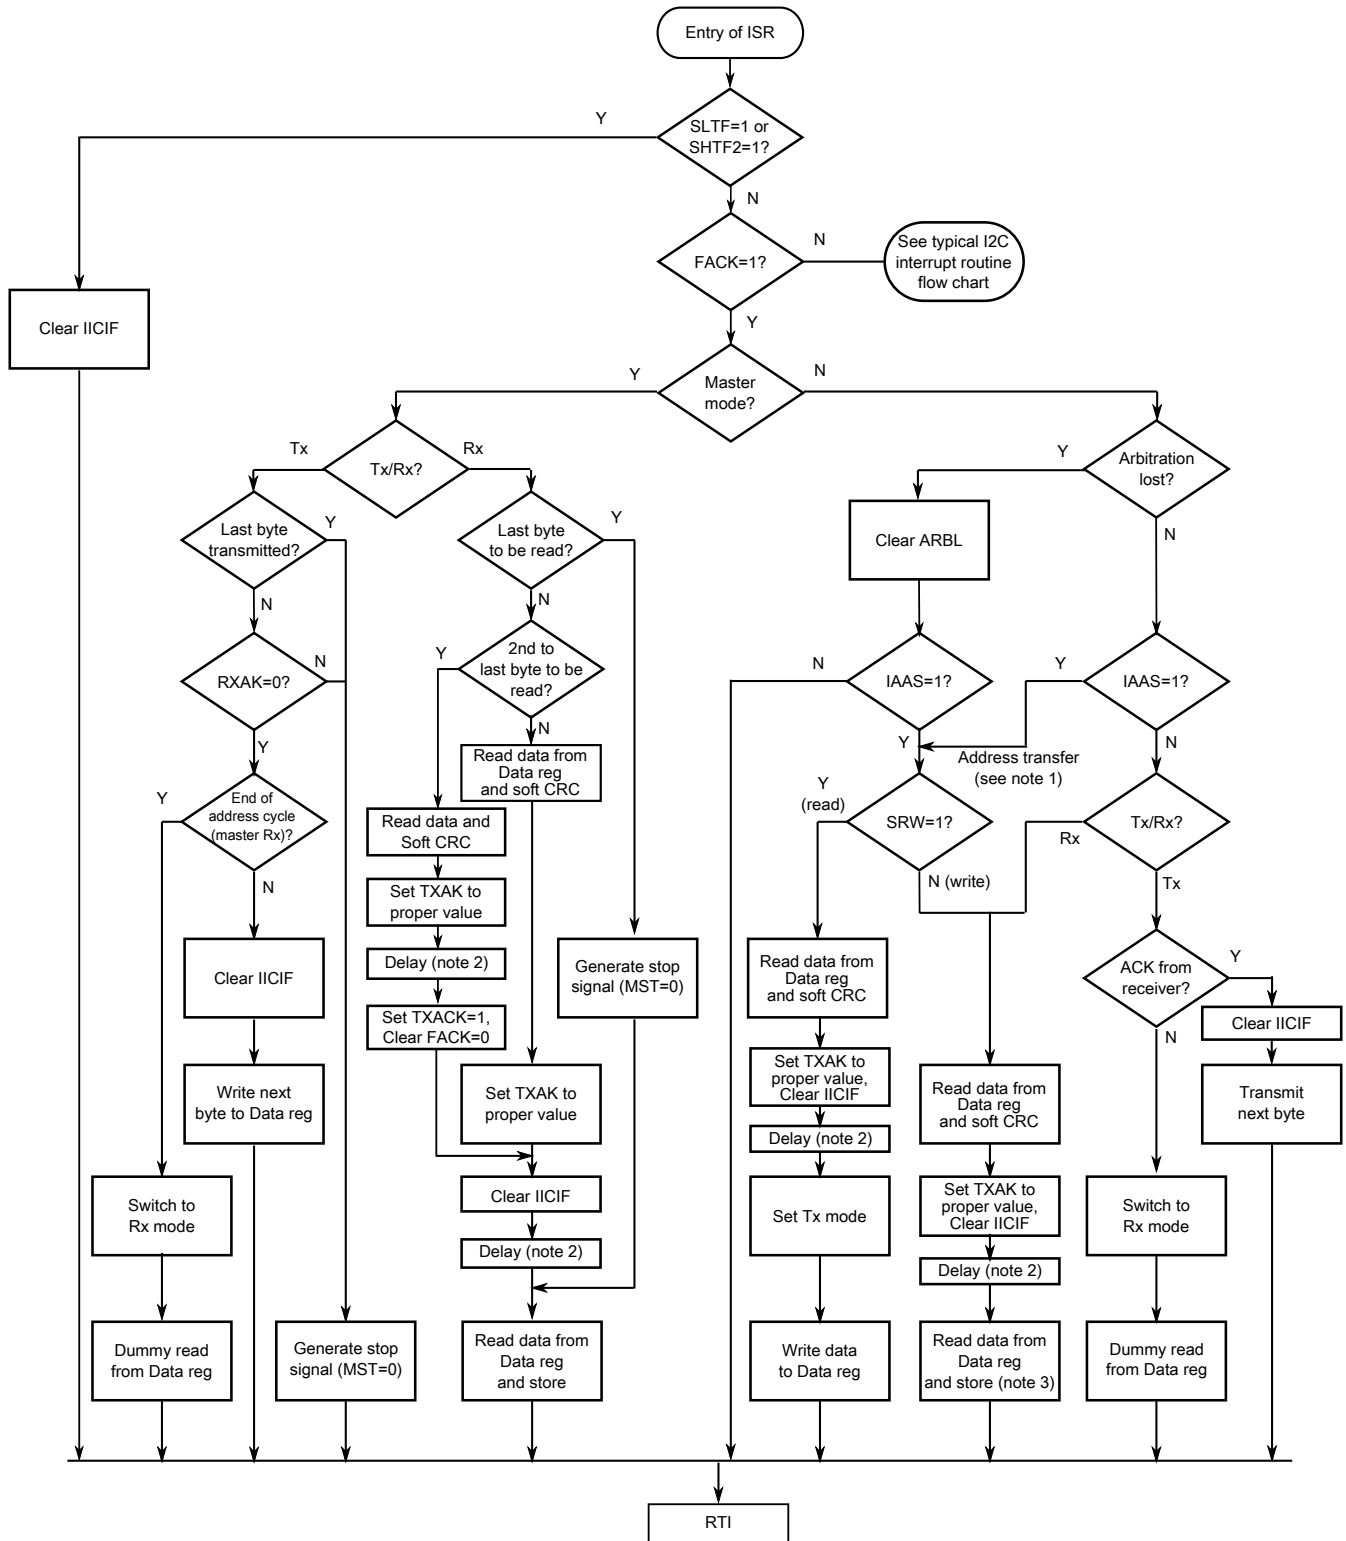

Notes:

1. If general call is enabled, check to determine if the received address is a general call address (0x00). If the received address is a general call address, the general call must be handled by user software.
2. When 10-bit addressing addresses a slave, the slave sees an interrupt following the first byte of the extended address. Ensure that for this interrupt, the contents of the Data register are ignored and not treated as a valid data transfer.

Figure 54-42. Typical I2C interrupt routine

Notes:

1. If general call or SIICAEN is enabled, check to determine if the received address is a general call address (0x00) or an SMBus device default address. In either case, they must be handled by user software.
2. In receive mode, one bit time delay may be needed before the first and second data reading, to wait for the possible longest time period (in worst case) of the 9th SCL cycle.
3. This read is a dummy read in order to reset the SMBus receiver state machine.

**Figure 54-43. Typical I2C SMBus interrupt routine**

# Chapter 55

## Universal Asynchronous Receiver/Transmitter (UART)

### 55.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The UART allows asynchronous serial communication with peripheral devices and CPUs.

#### 55.1.1 Features

The UART includes the following features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- 13-bit baud rate selection with /32 fractional divide, based on the module clock frequency
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable transmitter output polarity
- Programmable receive input polarity
- Up to 14-bit break character transmission.

- 11-bit break character detection option
- Independent FIFO structure for transmit and receive
- Two receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
- Address match feature in the receiver to reduce address mark wakeup ISR overhead
- Ability to select MSB or LSB to be first bit on wire
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Support for ISO 7816 protocol to interface with SIM cards and smart cards
  - Support for T=0 and T=1 protocols
  - Automatic retransmission of NACK'd packets with programmable retry threshold
  - Support for 11 and 12 ETU transfers
  - Detection of initial packet and automated transfer parameter programming
  - Interrupt-driven operation with seven ISO-7816 specific interrupts:
    - Wait time violated
    - Character wait time violated
    - Block wait time violated
    - Initial frame detected
    - Transmit error threshold exceeded
    - Receive error threshold exceeded
    - Guard time violated
- Support for CEA709.1-B protocol used in building automation and home networking systems
  - Automatic clock resynchronization
  - Support for collision detection
- Interrupt-driven operation with flags, not specific to ISO-7816 support

- Transmitter data buffer at or below watermark
  - Transmission complete
  - Receiver data buffer at or above watermark
  - Idle receiver input
  - Receiver data buffer overrun
  - Receiver data buffer underflow
  - Transmit data buffer overflow
  - Noise error
  - Framing error
  - Parity error
  - Active edge on receive pin
  - LIN break detect
- Receiver framing error detection
  - Hardware parity generation and checking
  - 1/16 bit-time noise detection
  - DMA interface

## 55.1.2 Modes of operation

The UART functions in the same way in all the normal modes.

It has the following low power modes:

- Wait mode
- Stop mode

### 55.1.2.1 Run mode

This is the normal mode of operation.

### 55.1.2.2 Wait mode

UART operation in the Wait mode depends on the state of the C1[UARTSWAI] field.

- If C1[UARTSWAI] is cleared, and the CPU is in Wait mode, the UART operates normally.
- If C1[UARTSWAI] is set, and the CPU is in Wait mode, the UART clock generation ceases and the UART module enters a power conservation state.

C1[UARTSWAI] does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

Setting C1[UARTSWAI] does not affect the state of the C2[RE] or C2[TE].

If C1[UARTSWAI] is set, any ongoing transmission or reception stops at the Wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of Wait mode. Bringing the CPU out of Wait mode by reset aborts any ongoing transmission or reception and resets the UART.

### 55.1.2.3 Stop mode

The UART is inactive during Stop mode for reduced power consumption. The STOP instruction does not affect the UART register states, but the UART module clock is disabled. The UART operation resumes after an external interrupt brings the CPU out of Stop mode. Bringing the CPU out of Stop mode by reset aborts any ongoing transmission or reception and resets the UART. Entering or leaving Stop mode does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

## 55.2 UART signal descriptions

The UART signals are shown in the following table.

**Table 55-1. UART signal descriptions**

| Signal    | Description      | I/O |
|-----------|------------------|-----|
| CTS       | Clear to send    | I   |
| RTS       | Request to send  | O   |
| RXD       | Receive data     | I   |
| TXD       | Transmit data    | O   |
| Collision | Collision detect | I   |

## 55.2.1 Detailed signal descriptions

The detailed signal descriptions of the UART are shown in the following table.

**Table 55-2. UART—Detailed signal descriptions**

| Signal    | I/O | Description  |
|-----------|-----|--|
| CTS       | I   | Clear to send. Indicates whether the UART can start transmitting data when flow control is enabled.  |
|           |     | <b>State meaning</b><br>Asserted—Data transmission can start.<br>Negated—Data transmission cannot start.   |
|           |     | <b>Timing</b><br>Assertion—When transmitting device's RTS asserts.<br>Negation—When transmitting device's RTS deasserts.   |
| RTS       | O   | Request to send. When driven by the receiver, indicates whether the UART is ready to receive data. When driven by the transmitter, can enable an external transceiver during transmission.   |
|           |     | <b>State meaning</b><br>Asserted—When driven by the receiver, ready to receive data. When driven by the transmitter, enable the external transmitter.<br>Negated—When driven by the receiver, not ready to receive data. When driven by the transmitter, disable the external transmitter. |
|           |     | <b>Timing</b><br>Assertion—Can occur at any time; can assert asynchronously to the other input signals.<br>Negation—Can occur at any time; can deassert asynchronously to the other input signals.   |
| RXD       | I   | Receive data. Serial data input to receiver.   |
|           |     | <b>State meaning</b><br>Whether RXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.   |
|           |     | <b>Timing</b><br>Sampled at a frequency determined by the module clock divided by the baud rate.   |
| TXD       | O   | Transmit data. Serial data output from transmitter.  |
|           |     | <b>State meaning</b><br>Whether TXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.   |
|           |     | <b>Timing</b><br>Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing.  |
| Collision | I   | Collision Detect. Indicates if a collision is detected during Data Transmission.   |
|           |     | <b>State meaning</b><br>Asserted—Indicates a collision detection. UARTxCPW determines the length of this pulse for valid collision detection.<br>Negated—No collision detected.  |
|           |     | <b>Timing</b><br>Asserts asynchronously to other input signals.  |

## 55.3 Memory map and registers

This section provides a detailed description of all memory and registers.

Accessing reserved addresses within the memory map results in a transfer error. None of the contents of the implemented addresses are modified as a result of that access.

Only byte accesses are supported.

### UART memory map

| Absolute address (hex) | Register name                               | Width (in bits) | Access | Reset value                 | Section/page                 |
|------------------------|---|-----------------|--------|-----------------------------|------------------------------|
| 4006_A000              | UART Baud Rate Registers: High (UART0_BDH)  | 8               | R/W    | 00h                         | <a href="#">55.3.1/1800</a>  |
| 4006_A001              | UART Baud Rate Registers: Low (UART0_BDL)   | 8               | R/W    | 04h                         | <a href="#">55.3.2/1801</a>  |
| 4006_A002              | UART Control Register 1 (UART0_C1)          | 8               | R/W    | 00h                         | <a href="#">55.3.3/1802</a>  |
| 4006_A003              | UART Control Register 2 (UART0_C2)          | 8               | R/W    | 00h                         | <a href="#">55.3.4/1803</a>  |
| 4006_A004              | UART Status Register 1 (UART0_S1)           | 8               | R      | C0h                         | <a href="#">55.3.5/1805</a>  |
| 4006_A005              | UART Status Register 2 (UART0_S2)           | 8               | R/W    | 00h                         | <a href="#">55.3.6/1808</a>  |
| 4006_A006              | UART Control Register 3 (UART0_C3)          | 8               | R/W    | 00h                         | <a href="#">55.3.7/1810</a>  |
| 4006_A007              | UART Data Register (UART0_D)                | 8               | R/W    | 00h                         | <a href="#">55.3.8/1811</a>  |
| 4006_A008              | UART Match Address Registers 1 (UART0_MA1)  | 8               | R/W    | 00h                         | <a href="#">55.3.9/1812</a>  |
| 4006_A009              | UART Match Address Registers 2 (UART0_MA2)  | 8               | R/W    | 00h                         | <a href="#">55.3.10/1813</a> |
| 4006_A00A              | UART Control Register 4 (UART0_C4)          | 8               | R/W    | 00h                         | <a href="#">55.3.11/1813</a> |
| 4006_A00B              | UART Control Register 5 (UART0_C5)          | 8               | R/W    | 00h                         | <a href="#">55.3.12/1814</a> |

#### 55.3.1 UART Baud Rate Registers: High (UARTx\_BDH)

This register, along with the BDL register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting (SBR[12:0]), first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written.

BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 0h offset

#### UARTx\_BDH field descriptions

| Field        | Description  |
|--------------|--|
| 7<br>LBKDIE  | LIN Break Detect Interrupt Enable<br>Enables the LIN break detect flag, LBKDIF, to generate interrupt requests,<br>0 LBKDIF interrupt requests disabled.<br>1 LBKDIF interrupt requests enabled. |
| 6<br>RXEDGIE | RxD Input Active Edge Interrupt Enable<br>Enables the receive input active edge, RXEDGIF, to generate interrupt requests.  |

*Table continues on the next page...*

### UARTx\_BDH field descriptions (continued)

| Field         | Description  |
|---------------|--|
|               | 0 Hardware interrupts from RXEDGIF disabled using polling.<br>1 RXEDGIF interrupt request enabled.   |
| 5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4–0<br>SBR    | UART Baud Rate Bits<br><br>The baud rate for the UART is determined by the 13 SBR fields. See <a href="#">Baud rate generation</a> for details.<br><br><b>NOTE:</b> <ul style="list-style-type: none"> <li>The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0.</li> <li>Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.</li> </ul> |

### 55.3.2 UART Baud Rate Registers: Low (UARTx\_BDL)

This register, along with the BDH register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting, SBR[12:0], first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written. BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 1h offset

### UARTx\_BDL field descriptions

| Field      | Description   |
|------------|---|
| 7–0<br>SBR | UART Baud Rate Bits<br><br>The baud rate for the UART is determined by the 13 SBR fields. See <a href="#">Baud rate generation</a> for details.<br><br><b>NOTE:</b> <ul style="list-style-type: none"> <li>The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset. The baud rate generator is disabled when SBR = 0.</li> <li>Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.</li> <li>When the 1/32 narrow pulse width is selected for infrared (IrDA), the baud rate fields must be even, the least significant bit is 0. See MODEM register for more details.</li> </ul> |

### 55.3.3 UART Control Register 1 (UARTx\_C1)

This read/write register controls various optional features of the UART system.

Address: Base address + 2h offset

|       |       |          |      |   |      |     |    |    |
|-------|-------|----------|------|---|------|-----|----|----|
| Bit   | 7     | 6        | 5    | 4 | 3    | 2   | 1  | 0  |
| Read  | LOOPS | UARTSWAI | RSRC | M | WAKE | ILT | PE | PT |
| Write |       |          |      |   |      |     |    |    |
| Reset | 0     | 0        | 0    | 0 | 0    | 0   | 0  | 0  |

#### UARTx\_C1 field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>LOOPS    | <p>Loop Mode Select</p> <p>When LOOPS is set, the RxD pin is disconnected from the UART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.</p> <p>0 Normal operation.<br/>1 Loop mode where transmitter output is internally connected to receiver input. The receiver input is determined by RSRC.</p>  |
| 6<br>UARTSWAI | <p>UART Stops in Wait Mode</p> <p>0 UART clock continues to run in Wait mode.<br/>1 UART clock freezes while CPU is in Wait mode.</p>  |
| 5<br>RSRC     | <p>Receiver Source Select</p> <p>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.</p> <p>0 Selects internal loop back mode. The receiver input is internally connected to transmitter output.<br/>1 Single wire UART mode where the receiver input is connected to the transmit pin input signal.</p>   |
| 4<br>M        | <p>9-bit or 8-bit Mode Select</p> <p>This field must be set when C7816[ISO_7816E] is set/enabled.</p> <p>0 Normal—start + 8 data bits (MSB/LSB first as determined by MSBF) + stop.<br/>1 Use—start + 9 data bits (MSB/LSB first as determined by MSBF) + stop.</p>  |
| 3<br>WAKE     | <p>Receiver Wakeup Method Select</p> <p>Determines which condition wakes the UART:</p> <ul style="list-style-type: none"> <li>Address mark in the most significant bit position of a received data character, or</li> <li>An idle condition on the receive pin input signal.</li> </ul> <p>0 Idle line wakeup.<br/>1 Address mark wakeup.</p>  |
| 2<br>ILT      | <p>Idle Line Type Select</p> <p>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.</p> |

Table continues on the next page...

### UARTx\_C1 field descriptions (continued)

| Field   | Description  |
|---------|--|
|         | <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>In case the UART is programmed with ILT = 1, a logic of 1'b0 is automatically shifted after a received stop bit, therefore resetting the idle count.</li> <li>In case the UART is programmed for IDLE line wakeup (RWU = 1 and WAKE = 0), ILT has no effect on when the receiver starts counting logic 1s as idle character bits. In idle line wakeup, an idle character is recognized at anytime the receiver sees 10, 11, or 12 1s depending on the M, PE, and C4[M10] fields.</li> </ul> <p>0 Idle character bit count starts after start bit.<br/>1 Idle character bit count starts after stop bit.</p> |
| 1<br>PE | <p>Parity Enable</p> <p>Enables the parity function. When parity is enabled, parity function inserts a parity bit in the bit position immediately preceding the stop bit. This field must be set when C7816[ISO_7816E] is set/enabled.</p> <p>0 Parity function disabled.<br/>1 Parity function enabled.</p>   |
| 0<br>PT | <p>Parity Type</p> <p>Determines whether the UART generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. This field must be cleared when C7816[ISO_7816E] is set/enabled.</p> <p>0 Even parity.<br/>1 Odd parity.</p>  |

### 55.3.4 UART Control Register 2 (UARTx\_C2)

This register can be read or written at any time.

Address: Base address + 3h offset

| Bit   | 7   | 6    | 5   | 4    | 3  | 2  | 1   | 0   |
|-------|-----|------|-----|------|----|----|-----|-----|
| Read  | TIE | TCIE | RIE | ILIE | TE | RE | RWU | SBK |
| Write |     |      |     |      |    |    |     |     |
| Reset | 0   | 0    | 0   | 0    | 0  | 0  | 0   | 0   |

### UARTx\_C2 field descriptions

| Field    | Description  |
|----------|--|
| 7<br>TIE | <p>Transmitter Interrupt or DMA Transfer Enable.</p> <p>Enables S1[TDRE] to generate interrupt requests or DMA transfer requests, based on the state of C5[TDMAS].</p> <p><b>NOTE:</b> If C2[TIE] and C5[TDMAS] are both set, then TCIE must be cleared, and D[D] must not be written unless servicing a DMA request.</p> <p>0 TDRE interrupt and DMA transfer requests disabled.<br/>1 TDRE interrupt or DMA transfer requests enabled.</p> |

Table continues on the next page...

### UARTx\_C2 field descriptions (continued)

| Field     | Description  |
|-----------|--|
| 6<br>TCIE | <p>Transmission Complete Interrupt Enable</p> <p>Enables the transmission complete flag, S1[TC], to generate interrupt requests .</p> <p>0 TC interrupt requests disabled.<br/>1 TC interrupt requests enabled.</p>  |
| 5<br>RIE  | <p>Receiver Full Interrupt or DMA Transfer Enable</p> <p>Enables S1[RDRF] to generate interrupt requests or DMA transfer requests, based on the state of C5[RDMAS].</p> <p>0 RDRF interrupt and DMA transfer requests disabled.<br/>1 RDRF interrupt or DMA transfer requests enabled.</p>   |
| 4<br>ILIE | <p>Idle Line Interrupt Enable</p> <p>Enables the idle line flag, S1[IDLE], to generate interrupt requests</p> <p>0 IDLE interrupt requests disabled.<br/>1 IDLE interrupt requests enabled.</p>  |
| 3<br>TE   | <p>Transmitter Enable</p> <p>Enables the UART transmitter. TE can be used to queue an idle preamble by clearing and then setting TE. When C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block has been transmitted. This condition is detected when TL7816[TLEN] = 0 and four additional characters are transmitted.</p> <p>0 Transmitter off.<br/>1 Transmitter on.</p>   |
| 2<br>RE   | <p>Receiver Enable</p> <p>Enables the UART receiver.</p> <p>0 Receiver off.<br/>1 Receiver on.</p>   |
| 1<br>RWU  | <p>Receiver Wakeup Control</p> <p>This field can be set to place the UART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when C1[WAKE] is clear or an address match when C1[WAKE] is set. This field must be cleared when C7816[ISO_7816E] is set.</p> <p><b>NOTE:</b> RWU must be set only with C1[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by S2[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the UART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to reasserted.</p> <p>0 Normal operation.<br/>1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.</p> |
| 0<br>SBK  | <p>Send Break</p> <p>Toggling SBK sends one break character from the following: See <a href="#">Transmitting break characters</a> for the number of logic 0s for the different configurations. Toggling implies clearing the SBK field before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete</p>   |

| Field | Description   |
|-------|---|
|       | break characters (10, 11, or 12 bits, or 13 or 14 bits). Ensure that C2[TE] is asserted atleast 1 clock before assertion of this bit. <ul style="list-style-type: none"> <li>• 10, 11, or 12 logic 0s if S2[BRK13] is cleared</li> <li>• 13 or 14 logic 0s if S2[BRK13] is set.</li> </ul> This field must be cleared when C7816[ISO_7816E] is set. |
| 0     | Normal transmitter operation.   |
| 1     | Queue break characters to be sent.  |

### 55.3.5 UART Status Register 1 (UARTx\_S1)

The S1 register provides inputs to the MCU for generation of UART interrupts or DMA requests. This register can also be polled by the MCU to check the status of its fields. To clear a flag, the status register should be read followed by a read or write to D register, depending on the interrupt flag type. Other instructions can be executed between the two steps as long the handling of I/O is not compromised, but the order of operations is important for flag clearing. When a flag is configured to trigger a DMA request, assertion of the associated DMA done signal from the DMA controller clears the flag.

#### NOTE

- If the condition that results in the assertion of the flag, interrupt, or DMA request is not resolved prior to clearing the flag, the flag, and interrupt/DMA request, reasserts. For example, if the DMA or interrupt service routine fails to write sufficient data to the transmit buffer to raise it above the watermark level, the flag reasserts and generates another interrupt or DMA request.
- Reading an empty data register to clear one of the flags of the S1 register causes the FIFO pointers to become misaligned. A receive FIFO flush reinitializes the pointers. A better way to prevent this situation is to always leave one byte in FIFO and this byte will be read eventually in clearing the flag bit.

Address: Base address + 4h offset

| Bit   | 7    | 6  | 5    | 4    | 3  | 2  | 1  | 0  |
|-------|------|----|------|------|----|----|----|----|
| Read  | TDRE | TC | RDRF | IDLE | OR | NF | FE | PF |
| Write |      |    |      |      |    |    |    |    |
| Reset | 1    | 1  | 0    | 0    | 0  | 0  | 0  | 0  |

### UARTx\_S1 field descriptions

| Field     | Description  |
|-----------|--|
| 7<br>TDRE | <p>Transmit Data Register Empty Flag</p> <p>TDRE will set when the number of datawords in the transmit buffer (D and C3[T8]) is equal to or less than the number indicated by TWFIFO[TXWATER]. A character that is in the process of being transmitted is not included in the count. To clear TDRE, read S1 when TDRE is set and then write to the UART data register (D). For more efficient interrupt servicing, all data except the final value to be written to the buffer must be written to D/C3[T8]. Then S1 can be read before writing the final data value, resulting in the clearing of the TRDE flag. This is more efficient because the TDRE reasserts until the watermark has been exceeded. So, attempting to clear the TDRE with every write will be ineffective until sufficient data has been written.</p> <p>0 The amount of data in the transmit buffer is greater than the value indicated by TWFIFO[TXWATER].<br/>           1 The amount of data in the transmit buffer is less than or equal to the value indicated by TWFIFO[TXWATER] at some point in time since the flag has been cleared.</p> |
| 6<br>TC   | <p>Transmit Complete Flag</p> <p>TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by reading S1 with TC set and then doing one of the following: When C7816[ISO_7816E] is set/enabled, this field is set after any NACK signal has been received, but prior to any corresponding guard times expiring. When C6[EN709] is set/enabled, this flag is not set on transmit packet completion.</p> <ul style="list-style-type: none"> <li>• Writing to D to transmit new data.</li> <li>• Queuing a preamble by clearing and then setting C2[TE].</li> <li>• Queuing a break character by writing 1 to SBK in C2.</li> </ul> <p>0 Transmitter active (sending data, a preamble, or a break).<br/>           1 Transmitter idle (transmission activity complete).</p>   |
| 5<br>RDRF | <p>Receive Data Register Full Flag</p> <p>RDRF is set when the number of datawords in the receive buffer is equal to or more than the number indicated by RWFIFO[RXWATER]. A dataword that is in the process of being received is not included in the count. To clear RDRF, read S1 when RDRF is set and then read D. For more efficient interrupt and DMA operation, read all data except the final value from the buffer, using D/C3[T8]/ED. Then read S1 and the final data value, resulting in the clearing of the RDRF flag. Even if RDRF is set, data will continue to be received until an overrun condition occurs. RDRF is prevented from setting while S2[LBKDE] is set. Additionally, when S2[LBKDE] is set, the received datawords are stored in the receive buffer but over-write each other.</p> <p>0 The number of datawords in the receive buffer is less than the number indicated by RXWATER.<br/>           1 The number of datawords in the receive buffer is equal to or greater than the number indicated by RXWATER at some point in time since this flag was last cleared.</p>                   |
| 4<br>IDLE | <p>Idle Line Flag</p> <p>After the IDLE flag is cleared, a frame must be received (although not necessarily stored in the data buffer, for example if C2[RWU] is set), or a LIN break character must set the S2[LBKDIF] flag before an idle condition can set the IDLE flag. To clear IDLE, read UART status S1 with IDLE set and then read D. IDLE is set when either of the following appear on the receiver input:</p> <ul style="list-style-type: none"> <li>• 10 consecutive logic 1s if C1[M] = 0</li> <li>• 11 consecutive logic 1s if C1[M] = 1 and C4[M10] = 0</li> <li>• 12 consecutive logic 1s if C1[M] = 1, C4[M10] = 1, and C1[PE] = 1</li> </ul> <p>Idle detection is not supported when 7816E or EN709 is set/enabled and hence this flag is ignored.</p> <p><b>NOTE:</b> When RWU is set and WAKE is cleared, an idle line condition sets the IDLE flag if RWUID is set, else the IDLE flag does not become set.</p>  |

Table continues on the next page...

**UARTx\_S1 field descriptions (continued)**

| Field   | Description  |
|---------|--|
|         | 0 Receiver input is either active now or has never become active since the IDLE flag was last cleared.<br>1 Receiver input has become idle or the flag has not been cleared since it last asserted.  |
| 3<br>OR | Receiver Overrun Flag<br><br>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the UART data registers is not affected. If the OR flag is set, no data is stored in the data buffer even if sufficient room exists. Additionally, while the OR flag is set, the RDRF and IDLE flags are blocked from asserting, that is, transition from an inactive to an active state. To clear OR, read S1 when OR is set and then read D. See functional description for more details regarding the operation of the OR bit. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if S2[LBKDIF] is not cleared before the next data character is received. In 7816 mode, it is possible to configure a NACK to be returned by programming C7816[ONACK].<br><br>0 No overrun has occurred since the last time the flag was cleared.<br>1 Overrun has occurred or the overrun flag has not been cleared since the last overrun occurred. |
| 2<br>NF | Noise Flag<br><br>NF is set when the UART detects noise on the receiver input. NF does not become set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). When NF is set, it indicates only that a dataword has been received with noise since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has noise or that there is only one dataword in the buffer that was received with noise unless the receive buffer has a depth of one. To clear NF, read S1 and then read D. When EN709 is set/enabled, noise flag is not set.<br><br>0 No noise detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1 then there may be data in the receiver buffer that was received with noise.<br>1 At least one dataword was received with noise detected since the last time the flag was cleared.   |
| 1<br>FE | Framing Error Flag<br><br>FE is set when a logic 0 is accepted as the stop bit. FE does not set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). FE inhibits further data reception until it is cleared. To clear FE, read S1 with FE set and then read D. The last data in the receive buffer represents the data that was received with the frame error enabled. Framing errors are not supported when 7816E is set/enabled. However, if this flag is set, data is still not received in 7816 mode. Framing errors are not supported in 709 mode.<br><br>0 No framing error detected.<br>1 Framing error.   |
| 0<br>PF | Parity Error Flag<br><br>PF is set when PE is set and the parity of the received data does not match its parity bit. The PF is not set in the case of an overrun condition. When PF is set, it indicates only that a dataword was received with parity error since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has a parity error or that there is only one dataword in the buffer that was received with a parity error, unless the receive buffer has a depth of one. To clear PF, read S1 and then read D., S2[LBKDE] is disabled. Within the receive buffer structure the received dataword is tagged if it is received with a parity error. This information is available by reading the ED register prior to reading the D register.<br><br>0 No parity error detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1, then there may be data in the receive buffer what was received with a parity error.<br>1 At least one dataword was received with a parity error since the last time this flag was cleared.  |

### 55.3.6 UART Status Register 2 (UARTx\_S2)

The S2 register provides inputs to the MCU for generation of UART interrupts or DMA requests. Also, this register can be polled by the MCU to check the status of these bits. This register can be read or written at any time, with the exception of the MSBF and RXINV bits, which should be changed by the user only between transmit and receive packets.

Address: Base address + 5h offset

|       |        |         |      |       |       |       |       |     |
|-------|--------|---------|------|-------|-------|-------|-------|-----|
| Bit   | 7      | 6       | 5    | 4     | 3     | 2     | 1     | 0   |
| Read  | LBKDIF | RXEDGIF | MSBF | RXINV | RWUID | BRK13 | LBKDE | RAF |
| Write | w1c    | w1c     |      |       |       |       |       |     |
| Reset | 0      | 0       | 0    | 0     | 0     | 0     | 0     | 0   |

**UARTx\_S2 field descriptions**

| Field        | Description   |
|--------------|---|
| 7<br>LBKDIF  | <p>LIN Break Detect Interrupt Flag</p> <p>LBKDIF is set when LBKDE is set and a LIN break character is detected on the receiver input. The LIN break characters are 11 consecutive logic 0s if C1[M] = 0 or 12 consecutive logic 0s if C1[M] = 1. LBKDIF is set after receiving the last LIN break character. LBKDIF is cleared by writing a 1 to it.</p> <p>0 No LIN break character detected.<br/>1 LIN break character detected.</p>   |
| 6<br>RXEDGIF | <p>RxD Pin Active Edge Interrupt Flag</p> <p>RXEDGIF is set when an active edge occurs on the RxD pin. The active edge is falling if RXINV = 0, and rising if RXINV=1. RXEDGIF is cleared by writing a 1 to it. See for additional details. <a href="#">RXEDGIF description</a></p> <p><b>NOTE:</b> The active edge is detected only in two wire mode and on receiving data coming from the RxD pin.</p> <p>0 No active edge on the receive pin has occurred.<br/>1 An active edge on the receive pin has occurred.</p>   |
| 5<br>MSBF    | <p>Most Significant Bit First</p> <p>Setting this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode. In EN709 mode, this field affects the order of bits the same way as it does in normal mode.</p> <p>0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br/>1 MSB (bit8, bit7 or bit6) is the first bit that is transmitted following the start bit, depending on the setting of C1[M] and C1[PE]. Further, the first bit received after the start bit is identified as bit8, bit7, or bit6, depending on the setting of C1[M] and C1[PE].</p> |
| 4<br>RXINV   | <p>Receive Data Inversion</p>   |

Table continues on the next page...

### UARTx\_S2 field descriptions (continued)

| Field      | Description   |
|------------|---|
|            | <p>Setting this field reverses the polarity of the received data input. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity. A zero is represented by a short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode. In EN709 mode, this bit affects the polarity of bits the same as it does in normal mode.</p> <p><b>NOTE:</b> Setting RXINV inverts the RxD input for data bits, start and stop bits, break, and idle. When C7816[ISO7816E] is set/enabled, only the data bits and the parity bit are inverted.</p> <p>0 Receive data is not inverted.<br/>1 Receive data is inverted.</p> |
| 3<br>RWUID | <p>Receive Wakeup Idle Detect</p> <p>When RWU is set and WAKE is cleared, this field controls whether the idle character that wakes the receiver sets S1[IDLE]. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>0 S1[IDLE] is not set upon detection of an idle character.<br/>1 S1[IDLE] is set upon detection of an idle character.</p>  |
| 2<br>BRK13 | <p>Break Transmit Character Length</p> <p>Determines whether the transmit break character is 10, 11, or 12 bits long, or 13 or 14 bits long. See for the length of the break character for the different configurations. The detection of a framing error is not affected by this field. <a href="#">Transmitting break characters</a></p> <p>0 Break character is 10, 11, or 12 bits long.<br/>1 Break character is 13 or 14 bits long.</p>  |
| 1<br>LBKDE | <p>LIN Break Detection Enable</p> <p>Enables the LIN Break detection feature. While LBKDE is set, S1[RDRF], S1[NF], S1[FE], and S1[PF] are prevented from setting. When LBKDE is set, see <a href="#">. Overrun operation</a> LBKDE must be cleared when C7816[ISO7816E] is set.</p> <p>0 Break character detection is disabled.<br/>1 Break character is detected at length of 11 bit times if C1[M] = 0 or 12 bits time if C1[M] = 1.</p>   |
| 0<br>RAF   | <p>Receiver Active Flag</p> <p>RAF is set when the UART receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character when C7816[ISO7816E] is cleared/disabled. When C7816[ISO7816E] is enabled, the RAF is cleared if the C7816[TTYTYPE] = 0 expires or the C7816[TTYTYPE] = 1 expires.</p> <p><b>NOTE:</b> In case C7816[ISO7816E] is set and C7816[TTYTYPE] = 0, it is possible to configure the guard time to 12. However, if a NACK is required to be transmitted, the data transfer actually takes 13 ETU with the 13th ETU slot being an inactive buffer. Therefore, in this situation, the RAF may deassert one ETU prior to actually being inactive.</p> <p>0 UART receiver idle/inactive waiting for a start bit.<br/>1 UART receiver active, RxD input not idle.</p>   |

### 55.3.7 UART Control Register 3 (UARTx\_C3)

Writing R8 does not have any effect. TXDIR and TXINV can be changed only between transmit and receive packets.

Address: Base address + 6h offset

|       |    |    |       |       |      |      |      |      |
|-------|----|----|-------|-------|------|------|------|------|
| Bit   | 7  | 6  | 5     | 4     | 3    | 2    | 1    | 0    |
| Read  | R8 | T8 | TXDIR | TXINV | ORIE | NEIE | FEIE | PEIE |
| Write |    |    |       |       |      |      |      |      |
| Reset | 0  | 0  | 0     | 0     | 0    | 0    | 0    | 0    |

#### UARTx\_C3 field descriptions

| Field      | Description   |
|------------|---|
| 7<br>R8    | <p>Received Bit 8</p> <p>R8 is the ninth data bit received when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. The R8 value corresponds to the current data value in the UARTx_D register. To read the 9th bit, read the value of UARTx_C3[R8], then read the UARTx_D register.</p>  |
| 6<br>T8    | <p>Transmit Bit 8</p> <p>T8 is the ninth data bit transmitted when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1.</p> <p><b>NOTE:</b> If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.</p> <p>To correctly transmit the 9th bit, write UARTx_C3[T8] to the desired value, then write the UARTx_D register with the remaining data.</p>   |
| 5<br>TXDIR | <p>Transmitter Pin Data Direction in Single-Wire mode</p> <p>Determines whether the TXD pin is used as an input or output in the single-wire mode of operation. This field is relevant only to the single wire mode. When C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block is transmitted. This condition is detected when TL7816[TLEN] = 0 and 4 additional characters are transmitted. Additionally, if C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 0 and a NACK is being transmitted, the hardware automatically overrides this field as needed. In this situation, TXDIR does not reflect the temporary state associated with the NACK.</p> <p>0 TXD pin is an input in single wire mode.<br/>1 TXD pin is an output in single wire mode.</p>   |
| 4<br>TXINV | <p>Transmit Data Inversion.</p> <p>Setting this field reverses the polarity of the transmitted data output. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p><b>NOTE:</b> Setting TXINV inverts all transmitted values, including idle, break, start, and stop bits. In loop mode, if TXINV is set, the receiver gets the transmit inversion bit when RXINV is disabled. When C7816[ISO7816E] is set/enabled then only the transmitted data bits and parity bit are inverted.</p> |

Table continues on the next page...

**UARTx\_C3 field descriptions (continued)**

| Field     | Description  |
|-----------|--|
|           | 0 Transmit data is not inverted.<br>1 Transmit data is inverted.   |
| 3<br>ORIE | Overrun Error Interrupt Enable<br>Enables the overrun error flag, S1[OR], to generate interrupt requests.<br>0 OR interrupts are disabled.<br>1 OR interrupt requests are enabled.         |
| 2<br>NEIE | Noise Error Interrupt Enable<br>Enables the noise flag, S1[NF], to generate interrupt requests.<br>0 NF interrupt requests are disabled.<br>1 NF interrupt requests are enabled.           |
| 1<br>FEIE | Framing Error Interrupt Enable<br>Enables the framing error flag, S1[FE], to generate interrupt requests.<br>0 FE interrupt requests are disabled.<br>1 FE interrupt requests are enabled. |
| 0<br>PEIE | Parity Error Interrupt Enable<br>Enables the parity error flag, S1[PF], to generate interrupt requests.<br>0 PF interrupt requests are disabled.<br>1 PF interrupt requests are enabled.   |

**55.3.8 UART Data Register (UARTx\_D)**

This register is actually two separate registers. Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

**NOTE**

- In 8-bit or 9-bit data format, only UART data register (D) needs to be accessed to clear the S1[RDRF] bit (assuming receiver buffer level is less than RWFIFO[RXWATER]). The C3 register needs to be read, prior to the D register, only if the ninth bit of data needs to be captured. Similarly, the ED register needs to be read, prior to the D register, only if the additional flag data for the dataword needs to be captured.
- In the normal 8-bit mode (M bit cleared) if the parity is enabled, you get seven data bits and one parity bit. That one parity bit is loaded into the D register. So, for the data

bits, mask off the parity bit from the value you read out of this register.

- When transmitting in 9-bit data format and using 8-bit write instructions, write first to transmit bit 8 in UART control register 3 (C3[T8]), then D. A write to C3[T8] stores the data in a temporary register. If D register is written first, and then the new data on data bus is stored in D, the temporary value written by the last write to C3[T8] gets stored in the C3[T8] register.

Address: Base address + 7h offset

**UARTx\_D field descriptions**

| Field     | Description  |
|-----------|--|
| 7-0<br>RT | Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register. |

### 55.3.9 UART Match Address Registers 1 (UARTx\_MA1)

The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. These registers can be read and written at anytime.

Address: Base address + 8h offset

**UARTx\_MA1 field descriptions**

| Field     | Description   |
|-----------|---------------|
| 7-0<br>MA | Match Address |

### 55.3.10 UART Match Address Registers 2 (UARTx\_MA2)

These registers can be read and written at anytime. The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded.

Address: Base address + 9h offset

**UARTx\_MA2 field descriptions**

| Field     | Description   |
|-----------|---------------|
| 7-0<br>MA | Match Address |

### 55.3.11 UART Control Register 4 (UARTx\_C4)

Address: Base address + Ah offset

**UARTx\_C4 field descriptions**

| Field      | Description   |
|------------|---|
| 7<br>MAEN1 | <p>Match Address Mode Enable 1</p> <p>See <a href="#">Match address operation</a> for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN2 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA1 register. If no match occurs, the data is discarded. If match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p>   |
| 6<br>MAEN2 | <p>Match Address Mode Enable 2</p> <p>See <a href="#">Match address operation</a> for more information.</p> <p>0 All data received is transferred to the data buffer if MAEN1 is cleared.</p> <p>1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA2 register. If no match occurs, the data is discarded. If a match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> |

*Table continues on the next page...*

### UARTx\_C4 field descriptions (continued)

| Field       | Description   |
|-------------|---|
| 5<br>M10    | <p>10-bit Mode select</p> <p>Causes a tenth, non-memory mapped bit to be part of the serial transmission. This tenth bit is generated and interpreted as a parity bit. The M10 field does not affect the LIN send or detect break behavior. If M10 is set, then both C1[M] and C1[PE] must also be set. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>See <a href="#">Data format (non ISO-7816)</a> for more information.</p> <p>0 The parity bit is the ninth bit in the serial transmission.<br/>           1 The parity bit is the tenth bit in the serial transmission.</p> |
| 4–0<br>BRFA | <p>Baud Rate Fine Adjust</p> <p>This bit field is used to add more timing resolution to the average baud frequency, in increments of 1/32. See <a href="#">Baud rate generation</a> for more information.</p>   |

### 55.3.12 UART Control Register 5 (UARTx\_C5)

Address: Base address + Bh offset

### UARTx\_C5 field descriptions

| Field         | Description  |
|---------------|--|
| 7<br>TDMAS    | <p>Transmitter DMA Select</p> <p>Configures the transmit data register empty flag, S1[TDRE], to generate interrupt or DMA requests if C2[TIE] is set.</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>If C2[TIE] is cleared, TDRE DMA and TDRE interrupt request signals are not asserted when the TDRE flag is set, regardless of the state of TDMAS.</li> <li>If C2[TIE] and TDMAS are both set, then C2[TCIE] must be cleared, and D must not be written unless a DMA request is being serviced.</li> </ul> <p>0 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE interrupt request signal is asserted to request interrupt service.<br/>           1 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE DMA request signal is asserted to request a DMA transfer.</p> |
| 6<br>Reserved | <p>This field is reserved.<br/>           This read-only field is reserved and always has the value 0.</p>   |
| 5<br>RDMAS    | <p>Receiver Full DMA Select</p> <p>Configures the receiver data register full flag, S1[RDRF], to generate interrupt or DMA requests if C2[RIE] is set.</p> <p><b>NOTE:</b> If C2[RIE] is cleared, and S1[RDRF] is set, the RDRF DMA and RDRF interrupt request signals are not asserted, regardless of the state of RDMAS.</p>   |

Table continues on the next page...

**UARTx\_C5 field descriptions (continued)**

| Field           | Description   |
|-----------------|---|
| 0               | If C2[RIE] and S1[RDRF] are set, the RDRF interrupt request signal is asserted to request an interrupt service. |
| 1               | If C2[RIE] and S1[RDRF] are set, the RDRF DMA request signal is asserted to request a DMA transfer.             |
| 4<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                         |
| 3–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                         |

**55.3.13 UART Extended Data Register (UARTx\_ED)**

This register contains additional information flags that are stored with a received dataword. This register may be read at any time but contains valid data only if there is a dataword in the receive FIFO.

**NOTE**

- The data contained in this register represents additional information regarding the conditions on which a dataword was received. The importance of this data varies with the application, and in some cases maybe completely optional. These fields automatically update to reflect the conditions of the next dataword whenever D is read.
- If S1[NF] and S1[PF] have not been set since the last time the receive buffer was empty, the NOISY and PARITYE fields will be zero.

Address: Base address + Ch offset

|       |       |         |   |   |   |   |   |   |
|-------|-------|---------|---|---|---|---|---|---|
| Bit   | 7     | 6       | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | NOISY | PARITYE | 0 |   |   |   |   |   |
| Write |       |         |   |   |   |   |   |   |
| Reset | 0     | 0       | 0 | 0 | 0 | 0 | 0 | 0 |

**UARTx\_ED field descriptions**

| Field        | Description  |
|--------------|--|
| 7<br>NOISY   | The current received dataword contained in D and C3[R8] was received with noise.<br>0 The dataword was received without noise.<br>1 The data was received with noise.                                |
| 6<br>PARITYE | The current received dataword contained in D and C3[R8] was received with a parity error.<br>0 The dataword was received without a parity error.<br>1 The dataword was received with a parity error. |

*Table continues on the next page...*

### UARTx\_ED field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 5–0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

### 55.3.14 UART Modem Register (UARTx\_MODEM)

The MODEM register controls options for setting the modem configuration.

#### NOTE

RXRTSE, TXRTSPOL, TXRTSE, and TXCTSE must all be cleared when C7816[ISO7816EN] is enabled. This will cause the RTS to deassert during ISO-7816 wait times. The ISO-7816 protocol does not use the RTS and CTS signals.

Address: Base address + Dh offset

| Bit   | 7 | 6 | 5 | 4 | 3      | 2        | 1      | 0      |
|-------|---|---|---|---|--------|----------|--------|--------|
| Read  | 0 |   |   |   | RXRTSE | TXRTSPOL | TXRTSE | TXCTSE |
| Write | 0 |   |   |   | 0      | 0        | 0      | 0      |
| Reset | 0 | 0 | 0 | 0 | 0      | 0        | 0      | 0      |

### UARTx\_MODEM field descriptions

| Field           | Description  |
|-----------------|--|
| 7–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 3<br>RXRTSE     | Receiver request-to-send enable<br><br>Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun.<br><br><b>NOTE:</b> Do not set both RXRTSE and TXRTSE.<br><br>0 The receiver has no effect on RTS.<br>1 RTS is deasserted if the number of characters in the receiver data register (FIFO) is equal to or greater than RWFIFO[RXWATER]. RTS is asserted when the number of characters in the receiver data register (FIFO) is less than RWFIFO[RXWATER]. See <a href="#">Hardware flow control</a> |
| 2<br>TXRTSPOL   | Transmitter request-to-send polarity<br><br>Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set.<br><br>0 Transmitter RTS is active low.<br>1 Transmitter RTS is active high.  |
| 1<br>TXRTSE     | Transmitter request-to-send enable<br><br>Controls RTS before and after a transmission.  |

Table continues on the next page...

### UARTx\_MODEM field descriptions (continued)

| Field       | Description   |
|-------------|---|
|             | 0 The transmitter has no effect on RTS.<br>1 When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. (FIFO)(FIFO)  |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br><br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br><br>0 CTS has no effect on the transmitter.<br>1 Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

### 55.3.15 UART Infrared Register (UARTx\_IR)

The IR register controls options for setting the infrared configuration.

Address: Base address + Eh offset

### UARTx\_IR field descriptions

| Field           | Description  |
|-----------------|--|
| 7-3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 2<br>IREN       | Infrared enable<br><br>Enables/disables the infrared modulation/demodulation.<br><br>0 IR disabled.<br>1 IR enabled.   |
| 1-0<br>TNP      | Transmitter narrow pulse<br><br>Enables whether the UART transmits a 1/16, 3/16, 1/32, or 1/4 narrow pulse.<br><br>00 3/16.<br>01 1/16.<br>10 1/32.<br>11 1/4. |

### 55.3.16 UART FIFO Parameters (UARTx\_PFIFO)

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when C2[RE] and C2[TE] are cleared/not set and when the data buffer/FIFO is empty.

Address: Base address + 10h offset

\* Notes:

- TXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.
- RXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.

#### UARTx\_PFIFO field descriptions

| Field             | Description  |
|-------------------|--|
| 7<br>TXFE         | <p>Transmit FIFO Enable</p> <p>When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field.</p> <p>0 Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support).<br/>1 Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.</p> |
| 6-4<br>TXFIFOSIZE | <p>Transmit FIFO. Buffer Depth</p> <p>The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only.</p> <p>000 Transmit FIFO/Buffer depth = 1 dataword.<br/>001 Transmit FIFO/Buffer depth = 4 datawords.<br/>010 Transmit FIFO/Buffer depth = 8 datawords.<br/>011 Transmit FIFO/Buffer depth = 16 datawords.<br/>100 Transmit FIFO/Buffer depth = 32 datawords.<br/>101 Transmit FIFO/Buffer depth = 64 datawords.<br/>110 Transmit FIFO/Buffer depth = 128 datawords.<br/>111 Reserved.</p>  |
| 3<br>RXFE         | <p>Receive FIFO Enable</p>   |

Table continues on the next page...

### UARTx\_PFIFO field descriptions (continued)

| Field             | Description   |
|-------------------|---|
|                   | <p>When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field.</p> <p>0 Receive FIFO is not enabled. Buffer is depth 1. (Legacy support)<br/>           1 Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE.</p>         |
| 2–0<br>RXFIFOSIZE | <p>Receive FIFO. Buffer Depth</p> <p>The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only.</p> <p>000 Receive FIFO/Buffer depth = 1 dataword.<br/>           001 Receive FIFO/Buffer depth = 4 datawords.<br/>           010 Receive FIFO/Buffer depth = 8 datawords.<br/>           011 Receive FIFO/Buffer depth = 16 datawords.<br/>           100 Receive FIFO/Buffer depth = 32 datawords.<br/>           101 Receive FIFO/Buffer depth = 64 datawords.<br/>           110 Receive FIFO/Buffer depth = 128 datawords.<br/>           111 Reserved.</p> |

### 55.3.17 UART FIFO Control Register (UARTx\_CFIFO)

This register provides the ability to program various control fields for FIFO operation. This register may be read or written at any time. Note that writing to TXFLUSH and RXFLUSH may result in data loss and requires careful action to prevent unintended/unpredictable behavior. Therefore, it is recommended that TE and RE be cleared prior to flushing the corresponding FIFO.

Address: Base address + 11h offset

|       |         |         |   |   |   |       |       |       |
|-------|---------|---------|---|---|---|-------|-------|-------|
| Bit   | 7       | 6       | 5 | 4 | 3 | 2     | 1     | 0     |
| Read  | 0       | 0       | 0 |   |   | RXOFE | TXOFE | RXUFE |
| Write | TXFLUSH | RXFLUSH |   |   |   |       |       |       |
| Reset | 0       | 0       | 0 | 0 | 0 | 0     | 0     | 0     |

#### UARTx\_CFIFO field descriptions

| Field        | Description  |
|--------------|--|
| 7<br>TXFLUSH | <p>Transmit FIFO/Buffer Flush</p> <p>Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register.</p> <p>0 No flush operation occurs.<br/>           1 All data in the transmit FIFO/Buffer is cleared out.</p> |

Table continues on the next page...

### UARTx\_CFIFO field descriptions (continued)

| Field           | Description   |
|-----------------|---|
| 6<br>RXFLUSH    | Receive FIFO/Buffer Flush<br><br>Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register.<br><br>0 No flush operation occurs.<br>1 All data in the receive FIFO/buffer is cleared out. |
| 5–3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>RXOFE      | Receive FIFO Overflow Interrupt Enable<br><br>When this field is set, the RXOF flag generates an interrupt to the host.<br><br>0 RXOF flag does not generate an interrupt to the host.<br>1 RXOF flag generates an interrupt to the host.   |
| 1<br>TXOFE      | Transmit FIFO Overflow Interrupt Enable<br><br>When this field is set, the TXOF flag generates an interrupt to the host.<br><br>0 TXOF flag does not generate an interrupt to the host.<br>1 TXOF flag generates an interrupt to the host.  |
| 0<br>RXUFE      | Receive FIFO Underflow Interrupt Enable<br><br>When this field is set, the RXUF flag generates an interrupt to the host.<br><br>0 RXUF flag does not generate an interrupt to the host.<br>1 RXUF flag generates an interrupt to the host.  |

### 55.3.18 UART FIFO Status Register (UARTx\_SFIFO)

This register provides status information regarding the transmit and receiver buffers/FIFOs, including interrupt information. This register may be written to or read at any time.

Address: Base address + 12h offset

| Bit   | 7      | 6      | 5 | 4 | 3 | 2    | 1    | 0    |
|-------|--------|--------|---|---|---|------|------|------|
| Read  | TXEMPT | RXEMPT | 0 |   |   | RXOF | TXOF | RXUF |
| Write |        |        |   |   |   | w1c  | w1c  | w1c  |
| Reset | 1      | 1      | 0 | 0 | 0 | 0    | 0    | 0    |

### UARTx\_SFIFO field descriptions

| Field       | Description   |
|-------------|---|
| 7<br>TXEMPT | Transmit Buffer/FIFO Empty<br><br>Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register. |

*Table continues on the next page...*

**UARTx\_SFIFO field descriptions (continued)**

| Field           | Description   |
|-----------------|---|
|                 | 0 Transmit buffer is not empty.<br>1 Transmit buffer is empty.  |
| 6<br>RXEMPT     | Receive Buffer/FIFO Empty<br><br>Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register.<br><br>0 Receive buffer is not empty.<br>1 Receive buffer is empty.  |
| 5-3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>RXOF       | Receiver Buffer Overflow Flag<br><br>Indicates that more data has been written to the receive buffer than it can hold. This field will assert regardless of the value of CFIFO[RXOFE]. However, an interrupt will be issued to the host only if CFIFO[RXOFE] is set. This flag is cleared by writing a 1.<br><br>0 No receive buffer overflow has occurred since the last time the flag was cleared.<br>1 At least one receive buffer overflow has occurred since the last time the flag was cleared.       |
| 1<br>TXOF       | Transmitter Buffer Overflow Flag<br><br>Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of CFIFO[TXOFE]. However, an interrupt will be issued to the host only if CFIFO[TXOFE] is set. This flag is cleared by writing a 1.<br><br>0 No transmit buffer overflow has occurred since the last time the flag was cleared.<br>1 At least one transmit buffer overflow has occurred since the last time the flag was cleared. |
| 0<br>RXUF       | Receiver Buffer Underflow Flag<br><br>Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of CFIFO[RXUFE]. However, an interrupt will be issued to the host only if CFIFO[RXUFE] is set. This flag is cleared by writing a 1.<br><br>0 No receive buffer underflow has occurred since the last time the flag was cleared.<br>1 At least one receive buffer underflow has occurred since the last time the flag was cleared.     |

**55.3.19 UART FIFO Transmit Watermark (UARTx\_TWFIFO)**

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when C2[TE] is not set. Changing the value of the watermark will not clear the S1[TDRE] flag.

Address: Base address + 13h offset

### UARTx\_TWFIFO field descriptions

| Field          | Description  |
|----------------|--|
| 7-0<br>TXWATER | <p>Transmit Watermark</p> <p>When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt via S1[TDRE] or a DMA request via C5[TDMAS] is generated as determined by C5[TDMAS] and C2[TIE]. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by PFIFO[TXFIFOSIZE] and PFIFO[TXFE].</p> |

### 55.3.20 UART FIFO Transmit Count (UARTx\_TCFIFO)

This is a read only register that indicates how many datawords are currently in the transmit buffer/FIFO. It may be read at any time.

Address: Base address + 14h offset

|       |         |   |   |   |   |   |   |   |
|-------|---------|---|---|---|---|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TXCOUNT |   |   |   |   |   |   |   |
| Write |         |   |   |   |   |   |   |   |
| Reset | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### UARTx\_TCFIFO field descriptions

| Field          | Description  |
|----------------|--|
| 7-0<br>TXCOUNT | <p>Transmit Counter</p> <p>The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with PFIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.</p> |

### 55.3.21 UART FIFO Receive Watermark (UARTx\_RWFIFO)

This register provides the ability to set a programmable threshold for notification of the need to remove data from the receiver FIFO/buffer. This register may be read at any time but must be written only when C2[RE] is not asserted. Changing the value in this register will not clear S1[RDRF].

Address: Base address + 15h offset

|       |         |   |   |   |   |   |   |   |
|-------|---------|---|---|---|---|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | RXWATER |   |   |   |   |   |   |   |
| Write |         |   |   |   |   |   |   |   |
| Reset | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

### UARTx\_RWFIFO field descriptions

| Field          | Description   |
|----------------|---|
| 7-0<br>RXWATER | <p>Receive Watermark</p> <p>When the number of datawords in the receive FIFO/buffer is equal to or greater than the value in this register field, an interrupt via S1[RDRF] or a DMA request via C5[RDMAS] is generated as determined by C5[RDMAS] and C2[RIE]. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by PFIFO[RXFIFOSIZE] and PFIFO[RXFE] and must be greater than 0.</p> |

### 55.3.22 UART FIFO Receive Count (UARTx\_RCFIFO)

This is a read only register that indicates how many datawords are currently in the receive FIFO/buffer. It may be read at any time.

Address: Base address + 16h offset

### UARTx\_RCFIFO field descriptions

| Field          | Description   |
|----------------|---|
| 7-0<br>RXCOUNT | <p>Receive Counter</p> <p>The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with PFIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.</p> |

### 55.3.23 UART 7816 Control Register (UARTx\_C7816)

The C7816 register is the primary control register for ISO-7816 specific functionality. This register is specific to 7816 functionality and the values in this register have no effect on UART operation and should be ignored if ISO\_7816E is not set/enabled. This register may be read at any time but values must be changed only when ISO\_7816E is not set.

Address: Base address + 18h offset

### UARTx\_C7816 field descriptions

| Field           | Description  |
|-----------------|--|
| 7-5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 4<br>ONACK      | <p>Generate NACK on Overflow</p> <p>When this field is set, the receiver automatically generates a NACK response if a receive buffer overrun occurs, as indicated by S1[OR]. In many systems, this results in the transmitter resending the packet that overflowed until the retransmit threshold for that transmitter is reached. A NACK is generated only if TTYPE=0. This field operates independently of ANACK. See . <a href="#">Overrun NACK considerations</a></p> <p>0 The received data does not generate a NACK when the receipt of the data results in an overflow event.<br/>1 If the receiver buffer overflows, a NACK is automatically sent on a received character.</p>   |
| 3<br>ANACK      | <p>Generate NACK on Error</p> <p>When this field is set, the receiver automatically generates a NACK response if a parity error occurs or if INIT is set and an invalid initial character is detected. A NACK is generated only if TTYPE = 0. If ANACK is set, the UART attempts to retransmit the data indefinitely. To stop retransmission attempts, clear C2[TE] or ISO_7816E and do not set until S1[TC] sets C2[TE] again.</p> <p>0 No NACK is automatically generated.<br/>1 A NACK is automatically generated if a parity error is detected or if an invalid initial character is detected.</p>   |
| 2<br>INIT       | <p>Detect Initial Character</p> <p>When this field is set, all received characters are searched for a valid initial character. If an invalid initial character is identified, and ANACK is set, a NACK is sent. All received data is discarded and error flags blocked (S1[NF], S1[OR], S1[FE], S1[PF], IS7816[WT], IS7816[CWT], IS7816[BWT], IS7816[GTV]) until a valid initial character is detected. Upon detecting a valid initial character, the configuration values S2[MSBF], C3[TXINV], and S2[RXINV] are automatically updated to reflect the initial character that was received. The actual INIT data value is not stored in the receive buffer. Additionally, upon detection of a valid initial character, IS7816[INITD] is set and an interrupt issued as programmed by IE7816[INITDE]. When a valid initial character is detected, INIT is automatically cleared. This Initial Character Detect feature is supported only in T = 0 protocol mode.</p> <p>0 Normal operating mode. Receiver does not seek to identify initial character.<br/>1 Receiver searches for initial character.</p> |
| 1<br>TTYPE      | <p>Transfer Type</p> <p>Indicates the transfer protocol being used.<br/>See <a href="#">ISO-7816 / smartcard support</a> for more details.</p> <p>0 T = 0 per the ISO-7816 specification.<br/>1 T = 1 per the ISO-7816 specification.</p>  |
| 0<br>ISO_7816E  | <p>ISO-7816 Functionality Enabled</p> <p>Indicates that the UART is operating according to the ISO-7816 protocol.</p> <p><b>NOTE:</b> This field must be modified only when no transmit or receive is occurring. If this field is changed during a data transfer, the data being transmitted or received may be transferred incorrectly.</p> <p>0 ISO-7816 functionality is turned off/not enabled.<br/>1 ISO-7816 functionality is turned on/enabled.</p>   |

### 55.3.24 UART 7816 Interrupt Enable Register (UARTx\_IE7816)

The IE7816 register controls which flags result in an interrupt being issued. This register is specific to 7816 functionality, the corresponding flags that drive the interrupts are not asserted when 7816E is not set/enabled. However, these flags may remain set if they are asserted while 7816E was set and not subsequently cleared. This register may be read or written to at any time.

Address: Base address + 19h offset

### 55.3.25 UART 7816 Interrupt Status Register (UARTx\_IS7816)

The IS7816 register provides a mechanism to read and clear the interrupt flags. All flags/interrupts are cleared by writing a 1 to the field location. Writing a 0 has no effect. All bits are "sticky", meaning they indicate that only the flag condition that occurred since the last time the bit was cleared, not that the condition currently exists. The status flags are set regardless of whether the corresponding field in the IE7816 is set or cleared. The IE7816 controls only if an interrupt is issued to the host processor. This register is specific to 7816 functionality and the values in this register have no affect on UART operation and should be ignored if 7816E is not set/enabled. This register may be read or written at anytime.

Address: Base address + 1Ah offset

| Bit   | 7   | 6   | 5   | 4     | 3 | 2   | 1   | 0   |
|-------|-----|-----|-----|-------|---|-----|-----|-----|

| Write | w1c | w1c | w1c | w1c   |   | w1c | w1c | w1c |
| Reset | 0   | 0   | 0   | 0     | 0 | 0   | 0   | 0   |

#### UARTx\_IS7816 field descriptions

| Field      | Description  |
|------------|--|
| 7<br>WT    | <p>Wait Timer Interrupt</p> <p>Indicates that the wait time, the time between the leading edge of a character being transmitted and the leading edge of the next response character, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 0. This interrupt is cleared by writing 1.</p> <p>0 Wait time (WT) has not been violated.<br/>1 Wait time (WT) has been violated.</p>   |
| 6<br>CWT   | <p>Character Wait Timer Interrupt</p> <p>Indicates that the character wait time, the time between the leading edges of two consecutive characters in a block, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 1. This interrupt is cleared by writing 1.</p> <p>0 Character wait time (CWT) has not been violated.<br/>1 Character wait time (CWT) has been violated.</p>  |
| 5<br>BWT   | <p>Block Wait Timer Interrupt</p> <p>Indicates that the block wait time, the time between the leading edge of first received character of a block and the leading edge of the last character the previously transmitted block, has exceeded the programmed value. This flag asserts only when C7816[TTYTYPE] = 1. This interrupt is cleared by writing 1.</p> <p>0 Block wait time (BWT) has not been violated.<br/>1 Block wait time (BWT) has been violated.</p> |
| 4<br>INITD | <p>Initial Character Detected Interrupt</p> <p>Indicates that a valid initial character is received. This interrupt is cleared by writing 1.</p>   |

Table continues on the next page...

**UARTx\_IS7816 field descriptions (continued)**

| Field         | Description   |
|---------------|---|
|               | 0 A valid initial character has not been received.<br>1 A valid initial character has been received.  |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>GTV      | Guard Timer Violated Interrupt<br><br>Indicates that one or more of the character guard time, block guard time, or guard time are violated. This interrupt is cleared by writing 1.<br><br>0 A guard time (GT, CGT, or BGT) has not been violated.<br>1 A guard time (GT, CGT, or BGT) has been violated.   |
| 1<br>TXT      | Transmit Threshold Exceeded Interrupt<br><br>Indicates that the transmit NACK threshold has been exceeded as indicated by ET7816[TXTHRESHOLD]. Regardless of whether this flag is set, the UART continues to retransmit indefinitely. This flag asserts only when C7816[TTYTYPE] = 0. If 7816E is cleared/disabled, ANACK is cleared/disabled, C2[TE] is cleared/disabled, C7816[TTYTYPE] = 1, or packet is transferred without receiving a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next received NACK. This interrupt is cleared by writing 1.<br><br>0 The number of retries and corresponding NACKS does not exceed the value in ET7816[TXTHRESHOLD].<br>1 The number of retries and corresponding NACKS exceeds the value in ET7816[TXTHRESHOLD].  |
| 0<br>RXT      | Receive Threshold Exceeded Interrupt<br><br>Indicates that there are more than ET7816[RXTHRESHOLD] consecutive NACKS generated in response to parity errors on received data. This flag requires ANACK to be set. Additionally, this flag asserts only when C7816[TTYTYPE] = 0. Clearing this field also resets the counter keeping track of consecutive NACKS. The UART will continue to attempt to receive data regardless of whether this flag is set. If 7816E is cleared/disabled, RE is cleared/disabled, C7816[TTYTYPE] = 1, or packet is received without needing to issue a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next transmitted NACK. This interrupt is cleared by writing 1.<br><br>0 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is less than or equal to the value in ET7816[RXTHRESHOLD].<br>1 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is greater than the value in ET7816[RXTHRESHOLD]. |

**55.3.26 UART 7816 Wait Parameter Register (UARTx\_WP7816T0)**

The WP7816 register contains constants used in the generation of various wait timer counters. To save register space, this register is used differently when C7816[TTYTYPE] = 0 and C7816[TTYTYPE] = 1. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Bh offset

|       |    |   |   |   |   |   |   |   |
|-------|----|---|---|---|---|---|---|---|
| Bit   | 7  | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WI |   |   |   |   |   |   |   |
| Write | WI |   |   |   |   |   |   |   |
| Reset | 0  | 0 | 0 | 0 | 1 | 0 | 1 | 0 |

### UARTx\_WP7816T0 field descriptions

| Field     | Description  |
|-----------|--|
| 7-0<br>WI | Wait Time Integer (C7816[TTYPE] = 0)<br><br>Used to calculate the value used for the WT counter. It represents a value between 1 and 255. The value of zero is not valid. This value is used only when C7816[TTYPE] = 0. See <a href="#">Wait time and guard time parameters</a> . |

### 55.3.27 UART 7816 Wait Parameter Register (UARTx\_WP7816T1)

The WP7816 register contains constants used in the generation of various wait timer counters. To save register space, this register is used differently when C7816[TTYPE] = 0 and C7816[TTYPE] = 1. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Bh offset

|       |     |   |   |   |     |   |   |   |

| Write |      |   |   |   |   |   |   |   |
| Reset | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

### UARTx\_WF7816 field descriptions

| Field       | Description   |
|-------------|---|
| 7–0<br>GTFD | FD Multiplier<br><br>Used as another multiplier in the calculation of WT and BWT. This value represents a number between 1 and 255. The value of 0 is invalid. This value is not used in baud rate generation. See <a href="#">Wait time and guard time parameters</a> and <a href="#">Baud rate generation</a> . |

### 55.3.30 UART 7816 Error Threshold Register (UARTx\_ET7816)

The ET7816 register contains fields that determine the number of NACKs that must be received or transmitted before the host processor is notified. This register may be read at anytime. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Eh offset

|       |             |   |   |   |             |   |   |   |

*Table continues on the next page...*

### UARTx\_ET7816 field descriptions (continued)

| Field              | Description  |
|--------------------|--|
|                    | <p>C7816[TTYPE] = 0 and C7816[ANACK] = 1. The value read from this field represents the number of consecutive NACKs that have been received since the last successful transmission. This counter saturates at 4'hF and does not wrap around. Regardless of how many NACKs that are received, the UART continues to retransmit indefinitely. This flag only asserts when C7816[TTYPE] = 0. For additional information see the IS7816[TXT] field description.</p> <p>0 TXT asserts on the first NACK that is received.<br/>           1 TXT asserts on the second NACK that is received.</p>   |
| 3-0<br>RXTHRESHOLD | <p>Receive NACK Threshold</p> <p>The value written to this field indicates the maximum number of consecutive NACKs generated as a result of a parity error or receiver buffer overruns before the host processor is notified. After the counter exceeds that value in the field, the IS7816[RXT] is asserted. This field is meaningful only when C7816[TTYPE] = 0. The value read from this field represents the number of consecutive NACKs that have been transmitted since the last successful reception. This counter saturates at 4'hF and does not wrap around. Regardless of the number of NACKs sent, the UART continues to receive valid packets indefinitely. For additional information, see IS7816[RXT] field description.</p> |

### 55.3.31 UART 7816 Transmit Length Register (UARTx\_TL7816)

The TL7816 register is used to indicate the number of characters contained in the block being transmitted. This register is used only when C7816[TTYPE] = 1. This register may be read at anytime. This register must be written only when C2[TE] is not enabled.

Address: Base address + 1Fh offset

|       |      |   |   |   |   |   |   |   |
|-------|------|---|---|---|---|---|---|---|
| Bit   | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TLEN |   |   |   |   |   |   |   |
| Write | TLEN |   |   |   |   |   |   |   |
| Reset | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### UARTx\_TL7816 field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>TLEN | <p>Transmit Length</p> <p>This value plus four indicates the number of characters contained in the block being transmitted. This register is automatically decremented by 1 for each character in the information field portion of the block. Additionally, this register is automatically decremented by 1 for the first character of a CRC in the epilogue field. Therefore, this register must be programmed with the number of bytes in the data packet if an LRC is being transmitted, and the number of bytes + 1 if a CRC is being transmitted. This register is not decremented for characters that are assumed to be part of the Prologue field, that is, the first three characters transmitted in a block, or the LRC or last CRC character in the Epilogue field, that is, the last character transmitted. This field must be programmed or adjusted only when C2[TE] is cleared.</p> |

### 55.3.32 UART CEA709.1-B Control Register 6 (UARTx\_C6)

Address: Base address + 21h offset

|       |       |       |    |    |   |   |   |   |
|-------|-------|-------|----|----|---|---|---|---|

| 3-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |

### 55.3.33 UART CEA709.1-B Packet Cycle Time Counter High (UARTx\_PCTH)

Address: Base address + 22h offset

|       |      |   |   |   |   |   |   |   |
|-------|------|---|---|---|---|---|---|---|
| Bit   | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | PCTH |   |   |   |   |   |   |   |
| Write |      |   |   |   |   |   |   |   |
| Reset | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### UARTx\_PCTH field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>PCTH | <p>Packet Cycle Time Counter High</p> <p>Indicates the most significant byte of maximum period after the line code violation (B1 and SDT expired) for which the bus could remain idle without decrementing back log count. If the time elapsed after line code violation (B1 and SDT expired) is greater than packet cycle time, then packet cycle timer expired interrupt is generated. It is measured in terms of bit times, that is, the time it takes for a single bit or one differential Manchester symbol to be transmitted. This is medium dependent and hence does not usually require adjustment and is programmed only once.</p> |

### 55.3.34 UART CEA709.1-B Packet Cycle Time Counter Low (UARTx\_PCTL)

Address: Base address + 23h offset

### UARTx\_PCTL field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>PCTL | <p>Packet Cycle Time Counter Low</p> <p>Indicates the least significant byte of maximum period after the line code violation (B1 and SDT expired) for which the bus could remain idle without decrementing back log count. If the time elapsed after line code violation (B1 and SDT expired) is greater than packet cycle time, then packet cycle timer expired interrupt is generated. It is measured in terms of bit times, that is, the time it takes for a single bit or one Differential Manchester symbol to be transmitted. This is medium dependent and therefore does not usually require adjustment and is programmed only once.</p> |

### 55.3.35 UART CEA709.1-B Beta1 Timer (UARTx\_B1T)

Address: Base address + 24h offset

### UARTx\_B1T field descriptions

| Field      | Description  |
|------------|--|
| 7-0<br>B1T | <p>Beta1 Timer</p> <p>Beta1 delay is a value that is system dependent and usually does not require adjustment. It is programmed only once and measured in bit times.</p> |

### 55.3.36 UART CEA709.1-B Secondary Delay Timer High (UARTx\_SDTH)

Address: Base address + 25h offset

#### UARTx\_SDTH field descriptions

| Field       | Description  |
|-------------|--|
| 7-0<br>SDTH | <p>Secondary Delay Timer High</p> <p>This is the most significant byte of the secondary delay timer and is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit or one differential Manchester symbol to be transmitted. This value must be between 0 and <math>(BL * Wbase) + (PrioritySlots - 1)</math>, Beta2 timeslots. A value of zero indicates that the queued packet will be sent immediately upon expiration of the beta1 timer.</p> |

### 55.3.37 UART CEA709.1-B Secondary Delay Timer Low (UARTx\_SDTL)

Address: Base address + 26h offset

#### UARTx\_SDTL field descriptions

| Field       | Description  |
|-------------|--|
| 7-0<br>SDTL | <p>Secondary Delay Timer Low</p> <p>This is the least significant byte of the secondary delay timer and is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit or one Differential Manchester symbol to be transmitted. This value must be between 0 and <math>(BL * Wbase) + (PrioritySlots - 1)</math>, Beta2 timeslots. A value of zero indicates that the queued packet will be sent immediately upon expiration of the Beta1 timer.</p> |

### 55.3.38 UART CEA709.1-B Preamble (UARTx\_PRE)

Address: Base address + 27h offset

### UARTx\_PRE field descriptions

| Field           | Description   |
|-----------------|---|
| 7-0<br>PREMABLE | CEA709.1-B Preamble Register<br><br>The number of bit-sync characters that occur prior to the byte-sync character when preamble is transmitted.<br><br><b>NOTE:</b> The minimum preamble length supported by twisted pair wire is four bit-sync fields. |

### 55.3.39 UART CEA709.1-B Transmit Packet Length (UARTx\_TPL)

Address: Base address + 28h offset

|       |     |   |   |   |   |   |   |   |
|-------|-----|---|---|---|---|---|---|---|
| Bit   | 7   | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TPL |   |   |   |   |   |   |   |
| Write | TPL |   |   |   |   |   |   |   |
| Reset | 0   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### UARTx\_TPL field descriptions

| Field      | Description  |
|------------|--|
| 7-0<br>TPL | Transmit Packet Length Register<br><br>Length of the data packet in bytes that is transmitted by CEA709.1-B transmitter. This includes the CRC packet as well. |

### 55.3.40 UART CEA709.1-B Interrupt Enable Register (UARTx\_IE)

Address: Base address + 29h offset

|       |   |       |       |       |       |        |      |       |

### 55.3.41 UART CEA709.1-B WBASE (UARTx\_WB)

Address: Base address + 2Ah offset

#### UARTx\_WB field descriptions

| Field        | Description               |
|--------------|---------------------------|
| 7-0<br>WBASE | CEA709.1-B WBASE register |

### UARTx\_WB field descriptions (continued)

| Field | Description   |
|-------|---|
|       | Size of the basic randomizing window in bit periods after Beta1 time period. It is measured in bit times. |

### 55.3.42 UART CEA709.1-B Status Register (UARTx\_S3)

Address: Base address + 2Bh offset

| Bit   | 7   | 6    | 5   | 4    | 3    | 2     | 1   | 0    |
|-------|-----|------|-----|------|------|-------|-----|------|
| Read  | PEF | WBEF | ISD | PRXF | PTXF | PCTEF | PSF | TXFF |
| Write | w1c | w1c  |     | w1c  | w1c  | w1c   | w1c | w1c  |
| Reset | 0   | 0    | 0   | 0    | 0    | 0     | 0   | 0    |

### UARTx\_S3 field descriptions

| Field     | Description   |
|-----------|---|
| 7<br>PEF  | <p>Preamble Error Flag</p> <p>Indicates that the received preamble has an error. If the received preamble length is greater than or less than the transmit preamble length, the preamble error flag is asserted. This flag is cleared by writing 1.</p> <p>0 Preamble is correct.<br/>1 Preamble has an error.</p>                      |
| 6<br>WBEF | <p>Wbase Expired Flag</p> <p>Indicates that the Wbase time period has expired after beta1 time slots. This flag is cleared by writing 1.</p> <p>0 WBASE time period has not expired.<br/>1 WBASE time period has expired after beta1 time slots.</p>  |
| 5<br>ISD  | <p>Initial Sync Detect</p> <p>Indicates that initially, a valid one and a line code violation is detected. This flag is cleared by deasserting EN709 bit.</p> <p>0 Initial sync is not detected.<br/>1 Initial sync is detected.</p>  |
| 4<br>PRXF | <p>Packet Received Flag</p> <p>Indicates that complete packet is received. This flag is cleared by writing 1.</p> <p>0 Packet is not received.<br/>1 Packet is received.</p>  |
| 3<br>PTXF | <p>Packet Transmitted Flag</p> <p>Indicates that complete packet is transmitted. This flag is cleared by writing 1. In case TX packet gets aborted due to FIFO becoming empty or an overflow, packet transmitted flag will still be generated.</p> <p>0 Packet transmission is not complete.<br/>1 Packet transmission is complete.</p> |

Table continues on the next page...

### UARTx\_S3 field descriptions (continued)

| Field      | Description   |
|------------|---|
| 2<br>PCTEF | <p>Packet Cycle Timer Expired Flag</p> <p>Indicates that packet cycle time period has expired with no activity on the line. This flag is cleared by writing 1.</p> <p>0 Packet cycle time has not expired.<br/>1 Packet cycle time has expired.</p>   |
| 1<br>PSF   | <p>Preamble Start Flag</p> <p>Indicates start of the preamble while the packet is being transmitted. This flag is cleared by writing 1.</p> <p>0 Preamble start is not detected.<br/>1 Preamble start is detected.</p>  |
| 0<br>TXFF  | <p>Transmission Fail Flag</p> <p>This flag indicates that transmission could not proceed. This flag is asserted when the packet is queued for transmission but before the random delay is expired an incoming receive packet is detected. This flag is also asserted while transmission when the TX fifo becomes empty or overflows. During these cases Line Code Violation is transmitted on TX line immediately after current byte or preamble transmission is finished, without waiting for completion of transmit packet length. If the transmission fail flag is asserted then TX709 bit of UART_C6 register is cleared. This flag is cleared by writing `1`.</p> <p>0 Transmission continues normally.<br/>1 Transmission has failed.</p> |

### 55.3.43 UART CEA709.1-B Status Register (UARTx\_S4)

Address: Base address + 2Ch offset

| Bit   | 7 | 6 | 5 | 4     | 3    | 2 | 1    | 0   |
|-------|---|---|---|-------|------|---|------|-----|
| Read  | 0 |   |   | INITF | CDET |   | ILCV | FE  |
| Write |   |   |   |       | w1c  |   | w1c  | w1c |
| Reset | 0 | 0 | 0 | 0     | 0    | 0 | 0    | 0   |

#### UARTx\_S4 field descriptions

| Field           | Description   |
|-----------------|---|
| 7–5<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>  |
| 4<br>INITF      | <p>Initial Synchronization Fail Flag</p> <p>Indicates that the initial synchronization has failed and the packet cycle time has expired after enabling EN709 register. This flag is cleared if EN709 is cleared.</p> <p>0 Initial synchronization has not failed.<br/>1 Initial synchronization has failed.</p> |
| 3–2<br>CDET     | CDET  |

Table continues on the next page...

### UARTx\_S4 field descriptions (continued)

| Field     | Description  |
|-----------|--|
|           | <p>Indicates when the collision occurs during transmission. This flag is cleared by writing 2'b11. If the collision flag is not cleared by software and a valid collision pulse is detected during some other phase of transmission, then collision flag continues to indicate the previous value.</p> <p>00 No collision.<br/>           01 Collision occurred during preamble.<br/>           10 Collision occurred during byte sync or data.<br/>           11 Collision occurred during line code violation.</p> |
| 1<br>ILCV | <p>Improper Line Code Violation</p> <p>Indicates that line code violation received is not proper. This flag is cleared by writing 1.</p> <p>0 Line code violation received is proper.<br/>           1 Line code violation received is improper, that is, less than three bit periods.</p>   |
| 0<br>FE   | <p>Framing Error</p> <p>Indicates that the received CEA709.1-B packet has not finished at a byte boundary. This flag is cleared by writing 1.</p> <p>0 Received packet is byte aligned.<br/>           1 Received packet is not byte aligned.</p>  |

### 55.3.44 UART CEA709.1-B Received Packet Length (UARTx\_RPL)

Address: Base address + 2Dh offset

#### UARTx\_RPL field descriptions

| Field      | Description  |
|------------|--|
| 7-0<br>RPL | <p>Received Packet Length</p> <p>Indicates the length of received packet in bytes. If the received packet is not byte aligned, the partial byte received is appended by zeros.</p> |

### 55.3.45 UART CEA709.1-B Received Preamble Length (UARTx\_RPREL)

Address: Base address + 2Eh offset

#### UARTx\_RPREL field descriptions

| Field        | Description   |
|--------------|---|
| 7-0<br>RPREL | <p>Received Preamble Length</p> <p>Indicates the number of bit sync fields received in the preamble. The length saturates to 255 for the cases where the preamble (bit sync) is larger than 255.</p> <p><b>NOTE:</b> The preamble length counter resets whenever there is no edge transition (SSSSS or DDDDD) during the resynchronization phase of preamble detection.</p> |

### 55.3.46 UART CEA709.1-B Collision Pulse Width (UARTx\_CPW)

Address: Base address + 2Fh offset

#### UARTx\_CPW field descriptions

| Field      | Description  |
|------------|--|
| 7-0<br>CPW | <p>CEA709.1-B CPW register</p> <p>Indicates the width of valid collision pulse in terms of IPG clock cycles.</p> |

### 55.3.47 UART CEA709.1-B Receive Indeterminate Time (UARTx\_RIDT)

Address: Base address + 30h offset

### UARTx\_RIDT field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>RIDT | CEA709.1-B Receive IDT register<br><br>Indicates the indeterminate time period measured in bit times after reception during which any activity on RX line will be discarded. Indeterminate time period value should be less than Beta1 timer value. |

### 55.3.48 UART CEA709.1-B Transmit Indeterminate Time (UARTx\_TIDT)

Address: Base address + 31h offset

### UARTx\_TIDT field descriptions

| Field       | Description   |
|-------------|---|
| 7-0<br>TIDT | CEA709.1-B Transmit IDT Register<br><br>This register indicates the indeterminate time period measured in bit times after transmission during which any activity on TX line will be discarded. Indeterminate time period value should be less than Beta1 timer value. |

## 55.4 Functional description

This section provides a complete functional description of the UART block.

The UART allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The UART transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the UART, writes the data to be transmitted, and processes received data.

### 55.4.1 CEA709.1-B

The UART provides support for CEA709.1-B, which is commonly used in building automation, home networking, including all key building automation subsystems such as heating, ventilating, air-conditioning, lighting, security, fire detection, access control, and energy monitoring.

### 55.4.1.1 CEA709.1-B packet cycle

The following figure illustrates the frame format and Differential Manchester encoding. Differential Manchester encoding requires that each transmitted bit includes a clock transition at the start of the bit period. This allows synchronization with the receiver.

**Figure 55-337. Frame format with differential manchester encoding**

A logic zero is indicated with the presence of a transition in the middle of the bit period and a logic one is indicated by the absence of any transition. When transitions occur at the start of the bit time, polarity is arbitrary because the last bit of a transmission has no trailing clock edge. A transmitter will transmit a preamble at the beginning of a packet to allow other nodes to synchronize their receiver clocks. The preamble comprises a bit-sync field followed by a byte-sync field. The bit-sync field is a series of differential Manchester logic ones and the byte-sync field is a single differential Manchester logic zero. The byte-sync field marks the end of the preamble and the start of the data field (MPDU/LPDU).

The transmitter terminates the packet by forcing the data output to be transitionless long enough for the receiver to recognize an invalid bit code. This signals the end of the packet. At the end of the packet transmission, the line must remain transitionless for three bit periods after the final clock transition.

The UART is responsible for providing the BitSync and ByteSync fields of the PPDU illustrated below. The layer two software manages all other encapsulating fields and provides these to the UART as part of the packet to be transmitted.

|          |           |          |          |          |      |     |
|----------|-----------|----------|----------|----------|------|-----|
| Bit Sync | Byte Sync | Priority | Alt Path | Delta BL | NPDU | CRC |
|----------|-----------|----------|----------|----------|------|-----|

**Figure 55-338. Physical protocol data unit structure**

#### NOTE

The maximum possible delay between the transmission of 3T line code violation from the end of final data bit and start of TB1T and TIDT timer is one sample clock.

### 55.4.1.2 Packet cycle and delay calculations

**Figure 55-339. CEA709.1-B packet cycle**

Predictive p-persistent CSMA is a technique for collision avoidance that randomizes channel access using knowledge of predicted load. It manages software using data and events reported by the hardware.

Beta1 delay is a value set by the software. It is generally a fixed value that is system dependent and hence does not usually require adjustment. It is measured in bit times, that is, the time that it takes for a single bit to be transmitted or one differential Manchester symbol. Beta1 is defined by CEA/EIA-709 specification as:

$$\text{Beta1} > 1 \text{ bit time} + (2 \times T_{\text{aup}} + T_{\text{aum}})$$

Where  $T_{\text{aup}}$  is the physical propagation delay defined by the media length.

$T_{\text{aum}}$  is the detection and turn around-delay within the MAC sublayer; this is the period from the time the idle channel condition is detected, to the point when the first output transition appears on the output. On media where there is a carrier, this time must include the time between turning on the carrier, and it being asserted as a valid carrier on the medium.

The secondary delay timer is a value that is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit to be transmitted or one differential Manchester symbol. This value must be between 0 and  $(\text{BL} \times \text{Wbase}) + (\text{PrioritySlots} - 1)$ , Beta2 timeslots. A value of zero indicates that the queued packet for transmit is to be sent immediately upon expiration of the beta1 timer. According to the CEA/EIA-709 specification:

- BL is back log
- Wbase is 16 beta2 timeslots
- A priorityslot is the same amount of time as a beta2 timeslot
- $\text{Beta2} > 2 \times T_{\text{aup}} + T_{\text{aum}}$

Priority slots are handled completely by software. When calculating the secondary delay timer value, the software must take into account any priority slot that is included in the design of the system.

Each node must maintain an estimation of the current channel backlog. Backlog calculation is managed by the layer two software. Initially, the backlog is set to one. The backlog is incremented on transmission by a value indicated in the frames backlog increment field.

The backlog decrements under the following conditions:

- On waiting to transmit: If Wbase randomizing slots go by without channel activity.
- On receive: If a packet is received with a backlog increment of 0.
- On transmit: If a packet is transmitted with a backlog increment of 0.
- On idle: If a packet cycle time expires without channel activity.

The following actions need to be completed when a frame is received to prepare an outgoing message for transmission after the channel becomes idle:

- CRC of incoming message needs to be verified by software.
- If the CRC is good, the BL is recalculated, otherwise BL remains the same.
- Transmit delay (secondary delay timer) is calculated and supplied to UART.

### 55.4.1.3 Clock resynchronization

The UART is transmitting on time base source. Therefore, all receivers keep synchronizing with the node that is transmitting and no clock resynchronization occurs in transmitting.

When the UART is receiving or waiting to transmit, clock resynchronization is vital. Because long streams of data are possible (up to 229 bytes + headers), there exists significant potential for nodes to wander regarding time reference over the course of the message. Therefore, Differential Manchester Encoding (DME) is used. While DME requires twice the bandwidth of non-return to zero (NRZ) encoding schemes, it has the benefit of a guaranteed transition at the start of each bit transmitter. A transition occurring at the middle of the bit is encoded as a logic 0 or the lack of a transition at the middle of the bit time is encoded as a logic 1. By detecting the transition at the start of a bit period, the receiver is able to be resynthesized to the transmitter every bit period. Resynchronization can occur only after the node is already synchronized with the system. Additionally, for resynchronization to be effective, some basic assumptions regarding the system must be made:

1. Only a single channel sample may be in error (noise) over the entire bit (16 samples) period.
2. While a node is drifted from the system time base, with the resynchronization, the node is never shifted by more than 2 data samples in a given bit period.
3. If multiple noise events have occurred, no action is taken.

**functional description**

4. If a single noise event occurs, and it is possible to uniquely identify the noise event, then resynchronization takes place.

Starting at sample 15 of the previous time bit period, five data samples are collected. The number and location of the samples are key to decide if an adjustment in time base is required. Table below lists the possible values and the actions associated with each possibility. In the table, S means the data is the same as the logical value that was received in the second half of the previous bit period. D means that the sample is different from the logical value that was received in the second half of the previous bit period.

| Sample Values (15,16,1,2,3) | Action / Event  |
|-----------------------------|---|
| SSSSS                       | No start of bit transition has been detected. Hence no adjustment to time base is made.   |
| SSSSD                       | Two or more error events occurred or the time base was off. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.   |
| SSSDS                       | Either two (or more) error events occurred, time base were off along with noise occurrence or sample 2 is noise and there is no start of bit transition. Hence no adjustment to time base is made.  |
| SSSDD                       | It is possible that either noise was received during sample 1 or the time base needs shifting. In this case, the time base is slowed down by one. Sample 2 becomes sample 1, and sample 3 becomes sample 2. The next sample is treated as sample 3. |
| SSDSS                       | It is most likely that sample 1 is noise and there is no start of bit transition. Hence no adjustment to time base is made.   |
| SSDSD                       | It is possible that sample 1 is noise, and time base needs shifting by two, or that sample 2 is noise. It is more likely that sample 2 is noise and therefore no adjustment to time base is made.   |
| SSDDS                       | It is most likely that sample 3 is noise. Therefore, no adjustment to time base is made.  |
| SSDDD                       | This is the expected case. Therefore, no adjustment to time base is made.   |
| SDSSS                       | It is most likely that sample 16 is noise and there is no start of bit transition, hence no adjustment to time base is made.  |
| SDSSD                       | Either multiple errors occurred or sample 16 is noise and time base is off by two. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.  |
| SDSDS                       | In this case multiple errors have occurred. Hence no adjustment to time base is made.   |
| SDSDD                       | In this case, there must either be multiple noise or one noise (at sample 16 or sample 1) with a time shift. Assuming that one noise occurred, it unclear what direction the time shift is. Hence no adjustment to time base is made.               |

*Table continues on the next page...*

| Sample Values (15,16,1,2,3) | Action / Event  |
|-----------------------------|---|
| SDDSS                       | In this case either multiple errors occurred, two (or more) noise or two (or more) noise and a time shift. The most likely case is that samples 16 and 1 are noise. Hence no adjustment to time base is made.   |
| SDDSD                       | The most likely case is noise for sample 2 and a time shift. Therefore, the time base is sped up by one. Sample 16 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5.  |
| SDDDS                       | The most likely case is noise for sample 3 and a time shift. Therefore, the time base is sped up by one. Sample 16 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5.  |
| SDDDD                       | Either sample 16 is noise or the time base has shifted. In this case, it is assumed that a time shift has occurred. Therefore, the time base is sped up by one. Sample 15 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5. |
| DSSSS                       | It is most likely that sample 16 is noise and there is no start of bit transition, hence no adjustment to time base is made.  |
| DSSSD                       | It is most likely that sample 15 is noise along with time shift. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.  |
| DSSDS                       | In this case multiple errors occurred. Hence no adjustment to time base is made.  |
| DSSDD                       | Either multiple errors occurred, possibly with time shift, or sample 15 is noise. In this case, the time base is slowed down by one. Sample 2 becomes sample 1, and sample 3 becomes sample 2. The next sample is treated as sample 3.  |
| DSDSS                       | In this case multiple errors occurred. Hence no adjustment to time base is made.  |
| DSDDSD                      | In this case, multiple errors occurred. Therefore, no adjustment to time base is made.  |
| DSDDDS                      | In this case, multiple errors occurred. Therefore, no adjustment to time base is made.  |
| DSDDDD                      | In this case, either multiple errors occurred or sample 15 is noise and there is no start of bit transition. Therefore, no adjustment to time base is made.   |
| DDSSS                       | In this case multiple errors occurred. It is most likely that samples 15 and 16 are noise. Hence no adjustment to time base is made.  |
| DDSSD                       | In this case multiple errors occurred. Hence no adjustment to time base is made.  |
| DDSDS                       | In this case multiple errors occurred. Hence no adjustment to time base is made.  |

Table continues on the next page...

| Sample Values (15,16,1,2,3) | Action / Event  |
|-----------------------------|---|
| DDSDD                       | It is most likely that sample 1 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.                         |
| DDDSS                       | In this case multiple errors occurred along with time shift. Hence no adjustment to time base is made.  |
| DDSD                        | It is most likely that sample 2 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.                         |
| DDDDS                       | It is most likely that sample 3 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.                         |
| DDDDD                       | Either samples 15 and 16 are noise or the time base has shifted. Therefore, the time base is speed up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6. |

### 55.4.1.4 Data sampling

The receiver samples the unsynchronized receiver input signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock is resynchronized after every bit.

To locate the start of preamble, data recovery logic does an asynchronous search for a valid edge, logic 0 preceded by two logic 1s or logic 1 preceded by two logic 0s. When the falling edge or rising edge of a possible preamble bit occurs, the RT clock begins to count to 16.

Figure 55-340. Receiver data sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT4, and RT5. The following table summarizes the results of the preamble verification samples.

**Table 55-347. Preamble/ Data bit verification**

| RT3, RT4, and RT5 samples | Preamble verification |
|---------------------------|-----------------------|
| 000                       | Yes                   |
| 001                       | Yes                   |
| 010                       | Yes                   |
| 011                       | No                    |
| 100                       | Yes                   |
| 101                       | No                    |
| 110                       | No                    |
| 111                       | No                    |

If preamble verification is not successful, the RT clock is reset and a new search for a preamble begins.

To determine the value of a data bit, recovery logic takes samples at RT11, RT12, and RT13. The following table summarizes the results of the data bit samples. If the majority of RT11, RT12, and RT13 samples is the same as the majority of RT3, RT4, and RT5 samples, then the data bit detected is 1, else the data bit detected is 0.

**Table 55-348. Data bit recovery**

| RT11, RT12, and RT13 samples | Data bit determination |
|------------------------------|------------------------|
| 000                          | 0                      |
| 001                          | 0                      |
| 010                          | 0                      |
| 011                          | 1                      |
| 100                          | 0                      |
| 101                          | 1                      |
| 110                          | 1                      |
| 111                          | 1                      |

To signify the end of a data packet, the transmitter causes a line-code violation to occur, that is, the transmitter remains transitionless for at least 3-bit periods after the final clock transition, excluding the final data transition, if it exists. The receiver detects this violation. For the purpose of detecting a line-code violation, the receiver monitors the channel to locate a series of five or six back-to-back half bit periods.

### 55.4.1.5 Initial clock synchronization

When operating with EN709 set, there are various times when initial clock synchronization is required. When the UART has just been enabled, there is clearly no system clock reference. Additionally, if a channel has remained idle for a significant period of time, such as the arbitration time between packets, substantial clock drift may have occurred in the system between nodes. This is because there have been meaningful clock transitions on the channel to keep nodes synchronized. After these events, the clock may require significant synchronization adjustment; this event is referred to as initial clock synchronization.

There are three situations that may occur when a node attempts to obtain initial clock synchronization.

1. The node enters the system while a data packet is being actively transmitted.
2. The node enters the system while there is no data packet being actively transmitted on the system.
3. The node is already in the system and initial clock synchronization is required due to the end of a packet.

For case 1 and 2, the UART implements the following procedure:

1. The UART attempts to identify a valid line code violation. The line code violation is detected if the LCV counter reached the programmed value (default 20). The LCV counter resets automatically whenever valid edge is identified. Valid edge is identified if there is a transition in samples i.e. 0->1(sample1) or 1->0(sample1), and the subsequent two samples are equal (i.e sample 1 and sample 2) and sample 1 is not equal to the majority of previous 3 samples with respect to sample 1.
2. If the required line-code violation is detected, the beta1 delay timer will start and the UART will transit to case 3. Until then the UART will not be able to receive nor transmit any packet.

For case 3, it implements the following procedure:

1. Beta1 delay and secondary delay times increment as appropriate, that is Beta1 delay expires before the secondary delay timer starts.
2. While the timers are counting, the UART attempts to identify a valid edge.
3. If a valid receive edge is identified after the appropriate IDT has expired (RIDT or TIDT), but before the SDT expires and data is queued to be transmitted (C6[TX709] set), the transmission will be aborted before starting and the incoming data packet will be received. The S3[TXFF] flag will set to indicate that the transmission did not start.

4. If a valid edge is not identified before the delay time expires, and data is queued to be transmitted, the UART considers itself synchronized, and starts the preamble process.
5. If a valid edge is not identified before the delay time expires, and data is not queued to be transmitted, the UART continues attempting to locate a valid edge using the same process, and receives the incoming data packet like in step 3.

### 55.4.1.6 Priority packet preemption

The first data is fetched from the data buffer immediately after the preamble has completed. Therefore, it is possible to decide which data is sent during transmission until the completion of the preamble. This can be done in two different ways.

- The expected data to be transmitted can be written to the data buffer before or shortly after TE is enabled. In this case, the data is ready before the start of the preamble period. If a high priority packet has been identified for immediate/preemptive transmission, software may flush the data buffer and put the new data into the data buffer. This new data must be put into the data buffer prior to the completion of the preamble. Similarly, the transmit packet length register needs to be updated.
- Software can trigger data to be transmitted by asserting TE before the actual data has been placed in the data buffer. In the end, the software can write data into the data

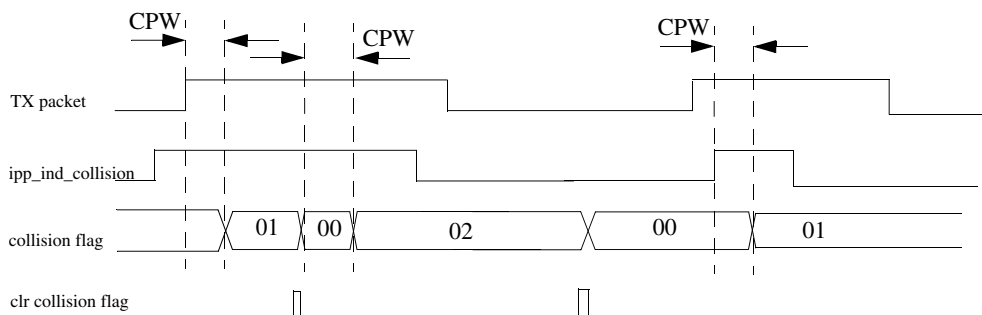

buffer and update the transmit packet length register. This occurs before the preamble completes. To assist in identifying how much time is left before the preamble completes, the preamble started interrupt is asserted when the UART starts transmitting the preamble.

**NOTE**

1. If the data buffer does not contain at least one byte of valid data and the transmit packet length register has been updated prior to the preamble completing, an underflow event will occur and TXEN is deasserted. The packet is terminated by transmitting line code violation.
2. The maximum possible delay between masking the RX ( due to LON FSM entering into TX State) and the first transmit preamble edge is 1 bit time while OBE is asserted with no delay with respect to masking of RX line.

**55.4.1.7 Collision detection**

Collision flag is detected only when device is transmitting if C6[CE] is asserted. The collision pulse is valid if it is asserted for CPW number of peripheral clock cycles. If the collision signal is already asserted before the start of packet transmission, then the width of the collision pulse is calculated from the start of transmit packet as shown in the figure below. If the collision signal is not cleared by the software by writing 11b, then the flag continues to retain the previous value. After the flag is cleared, the collision pulse width is calculated again, and the flag is asserted, if the width is equal to or more than the programmed CPW value.

**Figure 55-341. Collision pulse detection**

The collision signal is asynchronous to the ipg clk, therefore the collision pulse of width exactly equal to CPW may not be detected correctly due to synchronization issue. The collision pulse visible to design may be decreased by one peripheral clock cycle due to the asynchronous nature of the collision pulse.

## 55.4.2 Transmitter

Figure 55-342. Transmitter Block Diagram

### 55.4.2.1 Transmitter character length

The UART transmitter can accommodate either 8, 9, or 10-bit data characters. The state of the **C1[M]** and **C1[PE]** bits and the **C4[M10]** bit determine the length of data characters. When transmitting 9-bit data, bit **C3[T8]** is the ninth bit (bit 8).

### 55.4.2.2 Transmission bit order

When S2[MSBF] is set, the UART automatically transmits the MSB of the data word as the first bit after the start bit. Similarly, the LSB of the data word is transmitted immediately preceding the parity bit, or the stop bit if parity is not enabled. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data written to D for transmission is completely independent of the S2[MSBF] setting.

### 55.4.2.3 Character transmission

To transmit data, the MCU writes the data bits to the UART transmit buffer using UART data registers C3[T8] and D. Data in the transmit buffer is then transferred to the transmitter shift register as needed. The transmit shift register then shifts a frame out through the transmit data output signal after it has prefaced it with any required start and stop bits. The UART data registers, C3[T8] and D, provide access to the transmit buffer structure.

The UART also sets a flag, the transmit data register empty flag S1[TDRE], and generates an interrupt or DMA request (C5[TDMAS]) whenever the number of datawords in the transmit buffer is equal to or less than the value indicated by TWFIFO[TXWATER]. The transmit driver routine may respond to this flag by writing additional datawords to the transmit buffer using C3[T8]/D as space permits.

See [Application information](#) for specific programming sequences.

Setting C2[TE] automatically loads the transmit shift register with the following preamble:

- 10 logic 1s if C1[M] = 0
- 11 logic 1s if C1[M] = 1 and C4[M10] = 0
- 12 logic 1s if C1[M] = 1, C4[M10] = 1, C1[PE] = 1

After the preamble shifts out, control logic transfers the data from the D register into the transmit shift register. The transmitter automatically transmits the correct start bit and stop bit before and after the dataword.

When C7816[ISO\_7816E] = 1, setting C2[TE] does not result in a preamble being generated. The transmitter starts transmitting as soon as the corresponding guard time expires. When C7816[TTYPER] = 0, the value in GT is used. When C7816[TTYPER] = 1, the value in BGT is used, because C2[TE] will remain asserted until the end of the block transfer. C2[TE] is automatically cleared when C7816[TTYPER] = 1 and the block being transmitted has completed. When C7816[TTYPER] = 0, the transmitter listens for a NACK indication. If no NACK is received, it is assumed that the character was correctly

received. If a NACK is received, the transmitter resends the data, assuming that the number of retries for that character, that is, the number of NACKs received, is less than or equal to the value in ET7816[TXTHRESHOLD].

Hardware supports odd or even parity. When parity is enabled, the bit immediately preceding the stop bit is the parity bit.

When the transmit shift register is not transmitting a frame, the transmit data output signal goes to the idle condition, logic 1. If at any time software clears C2[TE], the transmitter enable signal goes low and the transmit signal goes idle.

If the software clears C2[TE] while a transmission is in progress, the character in the transmit shift register continues to shift out, provided S1[TC] was cleared during the data write sequence. To clear S1[TC], the S1 register must be read followed by a write to D register.

If S1[TC] is cleared during character transmission and C2[TE] is cleared, the transmission enable signal is deasserted at the completion of the current frame. Following this, the transmit data out signal enters the idle state even if there is data pending in the UART transmit data buffer. To ensure that all the data written in the FIFO is transmitted on the link before clearing C2[TE], wait for S1[TC] to set. Alternatively, the same can be achieved by setting TWFIFO[TXWATER] to 0x0 and waiting for S1[TDRE] to set.

#### 55.4.2.4 Transmitting break characters

Setting C2[SBK] loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on C1[M], C1[PE], S2[BRK13] and C4[M10]. See the following table.

**Table 55-349. Transmit break character length**

| S2[BRK13] | C1[M] | C4[M10] | C1[PE] | Bits transmitted |
|-----------|-------|---------|--------|------------------|
| 0         | 0     | —       | —      | 10               |
| 0         | 1     | 1       | 0      | 11               |
| 0         | 1     | 1       | 1      | 12               |
| 1         | 0     | —       | —      | 13               |
| 1         | 1     | —       | —      | 14               |

As long as C2[SBK] is set, the transmitter logic continuously loads break characters into the transmit shift register. After the software clears C2[SBK], the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character. Break bits are not supported when C7816[ISO\_7816E] is set/enabled.

## NOTE

When queuing a break character, it will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that, if data is queued in the data buffer to be transmitted, the break character preempts that queued data. The queued data is then transmitted after the break character is complete.

### 55.4.2.5 Idle characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on C1[M], C1[PE] and C4[M10]. The preamble is a synchronizing idle character that begins the first transmission initiated after setting C2[TE]. When C7816[ISO\_7816E] is set/enabled, idle characters are not sent or detected. When data is not being transmitted, the data I/O line is in an inactive state.

If C2[TE] is cleared during a transmission, the transmit data output signal becomes idle after completion of the transmission in progress. Clearing and then setting C2[TE] during a transmission queues an idle character to be sent after the dataword currently being transmitted.

## Note

When queuing an idle character, the idle character will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that if data is queued in the data buffer to be transmitted, the idle character preempts that queued data. The queued data is then transmitted after the idle character is complete.

If C2[TE] is cleared and the transmission is completed, the UART is not the master of the TXD pin.

### 55.4.2.6 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS. If the clear-to-send operation is enabled, the character is transmitted when CTS is asserted. If CTS is deasserted in the middle of a transmission with characters remaining in the receiver data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS is reasserted.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS. Also, if the transmitter is forced to send a continuous low condition because it is sending a break character, the transmitter ignores the state of CTS regardless of whether the clear-to-send operation is enabled.

The transmitter's CTS signal can also be enabled even if the same UART receiver's RTS signal is disabled.

### 55.4.2.7 Transceiver driver enable

The transmitter can use RTS as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using RTS](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS asserts one bit time before the start bit is transmitted. RTS remains asserted for the whole time that the transmitter data buffer has any characters. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS signal asserts only when the transmitter is enabled. However, the transmitter's RTS signal is unaffected by its CTS signal. RTS will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

The following figure shows the functional timing information for the transmitter. Along with the actual character itself, TXD shows the start bit. The stop bit is also indicated, with a dashed line if necessary.

1. Cn = transmit characters

**Figure 55-343. Transmitter RTS and CTS timing diagram**

## 55.4.3 Receiver

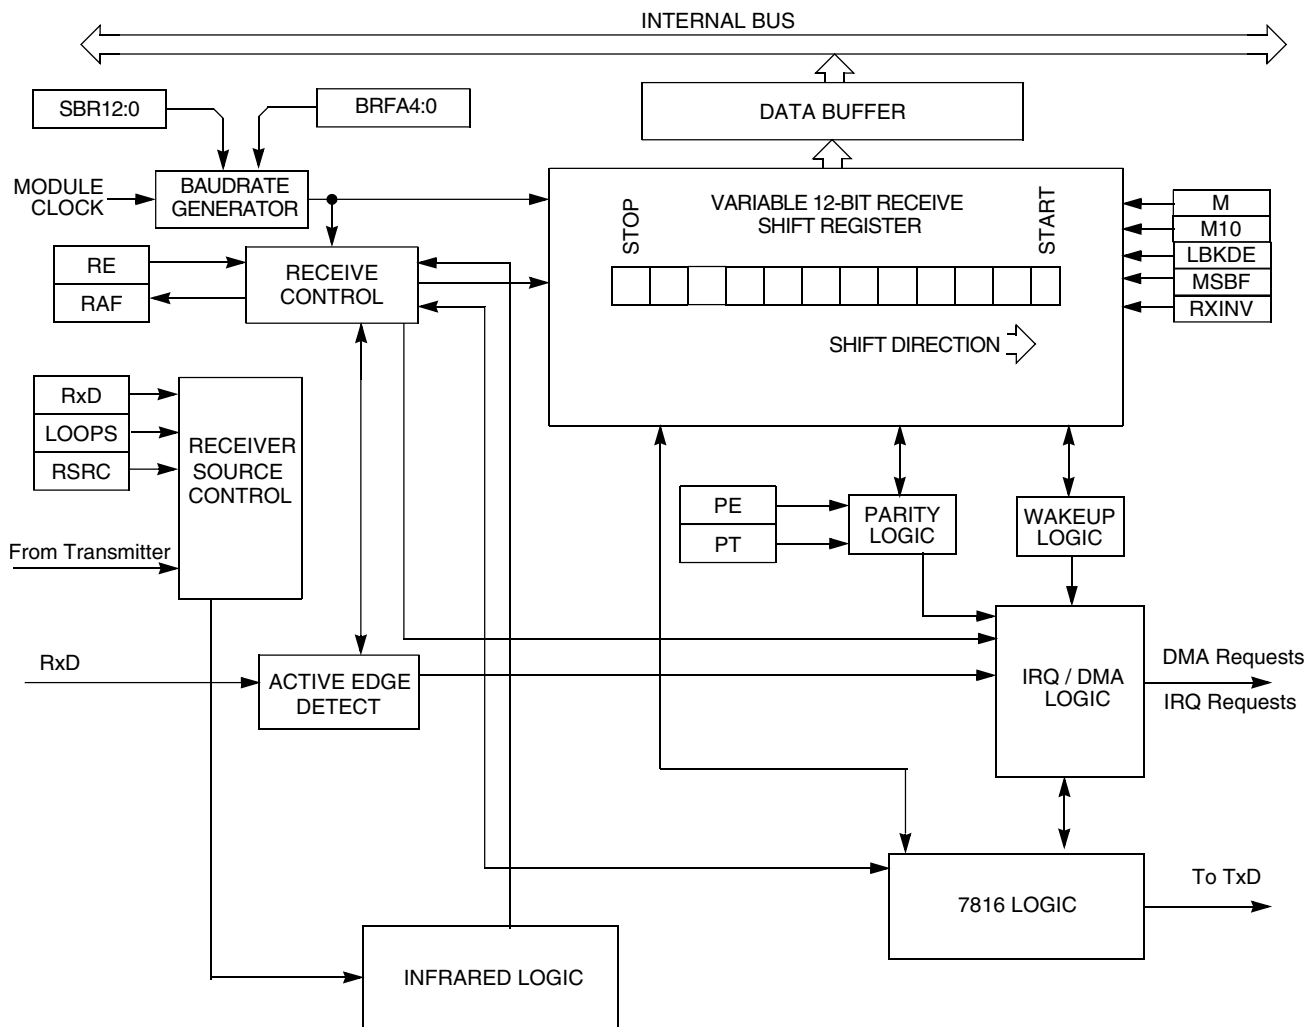

Figure 55-344. UART receiver block diagram

### 55.4.3.1 Receiver character length

The UART receiver can accommodate 8-, 9-, or 10-bit data characters. The states of C1[M], C1[PE] and C4[M10] determine the length of data characters. When receiving 9 or 10-bit data, C3[R8] is the ninth bit (bit 8).

### 55.4.3.2 Receiver bit ordering

When S2[MSBF] is set, the receiver operates such that the first bit received after the start bit is the MSB of the dataword. Similarly, the bit received immediately preceding the parity bit, or the stop bit if parity is not enabled, is treated as the LSB for the dataword. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data read from receive data buffer is completely independent of S2[MSBF].

### 55.4.3.3 Character reception

During UART reception, the receive shift register shifts a frame in from the unsynchronized receiver input signal. After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the UART receive buffer. Additionally, the noise and parity error flags that are calculated during the receive process are also captured in the UART receive buffer. The receive data buffer is accessible via the D and C3[T8] registers. Additional received information flags regarding the receive dataword can be read in ED register. S1[RDRF] is set if the number of resulting datawords in the receive buffer is equal to or greater than the number indicated by RWFIFO[RXWATER]. If the C2[RIE] is also set, RDRF generates an RDRF interrupt request. Alternatively, by programming C5[RDMAS], a DMA request can be generated.

When C7816[ISO\_7816E] is set/enabled and C7816[TTYTYPE] = 0, character reception operates slightly differently. Upon receipt of the parity bit, the validity of the parity bit is checked. If C7816[ANACK] is set and the parity check fails, or if INIT and the received character is not a valid initial character, then a NACK is sent by the receiver. If the number of consecutive receive errors exceeds the threshold set by ET7816[RXTHRESHOLD], then IS7816[RXT] is set and an interrupt generated if IE7816[RXTE] is set. If an error is detected due to parity or an invalid initial character, the data is not transferred from the receive shift register to the receive buffer. Instead, the data is overwritten by the next incoming data.

When the C7816[ISO\_7816E] is set/enabled, C7816[ONACK] is set/enabled, and the received character results in the receive buffer overflowing, a NACK is issued by the receiver. Additionally, S1[OR] is set and an interrupt is issued if required, and the data in the shift register is discarded.

### 55.4.3.4 Framing errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, S1[FE], if S2[LBKDE] is disabled. When S2[LBKDE] is disabled, a break character also sets the S1[FE] because a break character

has no stop bit. S1[FE] is set at the same time that received data is placed in the receive data buffer. Framing errors are not supported when C7816[ISO7816E] is set/enabled. However, if S1[FE] is set, data will not be received when C7816[ISO7816E] is set.

### 55.4.3.5 Receiving break characters

The UART recognizes a break character when a start bit is followed by eight, nine, or ten logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on UART registers:

- Sets the framing error flag, S1[FE].
- Writes an all 0 dataword to the data buffer, which may cause S1[RDRF] to set, depending on the watermark and number of values in the data buffer.
- May set the overrun flag, S1[OR], noise flag, S1[NF], parity error flag, S1[PE], or the receiver active flag, S2[RAF].

The detection threshold for a break character can be adjusted when using an internal oscillator in a LIN system by setting S2[LBKDE]. The UART break character detection threshold depends on C1[M], C1[PE], S2[LBKDE] and C4[M10]. See the following table.

**Table 55-350. Receive break character detection threshold**

| LBKDE | M | M10 | PE | Threshold (bits) |
|-------|---|-----|----|------------------|
| 0     | 0 | —   | —  | 10               |
| 0     | 1 | 0   | —  | 11               |
| 0     | 1 | 1   | 1  | 12               |
| 1     | 0 | —   | —  | 11               |
| 1     | 1 | —   | —  | 12               |

While S2[LBKDE] is set, it will have these effects on the UART registers:

- Prevents S1[RDRF], S1[FE], S1[NF], and S1[PF] from being set. However, if they are already set, they will remain set.
- Sets the LIN break detect interrupt flag, S2[LBKDIF], if a LIN break character is received.

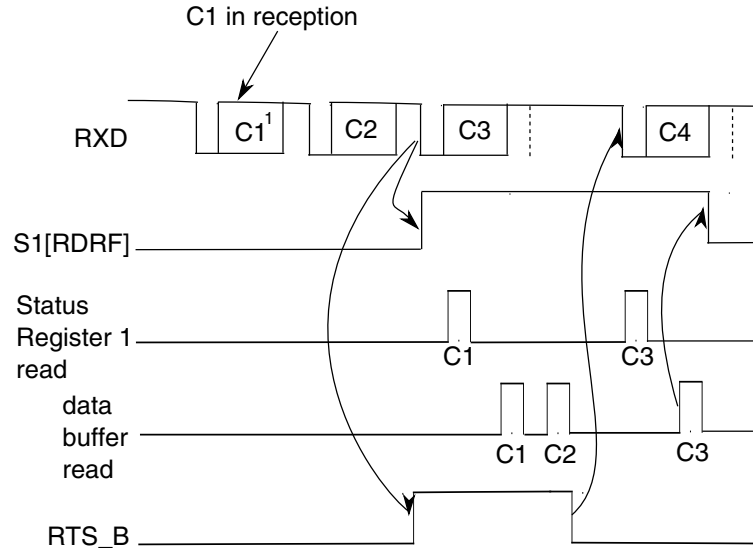

Break characters are not detected or supported when C7816[ISO\_7816E] is set/enabled.

### 55.4.3.6 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS.

- RTS remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using RTS](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS if the number of characters in the receiver data register is equal to or greater than receiver data buffer's watermark, RWFIFO[RXWATER].
- The receiver asserts RTS when the number of characters in the receiver data register is less than the watermark. It is not affected if RDRF is asserted.
- Even if RTS is deasserted, the receiver continues to receive characters until the receiver data buffer is full or is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS remains deasserted.

The following figure shows receiver hardware flow control functional timing. Along with the actual character itself, RXD shows the start bit. The stop bit can also indicated, with a dashed line, if necessary. The watermark is set to 2.

**Figure 55-345. Receiver hardware flow control timing diagram**

### 55.4.3.7 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a 16-RT clock counter that filters noise and indicates when a 1 is received.

#### 55.4.3.7.1 Start bit detection

When S2[RXINV] is cleared, the first rising edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 55.4.3.7.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one RT clocks can be undetected by it regardless of whether it is seen in the first or second half of the count.

#### 55.4.3.7.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

#### 55.4.3.7.4 High-bit detection

At 16-RT clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

### 55.4.3.8 Baud rate tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the

RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic 0.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

### 55.4.3.8.1 Slow data tolerance

The following figure shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

**Figure 55-346. Slow data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 55-346](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 147 RT cycles (9 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) \div 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 55-346](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 163 RT cycles (10 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) \div 170) \times 100 = 4.12\%$$

### 55.4.3.8.2 Fast data tolerance

The following figure shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

**Figure 55-347. Fast data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 55-347](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 160 RT cycles (10 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) \div 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 55-347](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 176 RT cycles (11 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) \div 170) \times 100 = 3.53\%$$

### 55.4.3.9 Receiver wakeup

C1[WAKE] determines how the UART is brought out of the standby state to process an incoming message. C1[WAKE] enables either idle line wakeup or address mark wakeup.

Receiver wakeup is not supported when C7816[ISO\_7816E] is set/enabled because multi-receiver systems are not allowed.

### 55.4.3.9.1 Idle input line wakeup (C1[WAKE] = 0)

In this wakeup method, an idle condition on the unsynchronized receiver input signal clears C2[RWU] and wakes the UART. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another idle character appears on the unsynchronized receiver input signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

When C2[RWU] is 1 and S2[RWUID] is 0, the idle character that wakes the receiver does not set S1[IDLE] or the receive data register full flag, S1[RDRF]. The receiver wakes and waits for the first data character of the next message which is stored in the receive data buffer. When S2[RWUID] and C2[RWU] are set and C1[WAKE] is cleared, any idle condition sets S1[IDLE] and generates an interrupt if enabled.

Idle input line wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

### 55.4.3.9.2 Address mark wakeup (C1[WAKE] = 1)

In this wakeup method, a logic 1 in the bit position immediately preceding the stop bit of a frame clears C2[RWU] and wakes the UART. A logic 1 in the bit position immediately preceding the stop bit marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another address frame appears on the unsynchronized receiver input signal.

A logic 1 in the bit position immediately preceding the stop bit clears the receiver's C2[RWU] after the stop bit is received and places the received data into the receiver data buffer. Note that if Match Address operation is enabled i.e. C4[MAEN1] or C4[MAEN2] is set, then received frame is transferred to receive buffer only if the comparison matches.

Address mark wakeup allows messages to contain idle characters but requires that the bit position immediately preceding the stop bit be reserved for use in address frames.

If module is in standby mode and nothing triggers to wake the UART, no error flag is set even if an invalid error condition is detected on the receiving data line.

Address mark wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

### 55.4.3.9.3 Match address operation

Match address operation is enabled when C4[MAEN1] or C4[MAEN2] is set. In this function, a frame received by the RX pin with a logic 1 in the bit position of the address mark is considered an address and is compared with the associated MA1 or MA2 register. The frame is transferred to the receive buffer, and S1[RDRF] is set, only if the comparison matches. All subsequent frames received with a logic 0 in the bit position of the address mark are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs, then no transfer is made to the receive data buffer, and all following frames with logic 0 in the bit position of the address mark are also discarded. If both C4[MAEN1] and C4[MAEN2] are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Match address operation functions in the same way for both MA1 and MA2 registers. Note that the position of the address mark is the same as the Parity Bit when parity is enabled for 8 bit and 9 bit data formats.

- If only one of C4[MAEN1] and C4[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If C4[MAEN1] and C4[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

Address match operation is not supported when C7816[ISO\_7816E] is set/enabled.

### 55.4.4 Baud rate generation

A 13-bit modulus counter and a 5-bit fractional fine-adjust counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the module clock divisor. The SBR bits are in the UART baud rate registers, BDH and BDL. The baud rate clock is synchronized with the module clock and drives the receiver. The fractional fine-adjust counter adds fractional delays to the baud rate clock to allow fine trimming of the baud rate to match the system baud rate. The transmitter is driven by the baud rate clock divided by 16. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to two sources of error:

**functional description**

- Integer division of the module clock may not give the exact target frequency. This error can be reduced with the fine-adjust counter.
- Synchronization with the module clock can cause phase shift.

The [Table 55-351](#) lists the available baud divisor fine adjust values.

$$\text{UART baud rate} = \text{UART module clock} / (16 \times (\text{SBR}[12:0] + \text{BRFD}))$$

The following table lists some examples of achieving target baud rates with a module clock frequency of 10.2 MHz, with and without fractional fine adjustment.

**Table 55-351. Baud rates (example: module clock = 10.2 MHz)**

| Bits SBR (decimal) | Bits BRFA | BRFD value    | Receiver clock (Hz) | Transmitter clock (Hz) | Target Baud rate | Error (%) |
|--------------------|-----------|---------------|---------------------|------------------------|------------------|-----------|
| 17                 | 00000     | 0             | 600,000.0           | 37,500.0               | 38,400           | 2.3       |

| 1 1 1 1 1 | 31/32 = 0.96875                     |

## 55.4.5 Data format (non ISO-7816)

Each data character is contained in a frame that includes a start bit and a stop bit. The rest of the data format depends upon C1[M], C1[PE], S2[MSBF] and C4[M10].

### 55.4.5.1 Eight-bit configuration

Clearing C1[M] configures the UART for 8-bit data characters, that is, eight bits are memory mapped in D. A frame with eight data bits has a total of 10 bits. The most significant bit of the eight data bits can be used as an address mark to wake the receiver. If the most significant bit is used in this way, then it serves as an address or data indication, leaving the remaining seven bits as actual data. When C1[PE] is set, the eighth data bit is automatically calculated as the parity bit. See the following table.

**Table 55-353. Configuration of 8-bit data format**

| UART_C1[PE] | Start bit | Data bits | Address bits   | Parity bits | Stop bit |
|-------------|-----------|-----------|----------------|-------------|----------|
| 0           | 1         | 8         | 0              | 0           | 1        |
| 0           | 1         | 7         | 1 <sup>1</sup> | 0           | 1        |
| 1           | 1         | 7         | 0              | 1           | 1        |

1. The address bit identifies the frame as an address character. See [Receiver wakeup](#).

### 55.4.5.2 Nine-bit configuration

When C1[M] is set and C4[M10] is cleared, the UART is configured for 9-bit data characters. If C1[PE] is enabled, the ninth bit is either C3[T8/R8] or the internally generated parity bit. This results in a frame consisting of a total of 11 bits. In the event that the ninth data bit is selected to be C3[T8], it will remain unchanged after transmission and can be used repeatedly without rewriting it, unless the value needs to be changed. This feature may be useful when the ninth data bit is being used as an address mark.

When C1[M] and C4[M10] are set, the UART is configured for 9-bit data characters, but the frame consists of a total of 12 bits. The 12 bits include the start and stop bits, the 9 data character bits, and a tenth internal data bit. Note that if C4[M10] is set, C1[PE] must also be set. In this case, the tenth bit is the internally generated parity bit. The ninth bit can either be used as an address mark or a ninth data bit.

See the following table.

**Table 55-354. Configuration of 9-bit data formats**

| C1[PE] | UC1[M] | C1[M10] | Start bit                                   | Data bits | Address bits   | Parity bits | Stop bit |
|--------|--------|---------|---|-----------|----------------|-------------|----------|
| 0      | 0      | 0       | See <a href="#">Eight-bit configuration</a> |           |                |             |          |
| 0      | 0      | 1       | Invalid configuration                       |           |                |             |          |
| 0      | 1      | 0       | 1   | 9         | 0              | 0           | 1        |
| 0      | 1      | 0       | 1   | 8         | 1 <sup>1</sup> | 0           | 1        |
| 0      | 1      | 1       | Invalid Configuration                       |           |                |             |          |
| 1      | 0      | 0       | See <a href="#">Eight-bit configuration</a> |           |                |             |          |
| 1      | 0      | 1       | Invalid Configuration                       |           |                |             |          |
| 1      | 1      | 0       | 1   | 8         | 0              | 1           | 1        |
| 1      | 1      | 1       | 1   | 9         | 0              | 1           | 1        |
| 1      | 1      | 1       | 1   | 8         | 1 <sup>2</sup> | 1           | 1        |

1. The address bit identifies the frame as an address character.

2. The address bit identifies the frame as an address character.

### Note

Unless in 9-bit mode with M10 set, do not use address mark wakeup with parity enabled.

## 55.4.5.3 Timing examples

Timing examples of these configurations in the NRZ mark/space data format are illustrated in the following figures. The timing examples show all of the configurations in the following sub-sections along with the LSB and MSB first variations.

### 55.4.5.3.1 Eight-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

Figure 55-348. Eight bits of data with LSB first

Figure 55-349. Eight bits of data with MSB first

### 55.4.5.3.2 Eight-bit format with parity enabled

Figure 55-350. Seven bits of data with LSB first and parity

Figure 55-351. Seven bits of data with MSB first and parity

### 55.4.5.3.3 Nine-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

Figure 55-352. Nine bits of data with LSB first

**Figure 55-353. Nine bits of data with MSB first**

### 55.4.5.3.4 Nine-bit format with parity enabled

**Figure 55-354. Eight bits of data with LSB first and parity**

**Figure 55-355. Eight bits of data with MSB first and parity**

### 55.4.5.3.5 Non-memory mapped tenth bit for parity

The most significant memory-mapped bit can be used for address mark wakeup.

**Figure 55-356. Nine bits of data with LSB first and parity**

**Figure 55-357. Nine bits of data with MSB first and parity**

## 55.4.6 Single-wire operation

Normally, the UART uses two pins for transmitting and receiving. In single wire operation, the RXD pin is disconnected from the UART and the UART implements a half-duplex serial connection. The UART uses the TXD pin for both receiving and transmitting.

**Figure 55-358. Single-wire operation (C1[LOOPS] = 1, C1[RSRC] = 1)**

Enable single wire operation by setting C1[LOOPS] and the receiver source field, C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Setting C1[RSRC] connects the receiver input to the output of the TXD pin driver. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 55.4.7 Loop operation

In loop operation, the transmitter output goes to the receiver input. The unsynchronized receiver input signal is disconnected from the UART.

**Figure 55-359. Loop operation (C1[LOOPS] = 1, C1[RSRC] = 0)**

Enable loop operation by setting C1[LOOPS] and clearing C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Clearing C1[RSRC] connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 55.4.8 ISO-7816/smartcard support

The UART provides mechanisms to support the ISO-7816 protocol that is commonly used to interface with smartcards. The ISO-7816 protocol is an NRZ, single wire, half-duplex interface. The TxD pin is used in open-drain mode because the data signal is used for both transmitting and receiving. There are multiple subprotocols within the ISO-7816 standard. The UART supports both T = 0 and T = 1 protocols. The module also provides for automated initial character detection and configuration, which allows for support of both direct convention and inverse convention data formats. A variety of interrupts specific to 7816 are provided in addition to the general interrupts to assist software. Additionally, the module is able to provide automated NACK responses and has programmed automated retransmission of failed packets. An assortment of programmable timeouts and guard band times are also supported.

The term elemental time unit (ETU) is frequently used in the context of ISO-7816. This concept is used to relate the frequency that the system (UART) is running at and the frequency that data is being transmitted and received. One ETU represents the time it takes to transmit or receive a single bit. For example, a standard 7816 packet, excluding any guard time or NACK elements is 10 ETUs (start bit, 8 data bits, and a parity bit). Guard times and wait times are also measured in ETUs.,

**NOTE**

The ISO-7816 specification may have certain configuration options that are reserved. To maintain maximum flexibility to support future 7816 enhancements or devices that may not strictly conform to the specification, the UART does not prevent those options being used. Further, the UART may provide configuration options that exceed the flexibility of options explicitly allowed by the 7816 specification. Failure to correctly configure the UART may result in unexpected behavior or incompatibility with the ISO-7816 specification.

**55.4.8.1 Initial characters**

In ISO-7816 with T = 0 mode, the UART can be configured to use C7816[INIT] to detect the next valid initial character, referred to by the ISO-7816 specifically as a TS character. When the initial character is detected, the UART provides the host processor with an interrupt if IE7816[INITDE] is set. Additionally, the UART will alter S2[MSBF], C3[TXINV], and S2[RXINV] automatically, based on the initial character. The corresponding initial character and resulting register settings are listed in the following table.

**Table 55-355. Initial character automated settings**

| Initial character (bit 1-10)       | Initial character (hex) | MSBF | TXINV | RXINV |
|------------------------------------|-------------------------|------|-------|-------|
| LHHL LLL LLH<br>inverse convention | 3F                      | 1    | 1     | 1     |
| LHHL HHH LLH<br>direct convention  | 3B                      | 0    | 0     | 0     |

S2[MSBF], C3[TXINV], and S2[RXINV] must be reset to their default values before C7816[INIT] is set. Once C7816[INIT] is set, the receiver searches all received data for the first valid initial character. Detecting a Direct Convention Initial Character will cause no change to S2[MSBF], C3[TXINV], and S2[RXINV], while detecting an Inverse Convention Initial Character will cause these fields to set automatically. All data

received, which is not a valid initial character, is ignored and all flags resulting from the invalid data are blocked from asserting. If C7816[ANACK] is set, a NACK is returned for invalid received initial characters and an RXT interrupt is generated as programmed.

### 55.4.8.2 Protocol T = 0

When T = 0 protocol is selected, a relatively complex error detection scheme is used. Data characters are formatted as illustrated in the following figure. This scheme is also used for answer to reset and Peripheral Pin Select (PPS) formats.

**Figure 55-360. ISO-7816 T = 0 data format**

As with other protocols supported by the UART, the data character includes a start bit. However, in this case, there are two stop bits rather than the typical single stop bit. In addition to a standard even parity check, the receiver has the ability to generate and return a NACK during the second half of the first stop bit period. The NACK must be at least one time period (ETU) in length and no more than two time periods (ETU) in length. The transmitter must wait for at least two time units (ETU) after detection of the error signal before attempting to retransmit the character.

It is assumed that the UART and the device (smartcard) know in advance which device is receiving and which is transmitting. No special mechanism is supplied by the UART to control receive and transmit in the mode other than C2[TE] and C2[RE]. Initial Character Detect feature is also supported in this mode.

### 55.4.8.3 Protocol T = 1

When T = 1 protocol is selected, the NACK error detection scheme is not used. Rather, the parity bit is used on a character basis and a CRC or LRC is used on the block basis, that is, for each group of characters. In this mode, the data format allows for a single stop bit although additional inactive bit periods may be present between the stop bit and the next start bit. Data characters are formatted as illustrated in the following figure.

ISO 7816 FORMAT (T=1)

**Figure 55-361. ISO 7816 T=1 data format**

The smallest data unit that is transferred is a block. A block is made up of several data characters and may vary in size depending on the block type. The UART does not provide a mechanism to decode the block type. As part of the block, an LRC or CRC is included. The UART does not calculate the CRC or LRC for transmitted blocks, nor does it verify the validity of the CRC or LRC for received blocks. The 7816 protocol requires that the initiator and the smartcard (device) takes alternate turns in transmitting and receiving blocks. When the UART detects that the last character in a block has been transmitted it will automatically clear C2[TE], C3[TXDIR] and enter receive mode. Therefore, the software must program the transmit buffer with the next data to be transmitted and then enable C2[TE] and set C3[TXDIR], once the software has determined that the last character of the received block has been received. The UART detects that the last character of the transmit block has been sent when TL7816[TLEN] = 0 and four additional characters have been sent. The four additional characters are made up of three prior to TL7816[TLEN] decrementing (prologue) and one after TL7816[TLEN] = 0, the final character of the epilogue.

#### 55.4.8.4 Wait time and guard time parameters

The ISO-7816 specification defines several wait time and guard time parameters. The UART allows for flexible configuration and violation detection of these settings. On reset, the wait time (IS7816[WT]) defaults to 9600 ETUs and guard time (GT) to 12 ETUs. These values are controlled by parameters in the WP7816, WN7816, and WF7816 registers. Additionally, the value of C7816[TTYPER] also factors into the calculation. The formulae used to calculate the number ETUs for each wait time and guard time value are shown in [Table 55-356](#).

Wait time (WT) is defined as the maximum allowable time between the leading edge of a character transmitted by the smartcard device and the leading edge of the previous character that was transmitted by the UART or the device. Similarly, character wait time (CWT) is defined as the maximum allowable time between the leading edge of two characters within the same block. Block wait time (BWT) is defined as the maximum time between the leading edge character of the last block received by the smartcard device and the leading edge of the first character transmitted by the smartcard device.

Guard time (GT) is defined as the minimum allowable time between the leading edge of two consecutive characters. Character guard time (CGT) is the minimum allowable time between the leading edges of two consecutive characters in the same direction, that is,

transmission or reception. Block guard time (BGT) is the minimum allowable time between the leading edges of two consecutive characters in opposite directions, that is, transmission then reception or reception then transmission.

The GT and WT counters reset whenever  $C7816[TTYTYPE] = 1$  or  $C7816[ISO\_7816E] = 0$  or a new dataword start bit has been received or transmitted as specified by the counter descriptions. The CWT, CGT, BWT, BGT counters reset whenever  $C7816[TTYTYPE] = 0$  or  $C7816[ISO\_7816E] = 0$  or a new dataword start bit is received or transmitted as specified by the counter descriptions. When  $C7816[TTYTYPE] = 1$ , some of the counter values require an assumption regarding the first data transferred when the UART first starts. This assumption is required when the 7816E is disabled, when transition from  $C7816[TTYTYPE] = 0$  to  $C7816[TTYTYPE] = 1$  or when coming out of reset. In this case, it is assumed that the previous non-existent transfer was a received transfer.

The UART will automatically handle GT, CGT, and BGT such that the UART will not send a packet before the corresponding guard time expiring.

**Table 55-356. Wait and guard time calculations**

| Parameter                  | Reset value [ETU] | $C7816[TTYTYPE] = 0$<br>[ETU]  | $C7816[TTYTYPE] = 1$<br>[ETU]  |
|----------------------------|-------------------|--|--|
| Wait time (WT)             | 9600              | $((WI + 1) \times 960 \times (GTFD + 1)) - 1$                              | Not used   |
| Character wait time (CWT)  | Not used          | Not used   | $11 + 2^{(CWI - 1)}$   |
| Block wait time (BWT)      | Not used          | Not used   | $10 + 2^{BWI} \times 960 \times (GTFD + 1)$                                |
| Guard time (GT)            | 12                | <b>GTN not equal to 255</b><br>$12 + GTN$<br><b>GTN equal to 255</b><br>12 | Not used   |
| Character guard time (CGT) | Not used          | Not used   | <b>GTN not equal to 255</b><br>$12 + GTN$<br><b>GTN equal to 255</b><br>11 |
| Block guard time (BGT)     | Not used          | Not used   | 22   |

### 55.4.8.5 Baud rate generation

The value in  $WF7816[GTFD]$  does not impact the clock frequency. SBR and BRFD are used to generate the clock frequency. This clock frequency is used by the UART only and is not seen by the smartcard device. The transmitter clocks operates at 1/16 the frequency of the receive clock so that the receiver is able to sample the received value 16 times during the ETU.

### 55.4.8.6 UART restrictions in ISO-7816 operation

Due to the flexibility of the UART module, there are several features and interrupts that are not supported while running in ISO-7816 mode. These restrictions are documented within the register field definitions.

### 55.4.9 Infrared interface

The UART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the UART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This design covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The UART has an infrared transmit encoder and receive decoder. The UART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the MCU. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the UART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active low pulses.

The infrared submodule receives its clock sources from the UART. One of these two clocks are selected in the infrared submodule to generate either 3/16, 1/16, 1/32, or 1/4 narrow pulses during transmission.

#### 55.4.9.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle of the bit with a duration of 1/32, 1/16, 3/16, or 1/4 of a bit time. A narrow high pulse is transmitted for a zero bit when C3[TXINV] is cleared, while a narrow low pulse is transmitted for a zero bit when C3[TXINV] is set.

### 55.4.9.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow high pulse is expected for a zero bit when S2[RXINV] is cleared, while a narrow low pulse is expected for a zero bit when S2[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

## 55.5 Reset

All registers reset to a particular value are indicated in [Memory map and registers](#).

## 55.6 System level interrupt sources

There are several interrupt signals that are sent from the UART. The following table lists the interrupt sources generated by the UART. The local enables for the UART interrupt sources are described in this table. Details regarding the individual operation of each interrupt are contained under various sub-sections of [Memory map and registers](#). However, [RXEDGIF description](#) also outlines additional details regarding the RXEDGIF interrupt because of its complexity of operation. Any of the UART interrupt requests listed in the table can be used to bring the CPU out of Wait mode.

**Table 55-357. UART interrupt sources**

| Interrupt Source | Flag    | Local enable | DMA select |
|------------------|---------|--------------|------------|
| Transmitter      | TDRE    | TIE          | TDMAS = 0  |
| Transmitter      | TC      | TCIE         | -          |
| Receiver         | IDLE    | ILIE         | -          |
| Receiver         | RDRF    | RIE          | RDMAS = 0  |
| Receiver         | LBKDIF  | LBKDIE       | -          |
| Receiver         | RXEDGIF | RXEDGIE      | -          |
| Receiver         | OR      | ORIE         | -          |
| Receiver         | NF      | NEIE         | -          |
| Receiver         | FE      | FEIE         | -          |
| Receiver         | PF      | PEIE         | -          |
| Receiver         | RXUF    | RXUFE        | -          |
| Transmitter      | TXOF    | TXOFE        | -          |
| Receiver         | WT      | WTWE         | -          |
| Receiver         | CWT     | CWTE         | -          |

*Table continues on the next page...*

**Table 55-357. UART interrupt sources (continued)**

| Interrupt Source | Flag  | Local enable | DMA select |
|------------------|-------|--------------|------------|
| Receiver         | BWT   | BWTE         | -          |
| Receiver         | INITD | INITDE       | -          |
| Receiver         | TXT   | TXTE         | -          |
| Receiver         | RXT   | RXTE         | -          |
| Receiver         | GTV   | GTVE         | -          |

## 55.6.1 RXEDGIF description

S2[RXEDGIF] is set when an active edge is detected on the RxD pin. Therefore, the active edge can be detected only when in two wire mode. A RXEDGIF interrupt is generated only when S2[RXEDGIF] is set. If RXEDGIE is not enabled before S2[RXEDGIF] is set, an interrupt is not generated.

### 55.6.1.1 RxD edge detect sensitivity

Edge sensitivity can be software programmed to be either falling or rising. The polarity of the edge sensitivity is selected using S2[RXINV]. To detect the falling edge, S2[RXINV] is programmed to 0. To detect the rising edge, S2[RXINV] is programmed to 1.

Synchronizing logic is used prior to detect edges. Prior to detecting an edge, the receive data on RxD input must be at the deasserted logic level. A falling edge is detected when the RxD input signal is seen as a logic 1 (the deasserted level) during one module clock cycle, and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input is seen as a logic 0 during one module clock cycle and then a logic 1 during the next cycle.

### 55.6.1.2 Clearing RXEDGIF interrupt request

Writing a logic 1 to S2[RXEDGIF] immediately clears the RXEDGIF interrupt request even if the RxD input remains asserted. S2[RXEDGIF] remains set if another active edge is detected on RxD while attempting to clear S2[RXEDGIF] by writing a 1 to it.

### 55.6.1.3 Exit from low-power modes

The receive input active edge detect circuit is still active on low power modes (Wait and Stop). An active edge on the receive input brings the CPU out of low power mode if the interrupt is not masked ( $S2[RXEDGIF] = 1$ ).

## 55.7 DMA operation

In the transmitter,  $S1[TDRE]$  can be configured to assert a DMA transfer request. In the receiver,  $S1[RDRF]$ , can be configured to assert a DMA transfer request. The following table shows the configuration field settings required to configure each flag for DMA operation.

**Table 55-358. DMA configuration**

| Flag | Request enable bit | DMA select bit |
|------|--------------------|----------------|
| TDRE | TIE = 1            | TDMAS = 1      |
| RDRF | RIE = 1            | RDMAS = 1      |

When a flag is configured for a DMA request, its associated DMA request is asserted when the flag is set. When  $S1[RDRF]$  is configured as a DMA request, the clearing mechanism of reading  $S1$ , followed by reading  $D$ , does not clear the associated flag. The DMA request remains asserted until an indication is received that the DMA transactions are done. When this indication is received, the flag bit and the associated DMA request is cleared. If the DMA operation failed to remove the situation that caused the DMA request, another request is issued.

## 55.8 Application information

This section describes the UART application information.

### 55.8.1 Transmit/receive data buffer operation

The UART has independent receive and transmit buffers. The size of these buffers may vary depending on the implementation of the module. The implemented size of the buffers is a fixed constant via  $PFIFO[TXFIFOSIZE]$  and  $PFIFO[RXFIFOSIZE]$ . Additionally, legacy support is provided that allows for the FIFO structure to operate as a

depth of one. This is the default/reset behavior of the module and can be adjusted using the PFIFO[RXFE] and PFIFO[TXFE] bits. Individual watermark levels are also provided for transmit and receive.

There are multiple ways to ensure that a data block, which is a set of characters, has completed transmission. These methods include:

1. Set TXFIFO[TXWATER] to 0. TDRE asserts when there is no further data in the transmit buffer. Alternatively the S1[TC] flag can be used to indicate when the transmit shift register is also empty.
2. Poll TCFIFO[TXCOUNT]. Assuming that only data for a data block has been put into the data buffer, when TCFIFO[TXCOUNT] = 0, all data has been transmitted or is in the process of transmission.
3. S1[TC] can be monitored. When S1[TC] asserts, it indicates that all data has been transmitted and there is no data currently being transmitted in the shift register.

## 55.8.2 ISO-7816 initialization sequence

This section outlines how to program the UART for ISO-7816 operation. Elements such as procedures to power up or power down the smartcard, and when to take those actions, are beyond the scope of this description. To set up the UART for ISO-7816 operation:

1. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL. According to the 7816 specification the initial (default) baud rating setting should be  $F_i = 372$  and  $D_i = 1$  and a maximum frequency of 5 MHz. In other words, the BDH, BDL, and C4 registers should be programmed such that the transmission frequency provided to the smartcard device must be  $1/372$ th of the clock and must not exceed 5 MHz.
2. Write to set BDH[LBKDIE] = 0.
3. Write to C1 to configure word length, parity, and other configuration fields (LOOPS, RSRC) and set C1[M] = 1, C1[PE] = 1, and C1[PT] = 0.
4. Write to set S2[RWUID] = 0 and S2[LBKDE] = 0.
5. Write to set MODEM[RXRTSE] = 0, MODEM[TXRTSPOL] = 0, MODEM[TXRTSE] = 0, and MODEM[TXCTSE] = 0.

6. Write to set up interrupt enable fields desired (C3[ORIE], C3[NEIE], C3[PEIE], and C3[FEIE])
7. Write to set C4[MAEN1] = 0 and C4[MAEN2] = 0.
8. Write to C5 register and configure DMA control register fields as desired for application.
9. Write to set C7816[INIT] = 1, C7816[TTYTYPE] = 0, and C7816[ISO\_7816E] = 1. Program C7816[ONACK] and C7816[ANACK] as desired.
10. Write to IE7816 to set interrupt enable parameters as desired.
11. Write to ET7816 and set as desired.
12. Write to set C2[ILIE] = 0, C2[RE] = 1, C2[TE] = 1, C2[RWU] = 0, and C2[SBK] = 0. Set up interrupt enables C2[TIE], C2[TCIE], and C2[RIE] as desired.

At this time, the UART will start listening for an initial character. After being identified, it will automatically adjust S2[MSBF], C3[TXINV], and S2[RXINV]. The software must then receive and process an answer to reset. Upon processing the answer to reset, the software must write to set C2[RE] = 0 and C2[TE] = 0. The software should then adjust 7816 specific and UART generic parameters to match and configure data that was received during the answer on reset period. After the new settings have been programmed, including the new baud rate and C7816[TTYTYPE], C2[RE] and C2[TE] can be reenabled as required.

### 55.8.2.1 Transmission procedure for (C7816[TTYTYPE] = 0)

When the protocol selected is C7816[TTYTYPE] = 0, it is assumed that the software has a prior knowledge of who should be transmitting and receiving. Therefore, no mechanism is provided for automated transmission/receipt control. The software must monitor S1[TDRE], or configure for an interrupt, and provide additional data for transmission, as appropriate. Additionally, software should set C2[TE] = 1 and control TXDIR whenever it is the UART's turn to transmit information. For ease of monitoring, it is suggested that only data be transmitted until the next receiver/transmit switchover is loaded into the transmit FIFO/buffer.

### 55.8.2.2 Transmission procedure for (C7816[TTYPE] = 1)

When the protocol selected is C7816[TTYPE] = 1, data is transferred in blocks. Before starting a transmission, the software must write the size, in number of bytes, for the Information Field portion of the block into TLEN. If a CRC is being transmitted for the block, the value in TLEN must be one more than the size of the information field. The software must then set C2[TE] = 1 and C2[RE] = 1. The software must then monitor S1[TDRE]/interrupt and write the prologue, information, and epilogue field to the transmit buffer. TLEN automatically decrements, except for prologue bytes and the final epilogue byte. When the final epilogue byte has been transmitted, the UART automatically clears C2[TE] and C3[TXDIR] to 0, and the UART automatically starts capturing the response to the block that was transmitted. After the software has detected the receipt of the response, the transmission process must be repeated as needed with sufficient urgency to ensure that the block wait time and character wait times are not violated.

### 55.8.3 Initialization sequence (non ISO-7816)

To initiate a UART transmission:

1. Configure the UART.
  - a. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL.
  - b. Write to C1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, and PT). Write to C4, MA1, and MA2 to configure.
  - c. Enable the transmitter, interrupts, receiver, and wakeup as required, by writing to C2 (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK), S2 (MSBF and BRK13), and C3 (ORIE, NEIE, PEIE, and FEIE). A preamble or idle character is then shifted out of the transmitter shift register.
2. Transmit procedure for each byte.
  - a. Monitor S1[TDRE] by reading S1 or responding to the TDRE interrupt. The amount of free space in the transmit buffer directly using TCFIFO[TXCOUNT] can also be monitored.

- b. If the TDRE flag is set, or there is space in the transmit buffer, write the data to be transmitted to (C3[T8]/D). A new transmission will not result until data exists in the transmit buffer.
3. Repeat step 2 for each subsequent transmission.

### Note

During normal operation, S1[TDRE] is set when the shift register is loaded with the next data to be transmitted from the transmit buffer and the number of datawords contained in the transmit buffer is less than or equal to the value in TWFIFO[TXWATER]. This occurs 9/16ths of a bit time after the start of the stop bit of the previous frame.

To separate messages with preambles with minimum idle line time, use this sequence between messages.

1. Write the last dataword of the first message to C3[T8]/D.
2. Wait for S1[TDRE] to go high with TWFIFO[TXWATER] = 0, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting C2[TE].
4. Write the first and subsequent datawords of the second message to C3[T8]/D.

## 55.8.4 Overrun (OR) flag implications

To be flexible, the overrun flag (OR) operates slightly differently depending on the mode of operation. There may be implications that need to be carefully considered. This section clarifies the behavior and the resulting implications. Regardless of mode, if a dataword is received while S1[OR] is set, S1[RDRF] and S1[IDLE] are blocked from asserting. If S1[RDRF] or S1[IDLE] were previously asserted, they will remain asserted until cleared.

### 55.8.4.1 Overrun operation

The assertion of S1[OR] indicates that a significant event has occurred. The assertion indicates that received data has been lost because there was a lack of room to store it in the data buffer. Therefore, while S1[OR] is set, no further data is stored in the data buffer until S1[OR] is cleared. This ensures that the application will be able to handle the overrun condition.

In most applications, because the total amount of lost data is known, the application will attempt to return the system to a known state. Before S1[OR] is cleared, all received data will be dropped. For this, the software does the following.

1. Remove data from the receive data buffer. This could be done by reading data from the data buffer and processing it if the data in the FIFO was still valuable when the overrun event occurred, or using CFIFO[RXFLUSH] to clear the buffer.
2. Clear S1[OR]. Note that if data was cleared using CFIFO[RXFLUSH], then clearing S1[OR] will result in SFIFO[RXUF] asserting. This is because the only way to clear S1[OR] requires reading additional information from the FIFO. Care should be taken to disable the SFIFO[RXUF] interrupt prior to clearing the OR flag and then clearing SFIFO[RXUF] after the OR flag has been cleared.

Note that, in some applications, if an overrun event is responded to fast enough, the lost data can be recovered. For example, when C7816[ISO\_7816E] is asserted, C7816[TTYTYPE]=1 and C7816[ONACK] = 1, the application may reasonably be able to determine whether the lost data will be resent by the device. In this scenario, flushing the receiver data buffer may not be required. Rather, if S1[OR] is cleared, the lost data may be resent and therefore may be recoverable.

When LIN break detect (LBKDE) is asserted, S1[OR] has significantly different behavior than in other modes. S1[OR] will be set, regardless of how much space is actually available in the data buffer, if a LIN break character has been detected and the corresponding flag, S2[LBKDIF], is not cleared before the first data character is received after S2[LBKDIF] asserted. This behavior is intended to allow the software sufficient time to read the LIN break character from the data buffer to ensure that a break character was actually detected. The checking of the break character was used on some older implementations and is therefore supported for legacy reasons. Applications that do not require this checking can simply clear S2[LBKDIF] without checking the stored value to ensure it is a break character.

## 55.8.5 Overrun NACK considerations

When C7816[ISO\_7816E] is enabled and C7816[TTYTYPE] = 0, the retransmission feature of the 7816 protocol can be used to help avoid lost data when the data buffer overflows. Using C7816[ONACK], the module can be programmed to issue a NACK on an overflow event. Assuming that the smartcard device has implemented retransmission, the lost data will be retransmitted. While useful, there is a programming implication that may require special consideration. The need to transmit a NACK must be determined and committed to prior to the dataword being fully received. While the NACK is being received, it is possible that the application code will read the data buffer such that

sufficient room will be made to store the dataword that is being NACK'ed. Even if room has been made in the data buffer after the transmission of a NACK is completed, the received data will always be discarded as a result of an overflow and the ET7816[RXTHRESHOLD] value will be incremented by one. However, if sufficient space now exists to write the received data which was NACK'ed, S1[OR] will be blocked and kept from asserting.

### 55.8.6 Match address registers

The two match address registers allow a second match address function for a broadcast or general call address to the serial bus, as an example.

### 55.8.7 Modem feature

This section describes the modem features.

#### 55.8.7.1 Ready-to-receive using RTS

To help to stop overrun of the receiver data buffer, the RTS signal can be used by the receiver to indicate to another UART that it is ready to receive data. The other UART can send the data when its CTS signal is asserted. This handshaking conforms to the TIA-232-E standard. A transceiver is necessary if the required voltage levels of the communication link do not match the voltage levels of the UART's RTS and CTS signals.

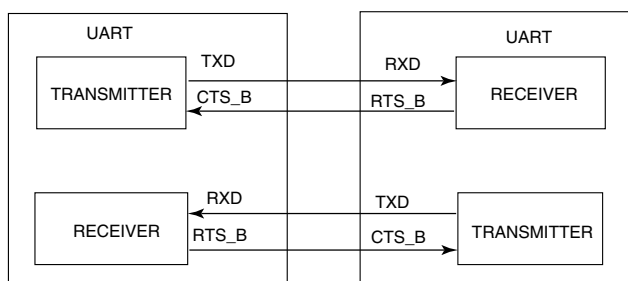

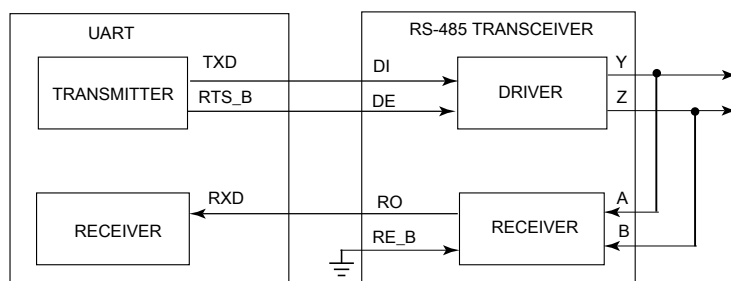

Figure 55-362. Ready-to-receive

The transmitter's CTS signal can be used for hardware flow control whether its RTS signal is used for hardware flow control, transceiver driver enable, or not at all.

### 55.8.7.2 Transceiver driver enable using RTS

RS-485 is a multiple drop communication protocol in which the UART transceiver's driver is 3-stated unless the UART is driving. The RTS signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS can be matched to the polarity of the transceiver's driver enable signal. See the following figure.

**Figure 55-363. Transceiver driver enable using RTS**

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS\_B to both DE and RE\_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the UART in single wire mode, freeing the RXD pin for other uses.

### 55.8.8 IrDA minimum pulse width

The IrDA specifies a minimum pulse width of 1.6  $\mu$ s. The UART hardware does not include a mechanism to restrict/force the pulse width to be greater than or equal to 1.6  $\mu$ s. However, configuring the baud rate to 115.2 kbit/s and the narrow pulse width to 3/16 of a bit time results in a pulse width of 1.6  $\mu$ s.

### 55.8.9 Clearing 7816 wait timer (WT, BWT, CWT) interrupts

The 7816 wait timer interrupts associated with IS7816[WT], IS7816[BWT], and IS7816[CWT] will automatically reassert if they are cleared and the wait time is still violated. This behavior is similar to most of the other interrupts on the UART. In most cases, if the condition that caused the interrupt to trigger still exists when the interrupt is cleared, then the interrupt will reassert. For example, consider the following scenario:

1. IS7816[WT] is programmed to assert after 9600 cycles of unresponsiveness.
2. The 9600 cycles pass without a response resulting in the WT interrupt asserting.
3. The IS7816[WT] is cleared at cycle 9700 by the interrupt service routine.

4. After the WT interrupt has been cleared, the smartcard remains unresponsive. At cycle 9701 the WT interrupt will be reasserted.

If the intent of clearing the interrupt is such that it does not reassert, the interrupt service routine must remove or clear the condition that originally caused the interrupt to assert prior to clearing the interrupt. There are multiple ways that this can be accomplished, including ensuring that an event that results in the wait timer resetting occurs, such as, the transmission of another packet.

### 55.8.10 Legacy and reverse compatibility considerations

Recent versions of the UART have added several new features. Whenever reasonably possible, reverse compatibility was maintained. However, in some cases this was either not feasible or the behavior was deemed as not intended. This section describes several differences to legacy operation that resulted from these recent enhancements. If application code from previous versions is used, it must be reviewed and modified to take the following items into account. Depending on the application code, additional items that are not listed here may also need to be considered.

1. Various reserved registers and register bits are used, such as, MSFB and M10.
2. This module now generates an error when invalid address spaces are used.
3. While documentation indicated otherwise, in some cases it was possible for S1[IDLE] to assert even if S1[OR] was set.
4. S1[OR] will be set only if the data buffer (FIFO) does not have sufficient room. Previously, the data buffer was always a fixed size of one and the S1[OR] flag would set so long as S1[RDRF] was set even if there was room in the data buffer. While the clearing mechanism has remained the same for S1[RDRF], keeping the OR flag assertion tied to the RDRF event rather than the data buffer being full would have greatly reduced the usefulness of the buffer when its size is larger than one.
5. Previously, when C2[RWU] was set (and WAKE = 0), the IDLE flag could reassert up to every bit period causing an interrupt and requiring the host processor to reassert C2[RWU]. This behavior has been modified. Now, when C2[RWU] is set (and WAKE = 0), at least one non-idle bit must be detected before an idle can be detected.

# Chapter 56

## Secured digital host controller (SDHC)

### 56.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The chapter is intended for a module driver software developer. It describes module-level operation and programming.

### 56.2 Overview

#### 56.2.1 Supported types of cards

Different types of cards supported by the SDHC are described briefly as follows:

The multimedia card (MMC) is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The secure digital card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC with some additions.

Under the SD protocol, it can be categorized into memory card, I/O card and combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the figure does not show cards with reduced size or mini cards.

**Figure 56-1. System connection of the SDHC**

CE-ATA is a hard drive interface that is optimized for embedded applications storage. The device is layered on the top of the MMC protocol stack using the same physical interface. The interface electrical and signaling definition is defined like that in the MMC specification. See the CE-ATA specification for more details.

## 56.2.2 SDHC block diagram

Figure 56-2. Enhanced secure digital host controller block diagram

## 56.2.3 Features

The features of the SDHC module include:

- Conforms to the SD Host Controller Standard Specification version 2.0 including test event register support
- Compatible with the MMC System Specification version 4.2/4.3
- Compatible with the SD Memory Card Specification version 2.0 and supports the high capacity SD memory card
- Compatible with the SDIO Card Specification version 2.0
- Compatible with the CE-ATA Card Specification version 1.0

- Designed to work with CE-ATA, SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 52 MHz
- Supports 1-bit/4-bit SD and SDIO modes, 1-bit/4-bit / 8-bit MMC modes, 1-bit/4-bit/8-bit CE-ATA devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in Single Data Rate (SDR) mode
- Supports single block, multiblock read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort (both hardware and software CMD12)
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports auto CMD12 for multiblock transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports advanced DMA to perform linked memory access

## 56.2.4 Modes and operations

The SDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit

- MMC 4-bit
- MMC 8-bit
- CE-ATA 1-bit
- CE-ATA 4-bit
- CE-ATA 8-bit
- Identification mode up to 400 kHz
- MMC Full Speed mode up to 20 MHz
- MMC High Speed mode up to 52 MHz
- SD/SDIO Full Speed mode up to 25 MHz
- SD/SDIO High Speed mode up to 50 MHz

## 56.3 SDHC signal descriptions

**Table 56-1. SDHC signal descriptions**

| Signal    | Description   | I/O |
|-----------|---|-----|
| SDHC_DCLK | Generated clock used to drive the MMC, SD, SDIO or CE-ATA cards.  | O   |
| SDHC_CMD  | Send commands to and receive responses from the card.   | I/O |
| SDHC_D0   | DAT0 line or busy-state detect  | I/O |
| SDHC_D1   | 8-bit mode: DAT1 line<br>4-bit mode: DAT1 line or interrupt detect<br>1-bit mode: Interrupt detect                  | I/O |
| SDHC_D2   | 4-/8-bit mode: DAT2 line or read wait<br>1-bit mode: Read wait  | I/O |
| SDHC_D3   | 4-/8-bit mode: DAT3 line or configured as card detection pin<br>1-bit mode: May be configured as card detection pin | I/O |
| SDHC_D4   | DAT4 line in 8-bit mode<br>Not used in other modes  | I/O |
| SDHC_D5   | DAT5 line in 8-bit mode<br>Not used in other modes  | I/O |
| SDHC_D6   | DAT6 line in 8-bit mode<br>Not used in other modes  | I/O |

*Table continues on the next page...*

**Table 56-1. SDHC signal descriptions (continued)**

| Signal  | Description  | I/O |
|---------|--|-----|
| SDHC_D7 | DAT7 line in 8-bit mode<br>Not used in other modes | I/O |

## 56.4 Memory map and register definition

This section includes the module memory map and detailed descriptions of all registers.

### SDHC memory map

| Absolute address (hex) | Register name                                     | Width (in bits) | Access                | Reset value | Section/page                 |
|------------------------|---|-----------------|-----------------------|-------------|------------------------------|
| 400B_1000              | DMA System Address register (SDHC_DSADDR)         | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.1/1895</a>  |
| 400B_1004              | Block Attributes register (SDHC_BLKATTR)          | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.2/1896</a>  |
| 400B_1008              | Command Argument register (SDHC_CMDARG)           | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.3/1897</a>  |
| 400B_100C              | Transfer Type register (SDHC_XFERTYP)             | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.4/1897</a>  |
| 400B_1010              | Command Response 0 (SDHC_CMDRSP0)                 | 32              | R                     | 0000_0000h  | <a href="#">56.4.5/1902</a>  |
| 400B_1014              | Command Response 1 (SDHC_CMDRSP1)                 | 32              | R                     | 0000_0000h  | <a href="#">56.4.6/1902</a>  |
| 400B_1018              | Command Response 2 (SDHC_CMDRSP2)                 | 32              | R                     | 0000_0000h  | <a href="#">56.4.7/1902</a>  |
| 400B_101C              | Command Response 3 (SDHC_CMDRSP3)                 | 32              | R                     | 0000_0000h  | <a href="#">56.4.8/1903</a>  |
| 400B_1020              | Buffer Data Port register (SDHC_DATPORT)          | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.9/1904</a>  |
| 400B_1024              | Present State register (SDHC_PRSTAT)              | 32              | R                     | 0000_0000h  | <a href="#">56.4.10/1904</a> |
| 400B_1028              | Protocol Control register (SDHC_PROCTL)           | 32              | R/W                   | 0000_0020h  | <a href="#">56.4.11/1910</a> |
| 400B_102C              | System Control register (SDHC_SYSCTL)             | 32              | R/W                   | 0000_8008h  | <a href="#">56.4.12/1914</a> |
| 400B_1030              | Interrupt Status register (SDHC_IRQSTAT)          | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.13/1917</a> |
| 400B_1034              | Interrupt Status Enable register (SDHC_IRQSTATEN) | 32              | R/W                   | 117F_013Fh  | <a href="#">56.4.14/1922</a> |
| 400B_1038              | Interrupt Signal Enable register (SDHC_IRQSIGEN)  | 32              | R/W                   | 0000_0000h  | <a href="#">56.4.15/1925</a> |
| 400B_103C              | Auto CMD12 Error Status Register (SDHC_AC12ERR)   | 32              | R                     | 0000_0000h  | <a href="#">56.4.16/1927</a> |
| 400B_1040              | Host Controller Capabilities (SDHC_HTCAPBLT)      | 32              | R                     | 07F3_0000h  | <a href="#">56.4.17/1931</a> |
| 400B_1044              | Watermark Level Register (SDHC_WML)               | 32              | R/W                   | 0010_0010h  | <a href="#">56.4.18/1933</a> |
| 400B_1050              | Force Event register (SDHC_FEVT)                  | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">56.4.19/1934</a> |

Table continues on the next page...

### SDHC memory map (continued)

| Absolute address (hex) | Register name                             | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|---|-----------------|--------|-------------|------------------------------|
| 400B_1054              | ADMA Error Status register (SDHC_ADMAES)  | 32              | R      | 0000_0000h  | <a href="#">56.4.20/1936</a> |
| 400B_1058              | ADMA System Addressregister (SDHC_DSADDR) | 32              | R/W    | 0000_0000h  | <a href="#">56.4.21/1938</a> |

| 400B_10FC              | Host Controller Version (SDHC_HOSTVER)    | 32              | R      | 0000_1201h  | <a href="#">56.4.24/1941</a> |

#### 56.4.1 DMA System Address register (SDHC\_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Address: 400B\_1000h base + 0h offset = 400B\_1000h

#### SDHC\_DSADDR field descriptions

| Field           | Description  |
|-----------------|--|
| 31–2<br>DSADDR  | <p>DMA System Address</p> <p>Contains the 32-bit system memory address for a DMA transfer. Because the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the SDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operation during transfers may return an invalid value. The host driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver shall wait, until PRSSTAT[DLA] is cleared, before writing to this register.</p> <p>The SDHC internal DMA does not support a virtual memory system. It supports only continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, SDHC will automatically change SEQ burst type to NSEQ.</p> <p>Because this register supports dynamic address reflecting, when IRQSTAT[TC] bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when IRQSTAT[TC] is set.</p> |
| 1–0<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>   |

## 56.4.2 Block Attributes register (SDHC\_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: 400B\_1000h base + 4h offset = 400B\_1004h

### SDHC\_BLKATTR field descriptions

| Field             | Description   |
|-------------------|---|
| 31–16<br>BLKCNT   | <p>Blocks Count For Current Transfer</p> <p>This register is enabled when XFERTYP[BCEN] is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The host driver shall set this register to a value between 1 and the maximum block count. The SDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register must be accessed only when no transaction is executing, that is, after transactions are stopped. During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register must be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when suspend command is sent out, SDHC will regard the current transfer as aborted and change BLKCNT back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a resume command, the host driver shall restore the previously saved block count.</p> <p><b>NOTE:</b> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when XFERTYP[MSBSEL] is 0, indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>0000h Stop count.<br/>           0001h 1 block<br/>           0002h 2 blocks<br/>           ...<br/>           FFFFh 65535 blocks</p> |
| 15–13<br>Reserved | <p>This field is reserved.<br/>           This read-only field is reserved and always has the value 0.</p>  |
| 12–0<br>BLKSIZE   | <p>Transfer Block Size</p> <p>Specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operations during transfers may return an invalid value, and write operations will be ignored.</p>   |

Table continues on the next page...

### SDHC\_BLKATTR field descriptions (continued)

| Field | Description       |
|-------|-------------------|
| 000h  | No data transfer. |
| 001h  | 1 Byte            |
| 002h  | 2 Bytes           |
| 003h  | 3 Bytes           |
| 004h  | 4 Bytes           |
| ...   |                   |
| 1FFh  | 511 Bytes         |
| 200h  | 512 Bytes         |
| ...   |                   |
| 800h  | 2048 Bytes        |
| ...   |                   |
| 1000h | 4096 Bytes        |

### 56.4.3 Command Argument register (SDHC\_CMDARG)

This register contains the SD/MMC command argument.

Address: 400B\_1000h base + 8h offset = 400B\_1008h

### SDHC\_CMDARG field descriptions

| Field          | Description  |
|----------------|--|
| 31–0<br>CMDARG | <p>Command Argument</p> <p>The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when PRSSTAT[CDIHB0] is set.</p> |

### 56.4.4 Transfer Type register (SDHC\_XFERTYP)

This register is used to control the operation of data transfers. The host driver shall set this register before issuing a command followed by a data transfer, or before issuing a resume command. To prevent data loss, the SDHC prevents writing to the bits that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver shall check PRSSTAT[CDIHB] and PRSSTAT[CIHB] before writing to this register. When PRSSTAT[CDIHB] is set, any attempt to send a command with data by writing to this register is ignored; when PRSSTAT[CIHB] bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is nonzero. Besides, block count must also be nonzero, or indicated as single block transfer (bit 5 of this register is 0 when written), or block count is disabled (bit 1 of this register is 0 when written), otherwise SDHC will ignore the sending of this command and do nothing.

For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is 1), otherwise SDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, SDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver must issue the command again to retry the transfer. It is also possible that, for some reason, the card responds to the command but SDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The following table shows the summary of how register settings determine the type of data transfer.

**Table 56-7. Transfer Type register setting for various transfer types**

| Multi/Single block select | Block count enable | Block count     | Function          |
|---------------------------|--------------------|-----------------|-------------------|
| 0                         | Don't care         | Don't care      | Single transfer   |
| 1                         | 0                  | Don't care      | Infinite transfer |
| 1                         | 1                  | Positive number | Multiple transfer |
| 1                         | 1                  | Zero            | No data transfer  |

The following table shows the relationship between XFERTYP[CICEN] and XFERTYP[CCCEN], in regards to XFERTYP[RSPTYP] as well as the name of the response type.

**Table 56-8. Relationship between parameters and the name of the response type**

| Response type (RSPTYP) | Index check enable (CICEN) | CRC check enable (CCCEN) | Name of response type |
|------------------------|----------------------------|--------------------------|-----------------------|
| 00                     | 0                          | 0                        | No Response           |
| 01                     | 0                          | 1                        | IR2                   |
| 10                     | 0                          | 0                        | R3,R4                 |
| 10                     | 1                          | 1                        | R1,R5,R6              |
| 11                     | 1                          | 1                        | R1b,R5b               |

**NOTE**

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the SDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: 400B\_1000h base + Ch offset = 400B\_100Ch

**SDHC\_XFERTYP field descriptions**

| Field             | Description   |
|-------------------|---|
| 31–30<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 29–24<br>CMDINX   | Command Index<br><br>These bits shall be set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.  |
| 23–22<br>CMDTYP   | Command Type<br><br>There are three types of special commands: suspend, resume, and abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> <li>• Suspend command: If the suspend command succeeds, the SDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DAT line. Because the SDHC does not monitor the content of command response, it does not know if the suspend command succeeded or not. It is the host driver's responsibility to check the status of the suspend command and send another command marked as suspend to inform the SDHC that a suspend command was successfully issued. After the end bit of command is sent, the SDHC deasserts read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the suspend command fails, the SDHC will maintain its current state, and the host driver shall restart the transfer by setting PROCTL[CREQ].</li> </ul> |

*Table continues on the next page...*

### SDHC\_XFERTYP field descriptions (continued)

| Field           | Description  |
|-----------------|--|
|                 | <ul style="list-style-type: none"> <li>Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the suspend command and then sends the resume command. The SDHC will check for a pending busy state before starting write transfers.</li> <li>Abort command: If this command is set when executing a read transfer, the SDHC will stop reads to the buffer. If this command is set when executing a write transfer, the SDHC will stop driving the DAT line. After issuing the abort command, the host driver must issue a software reset (abort transaction).</li> </ul> <p>00b Normal other commands.<br/>           01b Suspend CMD52 for writing bus suspend in CCCR.<br/>           10b Resume CMD52 for writing function select in CCCR.<br/>           11b Abort CMD12, CMD52 for writing I/O abort in CCCR.</p>        |
| 21<br>DPSEL     | <p>Data Present Select</p> <p>This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following:</p> <ul style="list-style-type: none"> <li>Commands using only the CMD line, for example: CMD52.</li> <li>Commands with no data transfer, but using the busy signal on DAT[0] line, R1b or R5b, for example: CMD38.</li> </ul> <p><b>NOTE:</b> In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, that is, the WPSPL bit is active as 0, any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>0b No data present.<br/>           1b Data present.</p> |
| 20<br>CICEN     | <p>Command Index Check Enable</p> <p>If this bit is set to 1, the SDHC will check the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the index field is not checked.</p> <p>0b Disable<br/>           1b Enable</p>   |
| 19<br>CCEN      | <p>Command CRC Check Enable</p> <p>If this bit is set to 1, the SDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response.</p> <p>0b Disable<br/>           1b Enable</p>   |
| 18<br>Reserved  | <p>This field is reserved.<br/>           This read-only field is reserved and always has the value 0.</p>   |

**SDHC\_XFERTYP field descriptions (continued)**

| Field            | Description   |
|------------------|---|
| 15–6<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 5<br>MSBSEL      | Multi/Single Block Select<br><br>Enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the block count register.<br><br>0b Single block.<br>1b Multiple blocks.  |
| 4<br>DTDSEL      | Data Transfer Direction Select<br><br>Defines the direction of DAT line data transfers. The bit is set to 1 by the host driver to transfer data from the SD card to the SDHC and is set to 0 for all other commands.<br><br>0b Write host to card.<br>1b Read card to host.   |
| 3<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 2<br>AC12EN      | Auto CMD12 Enable<br><br>Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the SDHC will issue a CMD12 automatically when the last block transfer has completed. The host driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the SDHC will ignore this bit whether it is set or not.<br><br>0b Disable<br>1b Enable |
| 1<br>BCEN        | Block Count Enable<br><br>Used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.<br><br>0b Disable<br>1b Enable   |
| 0<br>DMAEN       | DMA Enable<br><br>Enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the host driver sets the DPSEL bit of this register. Whether the simple DMA, or the advanced DMA, is active depends on PROCTL[DMAS].<br><br>0b Disable<br>1b Enable  |

### 56.4.5 Command Response 0 (SDHC\_CMDRSP0)

This register is used to store part 0 of the response bits from the card.

Address: 400B\_1000h base + 10h offset = 400B\_1010h

#### SDHC\_CMDRSP0 field descriptions

| Field           | Description        |
|-----------------|--------------------|
| 31–0<br>CMDRSP0 | Command Response 0 |

### 56.4.6 Command Response 1 (SDHC\_CMDRSP1)

This register is used to store part 1 of the response bits from the card.

Address: 400B\_1000h base + 14h offset = 400B\_1014h

#### SDHC\_CMDRSP1 field descriptions

| Field           | Description        |
|-----------------|--------------------|
| 31–0<br>CMDRSP1 | Command Response 1 |

### 56.4.7 Command Response 2 (SDHC\_CMDRSP2)

This register is used to store part 2 of the response bits from the card.

Address: 400B\_1000h base + 18h offset = 400B\_1018h

### SDHC\_CMDRSP2 field descriptions

| Field           | Description        |
|-----------------|--------------------|
| 31–0<br>CMDRSP2 | Command Response 2 |

### 56.4.8 Command Response 3 (SDHC\_CMDRSP3)

This register is used to store part 3 of the response bits from the card.

The following table describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

**Table 56-13. Response bit definition for each response type**

| Response type             | Meaning of response                               | Response field | Response register                          |
|---------------------------|---|----------------|--|
| R1,R1b (normal response)  | Card status                                       | R[39:8]        | CMDRSP0                                    |
| R1b (Auto CMD12 response) | Card status for auto CMD12                        | R[39:8]        | CMDRSP3                                    |
| R2 (CID, CSD register)    | CID/CSD register [127:8]                          | R[127:8]       | {CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0} |
| R3 (OCR register)         | OCR register for memory                           | R[39:8]        | CMDRSP0                                    |
| R4 (OCR register)         | OCR register for I/O etc.                         | R[39:8]        | CMDRSP0                                    |
| R5, R5b                   | SDIO response                                     | R[39:8]        | CMDRSP0                                    |
| R6 (Publish RCA)          | New published RCA[31:16]<br>and card status[15:0] | R[39:9]        | CMDRSP0                                    |

This table shows that most responses with a length of 48 (R[47:0]) have 32-bit of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bit of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the SDHC stores only a part of the response data in the command response registers. This enables the host driver to efficiently read 32-bit of response data in one read cycle on a 32-bit bus system. Parts of the response, the index field and the CRC, are checked by the SDHC, as specified by XFERTYP[CICEN] and XFERTYP[CCCEN], and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the SDHC will check R[47:1], and if the response length is 136 the SDHC will check R[119:1].

Because the SDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the SDHC stores the auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows the SDHC to avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the SDHC modifies part of the command response registers, as shown in the table above, it preserves the unmodified bits.

Address: 400B\_1000h base + 1Ch offset = 400B\_101Ch

**SDHC\_CMDRSP3 field descriptions**

| Field           | Description        |
|-----------------|--------------------|
| 31-0<br>CMDRSP3 | Command Response 3 |

**56.4.9 Buffer Data Port register (SDHC\_DATPORT)**

This is a 32-bit data port register used to access the internal buffer and it cannot be updated in Idle mode.

Address: 400B\_1000h base + 20h offset = 400B\_1020h

**SDHC\_DATPORT field descriptions**

| Field           | Description  |
|-----------------|--|
| 31-0<br>DATCONT | Data Content<br><br>The Buffer Data Port register is for 32-bit data access by the CPU or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s. |

**56.4.10 Present State register (SDHC\_PRSTAT)**

The host driver can get status of the SDHC from this 32-bit read-only register.

### NOTE

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CIHB) is set to zero. Other commands shall be issued when Command Inhibit (CDIHB) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

Address: 400B\_1000h base + 24h offset = 400B\_1024h

**SDHC\_PRSTAT field descriptions (continued)**

| Field              | Description   |
|--------------------|---|
|                    | <ul style="list-style-type: none"> <li>When the SD card releases write busy of the last data block, the SDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the SDHC shall assume the card drive "Not busy".</li> <li>When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request.</li> </ul> <p><b>In the case of command with busy pending:</b></p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released.</p> <p>0b DAT line inactive.<br/>1b DAT line active.</p>  |
| <p>1<br/>CDIHB</p> | <p>Command Inhibit (DAT)</p> <p>This status bit is generated if either the DLA or the RTA is set to 1. If this bit is 0, it indicates that the SDHC can issue the next SD/MMC Command. Commands with a busy signal belong to CDIHB, for example, R1b, R5b type. Except in the case when the command busy is finished, changing from 1 to 0 generates a transfer complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>0b Can issue command which uses the DAT line.<br/>1b Cannot issue command which uses the DAT line.</p>  |
| <p>0<br/>CIHB</p>  | <p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the SDHC can issue a SD/MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the CDIHB bit is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a command complete interrupt in the interrupt status register. If the SDHC cannot issue the command because of a command conflict error (see command CRC error) or because of a command not issued by auto CMD12 error, this bit will remain 1 and the command complete is not set. The status of issuing an auto CMD12 does not show on this bit.</p> <p>0b Can issue command using only CMD line.<br/>1b Cannot issue command.</p> |

### 56.4.11 Protocol Control register (SDHC\_PROCTL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the SDHC issues a suspend command or the SD card accepts the suspend command:

- If the host driver does not issue a suspend command, the continue request shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card accepts it, a resume command shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card does not accept it, the continue request shall be used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver shall wait for a transfer complete (in the interrupt status register), before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver shall clear the stop at block gap request before or simultaneously.

|-------------------|--|
|                   | 0b Disabled<br>1b Enabled  |
| 25<br>WECINS      | Wakeup Event Enable On SD Card Insertion<br><br>Enables a wakeup event, via IRQSTAT[CINS]. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, IRQSTATEN[CINSEN] and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert IRQSTATEN[CINSEN] and the SDHC interrupt.<br><br>0b Disabled<br>1b Enabled  |
| 24<br>WECINT      | Wakeup Event Enable On Card Interrupt<br><br>Enables a wakeup event, via IRQSTAT[CINT]. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the card interrupt status and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert the card interrupt status and the SDHC interrupt.<br><br>0b Disabled<br>1b Enabled  |
| 23–20<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |
| 19<br>IABG        | Interrupt At Block Gap<br><br>Valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card can't signal an interrupt during a multiple block transfer, this bit must be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.<br><br>0b Disabled<br>1b Enabled   |
| 18<br>RWCTL       | Read Wait Control<br><br>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the SDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the SDHC will stop the SD Clock to pause reading operation.<br><br>0b Disable read wait control, and stop SD clock at block gap when SABGREQ is set.<br>1b Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set. |
| 17<br>CREQ        | Continue Request<br><br>Used to restart a transaction which was stopped using the PROCTL[SABGREQ]. When a suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set PROCTL[SABGREQ] to 0 and set this bit to 1 to restart the transfer.<br><br>The SDHC automatically clears this bit, therefore it is not necessary for the host driver to set this bit to 0. If both PROCTL[SABGREQ] and this bit are 1, the continue request is ignored.   |

### SDHC\_PROCTL field descriptions (continued)

| Field             | Description  |
|-------------------|--|
|                   | 0b No effect.<br>1b Restart  |
| 16<br>SABGREQ     | <p>Stop At Block Gap Request</p> <p>Used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the IRQSTATEN[TCSEN] is set to 1, indicating a transfer completion, the host driver shall leave this bit set to 1. Clearing both PROCTL[SABGREQ] and PROCTL[CREQ] does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The SDHC will honor the PROCTL[SABGREQ] for write transfers, but for read transfers it requires that SDIO card support read wait. Therefore, the host driver shall not set this bit during read transfers unless the SDIO card supports read wait and has set PROCTL[RWCTL] to 1, otherwise the SDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the data port register, the host driver shall set this bit after all block data is written. If this bit is set to 1, the host driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the host driver shall not clear this bit before IRQSTATEN[TCSEN] is set, otherwise the SDHC's behavior is undefined.</p> <p>This bit effects PRSSTAT[RTA], PRSSTAT[WTA], and PRSSTAT[CDIHB].</p> 0b Transfer<br>1b Stop |

### SDHC\_SYSCTL field descriptions

| Field             | Description   |
|-------------------|---|
| 31–28<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 27<br>INITA       | Initialization Active<br><br>When this bit is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this bit is self-cleared. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the PRSSTAT[CIHB] and PRSSTAT[CDIHB] bits are set, writing 1 to this bit is ignored, that is, when command line or data lines are active, write to this bit is not allowed. On the otherhand, when this bit is set, that is, during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self-cleared. |
| 26<br>RSTD        | Software Reset For DAT Line<br>Only part of the data circuit is reset. DMA circuit is also reset.<br>The following registers and bits are cleared by this bit: <ul style="list-style-type: none"> <li>• Data Port register</li> <li>• Buffer Is Cleared And Initialized.Present State register</li> <li>• Buffer Read Enable</li> <li>• Buffer Write Enable</li> <li>• Read Transfer Active</li> </ul>  |

| 19–16<br>DTCV     | <p>Data Timeout Counter Value</p> <p>Determines the interval by which DAT line timeouts are detected. See IRQSTAT[DTOE] for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.</p> <p>The host driver can clear IRQSTATEN[DTOESEN] to prevent inadvertent time-out events.</p> <p>0000b SDCLK x 2<sup>13</sup><br/>0001b SDCLK x 2<sup>14</sup><br/>...<br/>1110b SDCLK x 2<sup>27</sup><br/>1111b Reserved</p>   |
| 15–8<br>SDCLKFS   | <p>SDCLK Frequency Select</p> <p>Used to select the frequency of the SDCLK pin. The frequency is not programmed directly. Rather this register holds the prescaler (this register) and divisor (next register) of the base clock frequency register.</p> <p>Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of SDHC clock and the following divisor bits.</p>   |

*Table continues on the next page...*

### SDHC\_SYSCTL field descriptions (continued)

| Field        | Description  |
|--------------|--|
|              | <p>The frequency of SDCLK is set by the following formula: Clock frequency = (Base clock) / (prescaler x divisor)</p> <p>For example, if the base clock frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input base clock ( SDHC clock ) is about 96 MHz, the default SD clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and shall never exceed this limit.</p> <p>Only the following settings are allowed:</p> <p>01h Base clock divided by 2.<br/>           02h Base clock divided by 4.<br/>           04h Base clock divided by 8.<br/>           08h Base clock divided by 16.<br/>           10h Base clock divided by 32.<br/>           20h Base clock divided by 64.<br/>           40h Base clock divided by 128.<br/>           80h Base clock divided by 256.</p> |
| 7-4<br>DVS   | <p>Divisor</p> <p>Used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisor without deterioration of duty cycle.</p> <p>The setting are as following:</p> <p>0h Divisor by 1.<br/>           1h Divisor by 2.<br/>           ...<br/>           Eh Divisor by 15.<br/>           Fh Divisor by 16.</p>  |
| 3<br>SDCLKEN | <p>SD Clock Enable</p> <p>The host controller shall stop SDCLK when writing this bit to 0. SDCLK frequency can be changed when this bit is 0. Then, the host controller shall maintain the same clock frequency until SDCLK is stopped (stop at SDCLK = 0). If the IRQSTAT[CINS] is cleared, this bit must be cleared by the host driver to save power.</p>  |
| 2<br>PEREN   | <p>Peripheral Clock Enable</p> <p>If this bit is set, SDHC clock will always be active and no automatic gating is applied. Thus the SDCLK is active except for when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the SDHC clock will be automatically off whenever there is no transaction on the SD bus. Because this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The SDHC clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>• The cmd part is reset, or</li> <li>• Data part is reset, or</li> <li>• A soft reset, or</li> <li>• The cmd is about to send, or</li> <li>• Clock divisor is just updated, or</li> <li>• Continue request is just set, or</li> <li>• This bit is set, or</li> <li>• Card insertion is detected, or</li> <li>• Card removal is detected, or</li> </ul>  |

Table continues on the next page...

| Field      | Description   |
|------------|---|
|            | <ul style="list-style-type: none"> <li>• Card external interrupt is detected, or</li> <li>• 80 clocks for initialization phase is ongoing</li> </ul> 0b SDHC clock will be internally gated off.<br>1b SDHC clock will not be automatically gated off.  |
| 1<br>HCKEN | <p>System Clock Enable</p> <p>If this bit is set, system clock will always be active and no automatic gating is applied. When this bit is cleared, system clock will be automatically off when no data transfer is on the SD bus.</p> 0b System clock will be internally gated off.<br>1b System clock will not be automatically gated off.   |
| 0<br>IPGEN | <p>IPG Clock Enable</p> <p>If this bit is set, bus clock will always be active and no automatic gating is applied. The bus clock will be internally gated off, if none of the following factors are met:</p> <ul style="list-style-type: none"> <li>• The cmd part is reset, or</li> <li>• Data part is reset, or</li> <li>• Soft reset, or</li> <li>• The cmd is about to send, or</li> <li>• Clock divisor is just updated, or</li> <li>• Continue request is just set, or</li> <li>• This bit is set, or</li> <li>• Card insertion is detected, or</li> <li>• Card removal is detected, or</li> <li>• Card external interrupt is detected, or</li> <li>• The SDHC clock is not gated off</li> </ul> <p><b>NOTE:</b> The bus clock will not be auto gated off if the SDHC clock is not gated off. So clearing only this bit has no effect unless the PEREN bit is also cleared.</p> 0b Bus clock will be internally gated off.<br>1b Bus clock will not be automatically gated off. |

**56.4.13 Interrupt Status register (SDHC\_IRQSTAT)**

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the CTOE and the CC bits.

**Table 56-19. SDHC status for CTOE/CC bit combinations**

| Command complete | Command timeout error | Meaning of the status                        |
|------------------|-----------------------|--|
| 0                | 0                     | X  |
| X                | 1                     | Response not received within 64 SDCLK cycles |
| 1                | 0                     | Response received                            |

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 56-20. SDHC status for data timeout error/transfer complete bit combinations**

| Transfer complete | Data timeout error | Meaning of the status            |
|-------------------|--------------------|----------------------------------|
| 0                 | 0                  | X                                |
| 0                 | 1                  | Timeout occurred during transfer |
| 1                 | X                  | Data transfer complete           |

The table below shows the relationship between the command CRC Error (CCE) and Command Timeout Error (CTOE).

**Table 56-21. SDHC status for CCE/CTOE Bit Combinations**

| Command complete | Command timeout error | Meaning of the status  |
|------------------|-----------------------|------------------------|
| 0                | 0                     | No error               |
| 0                | 1                     | Response timeout error |
| 1                | 0                     | Response CRC error     |
| 1                | 1                     | CMD line conflict      |

| 8<br>CINT        | <p>Card Interrupt</p> <p>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the SDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this bit to 1 can clear this bit, but as the interrupt factor from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt factor from the external card followed by a writing 1 to this bit.</p> |

Table continues on the next page...

**SDHC\_IRQSTAT field descriptions (continued)**

| Field     | Description  |
|-----------|--|
|           | <p>When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (it must reset the interrupt factors in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.</p> <p>0b No Card Interrupt.<br/>1b Generate Card Interrupt.</p>   |
| 7<br>CRM  | <p>Card Removal</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. To leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.</p> <p>0b Card state unstable or inserted.<br/>1b Card removed.</p>   |
| 6<br>CINS | <p>Card Insertion</p> <p>This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. #### 56.4.14 Interrupt Status Enable register (SDHC\_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding interrupt status to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is also cleared, that is, when the bit in this register is cleared, the corresponding bit in interrupt status register is always 0.

**NOTE**

- Depending on PROCTL[IABG] bit setting, SDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the card interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both IRQSTATEN[CTOESEN] and IRQSTATEN[CCESSEN] to 1.

**56.4.15 Interrupt Signal Enable register (SDHC\_IRQSIGEN)**

This register is used to select which interrupt status is indicated to the host system as the interrupt. All of these status bits share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Address: 400B\_1000h base + 38h offset = 400B\_1038h

**56.4.16 Auto CMD12 Error Status Register (SDHC\_AC12ERR)**

When the AC12ESEN bit in the Status register is set, the host driver shall check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The following table shows the relationship between the Auto CMGD12 CRC error and the Auto CMD12 command timeout error.

**Table 56-25. Relationship between Command CRC Error and Command Timeout Error For Auto CMD12**

| Auto CMD12 CRC error | Auto CMD12 timeout error | Type of error          |
|----------------------|--------------------------|------------------------|
| 0                    | 0                        | No error               |
| 0                    | 1                        | Response timeout error |
| 1                    | 0                        | Response CRC error     |
| 1                    | 1                        | CMD line conflict      |

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the SDHC is going to issue an Auto CMD12:
  - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command.
  - Set bit 0 to 0 if the auto CMD12 is issued.
2. At the end bit of an auto CMD12 response:
  - Check errors corresponding to bits 1-4.
  - Set bits 1-4 corresponding to detected errors.
  - Clear bits 1-4 corresponding to detected errors.
3. Before reading the Auto CMD12 error status bit 7:
  - Set bit 7 to 1 if there is a command that can't be issued.
  - Clear bit 7 if there is no command to issue.

The timing for generating the auto CMD12 error and writing to the command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the command register. So it is suggested to read this register only when `IRQSTAT[AC12E]` is set. An Auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

Address: 400B\_1000h base + 3Ch offset = 400B\_103Ch

**SDHC\_AC12ERR field descriptions**

| Field            | Description   |

### 56.4.19 Force Event register (SDHC\_FEVT)

The Force Event (FEVT) register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding bit of the Interrupt Status Enable register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status register. A read from this register always results in 0's. To change the corresponding status bits in the interrupt status register, make sure to set SYSCTL[IPGEN] so that bus clock is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is selfcleared.

Address: 400B\_1000h base + 50h offset = 400B\_1050h

**56.4.20 ADMA Error Status register (SDHC\_ADMAES)**

When an ADMA error interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- **ST\_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST\_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST\_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST\_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver must use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data may exist in the host controller.

The host controller generates the ADMA error interrupt when it detects invalid descriptor data (valid = 0) in the ST\_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

**Table 56-30. ADMA Error State coding**

| D01-D00 | ADMA Error State when error has occurred | Contents of ADMA System Address register                    |
|---------|--|---|
| 00      | ST_STOP (Stop DMA)                       | Holds the address of the next executable descriptor command |
| 01      | ST_FDS (fetch descriptor)                | Holds the valid descriptor address                          |
| 10      | ST_CADR (change address)                 | No ADMA error is generated                                  |
| 11      | ST_TFR (Transfer Data)                   | Holds the address of the next executable descriptor command |

Address: 400B\_1000h base + 54h offset = 400B\_1054h

## 56.5 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA crossbar switch interface, dual-port memory wrapper, data/command controller, clock & reset manager, and clock generator.

### 56.5.1 Data buffer

The SDHC uses one configurable data buffer, so that data can be transferred between the system bus and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). The following diagram illustrates the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

**Figure 56-27. SDHC buffer scheme**

There are 3 transfer modes to access the data buffer:

- CPU Polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RDWML watermark value, then by polling IRQSTAT[BRR] the host driver can read the DATPORT register to fetch the amount of words set in the WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RDWML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately deasserted when there is an access on the DATPORT register. If the number of words in the buffer after the current burst meets or exceeds RDWML value, then the DMA request is asserted again. For instance if there are twice as many words in the buffer than the RDWML value, there are two successive DMA requests with only one cycle of deassertion between. The write operation is similar.

Note the accesses CPU Polling mode and External DMA mode both use the IP bus, and if the external DMA is enable, in both modes an external DMA request is sent out whenever the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA access's):
  - The internal DMA access, either by simple or advanced DMA, is over the crossbar switch bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in WML, the internal DMA starts fetching data over the crossbar switch bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of WML
2. Watermark level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor if the ADMA is active
5. 1 KB address boundary

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software, as illustrated in the following diagrams. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

**Figure 56-28. Data swap between system bus and SDHC data buffer in byte little endian mode**

**Figure 56-29. Data swap between system bus and SDHC data buffer in half word big endian mode**

### 56.5.1.1 Write operation sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. Using external DMA through the SDHC DMA request signal.
2. Processor core polling through IRQSTAT[BWR] (interrupt or polling).
3. Using the internal DMA.

When the internal DMA is not used, that is, the XFERTYP[DMAEN] bit is not set when the command is sent, the SDHC asserts a DMA request when the amount of buffer space exceeds the value set in WML, and is ready for receiving new data. At the same time, the SDHC would set IRQSTAT[BWR]. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the contents of the DSADDR to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the write operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The SDHC will not start data transmission until the number of words set in WML can be held in the buffer. If the buffer is empty and the host system does not write data in time, the SDHC will stop the SD\_CLK to avoid the data buffer underrun situation.

### 56.5.1.2 Read operation sequence

There are three ways to read data from the buffer when the user transfers data to the card:

1. Using the external DMA through the SDHC DMA request signal
2. Processor core polling through IRQSTAT[BRR] (interrupt or polling)
3. Using the internal DMA

When internal DMA is not used, that is, XFERTYP[DMAEN] is not set when the command is sent, the SDHC asserts a DMA request when the amount of data exceeds the value set in WML, that is available and ready for system fetching data. At the same time, the SDHC would set IRQSTAT[BRR]. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the content of the DMA system address register to get the

starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

For any write transfer mode, the SDHC will not start data transmission until the number of words set in WML are in the buffer. If the buffer is full and the Host System does not read data in time, the SDHC will stop the SDHC\_DCLK to avoid the data buffer overrun situation.

### 56.5.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to use it in the most optimized way. In the SDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length can be from 1 word to the maximum of 31 words. The host driver may configure the value according to the system situation and requirement.

During a multiblock data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive, which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it doesn't support a partial block access, which is not the integer times of 512 bytes.

For block size not times of 4, that is, not word aligned, SDHC requires stuff bytes at the end of each block, because the SDHC treats each block individually. For example, the block size is 7 bytes, there are 12 blocks to write, the system side must write 2 times for each block, and for each block, the ending byte would be abandoned by the SDHC because it sends only 7 bytes to the card and picks data from the following system write, so there would be 24 beats of write access in total.

### 56.5.1.4 Dividing large data transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

The following diagram illustrates the dividing of large data transfers. Assuming a kind of WLAN SDIO card supports block size only up to 64 bytes. Although the SDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided. See the example below.

**Figure 56-30. Example for dividing large data transfers**

### 56.5.1.5 External DMA request

When the internal DMA is not in use, and external DMA request is enabled, the data buffer will generate a DMA request to the system. During a write operation, when the number of WRWML words can be held in the buffer free space, a DMA request is sent, informing the host system of a DMA write. IRQSTAT[BWR] is also set, as long as

IRQSTATEN[BWRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RDWML words are already in the buffer, a DMA request is sent, informing the host system for a DMA read. IRQSTAT[BRR] is also set, as long as IRQSTATEN[BRRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer underrun for read operation or overrun for write operation. For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of 2 between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size but not greater than 128 words. This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The SDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level must be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKATTR[BLKSIZE] bits shall be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the SDHC will also set the IRQSTAT[BWR] or IRQSTAT[BRR] bits when the remaining data does not violate data buffer. See [DMA burst length](#) for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred via the DATPORT register, the SDHC will transfer only 31 bytes over the SD bus, as required by the BLKATTR[BLKSIZE] bits. In this data transfer, with non-word aligned block size, the endian mode must be set cautiously, or invalid data will be transferred to/from the card.

## 56.5.2 DMA crossbar switch interface

The internal DMA implements a DMA engine and the crossbar switch master. When the internal DMA is enabled (XFERTYP[DMAEN] is set), the interrupt status bits are set if they are enabled. To avoid setting them, clear IRQSTATEN[BWRSEN, BRRSEN]. The following diagram illustrates the DMA crossbar switch interface block.

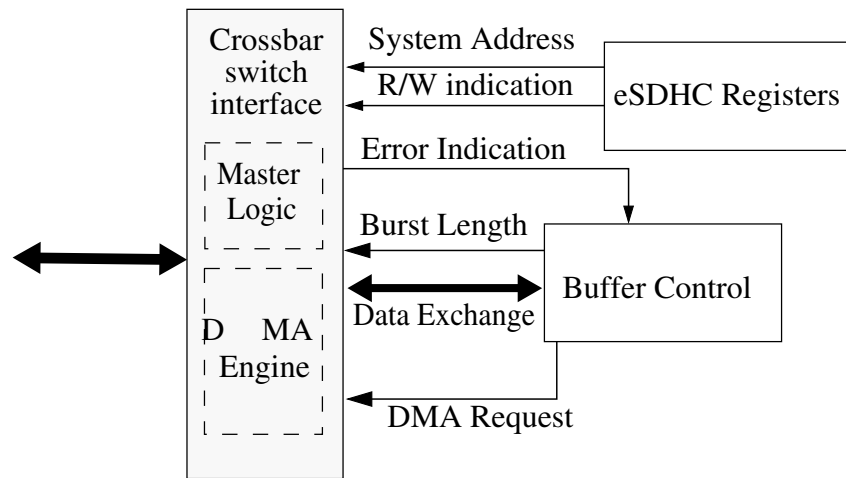

Figure 56-31. DMA crossbar switch interface block

### 56.5.2.1 Internal DMA request

If the watermark level requirement is met in data transfer, and the internal DMA is enabled, the data buffer block sends a DMA request to the crossbar switch interface. Meanwhile, the external DMA request signal is disabled. The delay in response from the internal DMA engine depends on the system bus loading and the priority assigned to the SDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multiblock data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer, which might contain some data of the next block, another DMA request read is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The SDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

### 56.5.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in [Internal DMA request](#) again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block

starts, which is 31 bytes, more than 6 words. The host driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

### 56.5.2.3 Crossbar switch master interface

It is possible that the internal DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. IRQSTAT[DMAE] is set to inform the driver.

After the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read DSADDR[DSADDR] to get the starting address of the corrupted block. After the DMA error is fixed, the software must apply a data reset and restart the transfer from this address to recover the corrupted block.

### 56.5.2.4 ADMA engine

In the SDHC standard, the new DMA transfer algorithm called the advanced DMA (ADMA) is defined. For simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention would not be needed during long DMA-based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in host controller. ADMA1 can support data transfer of 4 KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of descriptor table are different.

ADMA can recognize all kinds of descriptors defined in the SDHC standard, and if end flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### 56.5.2.4.1 ADMA concept and descriptor format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor

- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the Valid flag of descriptor is 0, it will ignore the high 32-bit. The address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before tran type descriptor. Every tran type will trigger a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous trans descriptor, the data length will be the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, tran type descriptor contains both the data length and transfer data address, so only a tran type descriptor can start a data transfer.

**Table 56-35. Format of the ADMA1 descriptor table**

| Address/page field     |      | Address/page field |                 | Attribute field |      |             |     |     |       |
|------------------------|------|--------------------|-----------------|-----------------|------|-------------|-----|-----|-------|
| 31                     | 12   | 11                 | 6               | 5               | 4    | 3           | 2   | 1   | 0     |
| Address or data length |      | 000000             |                 | Act2            | Act1 | 0           | Int | End | Valid |
| Act2                   | Act1 | Symbol             | Comment         | 31-28           |      | 27-12       |     |     |       |
| 0                      | 0    | nop                | No operation    | Don't care      |      |             |     |     |       |
| 0                      | 1    | set                | Set data length | 0000            |      | Data length |     |     |       |
| 1                      | 0    | tran               | Transfer data   | Data address    |      |             |     |     |       |

*Table continues on the next page...*

**Table 56-35. Format of the ADMA1 descriptor table (continued)**

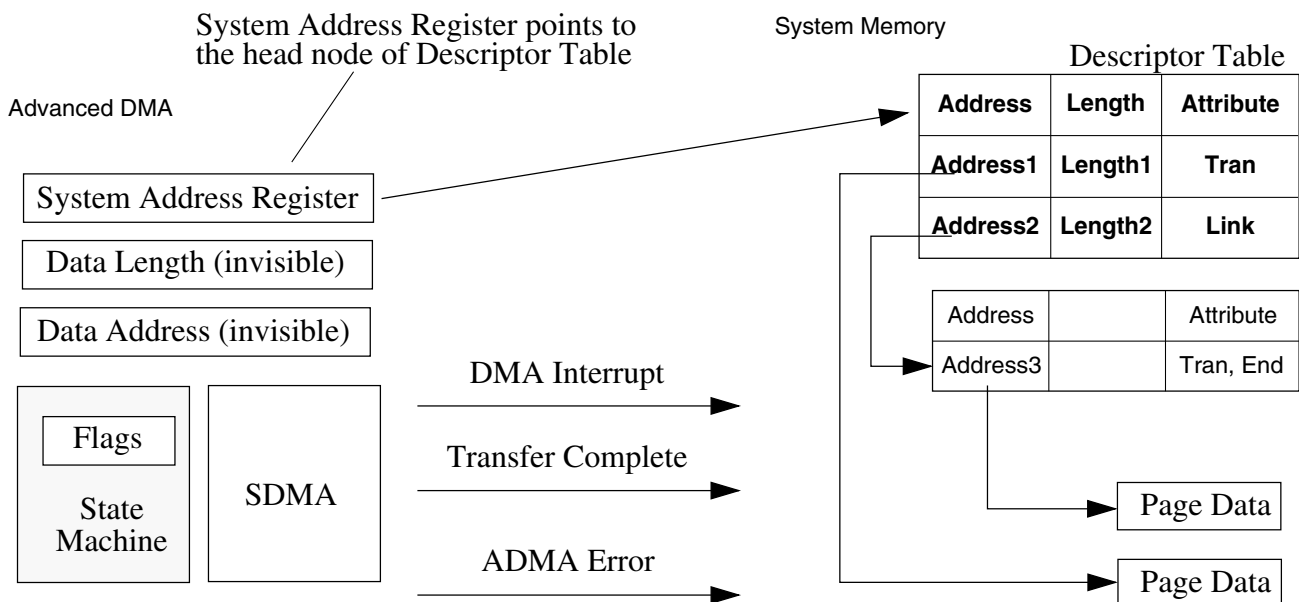

|       |   |      |                 |                    |
|-------|---|------|-----------------|--------------------|
| 1     | 1   | link | Link descriptor | Descriptor address |
| Valid | Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA error Interrupt and stop ADMA. |      |                 |                    |
| End   | End = 1 indicates current descriptor is the ending one.   |      |                 |                    |
| Int   | Int = 1 generates DMA interrupt when this descriptor is processed.  |      |                 |                    |

**Figure 56-32. Concept and access method of ADMA1 descriptor table**

**Table 56-36. Format of the ADMA2 descriptor table**

| Address field  |      | Length  |                 | Reserved  |    | Attribute field |      |    |     |     |       |
|----------------|------|---|-----------------|---|----|-----------------|------|----|-----|-----|-------|
| 63             | 32   | 31  | 16              | 15  | 06 | 05              | 04   | 03 | 02  | 01  | 00    |
| 32-bit address |      | 16-bit length   |                 | 0000000000  |    | Act2            | Act1 | 0  | Int | End | Valid |
| Act2           | Act1 | Symbol  | Comment         | Operation   |    |                 |      |    |     |     |       |
| 0              | 0    | nop   | No operation    | Don't care  |    |                 |      |    |     |     |       |
| 0              | 1    | rsv   | Reserved        | Same as nop. Read this line and go to next one                    |    |                 |      |    |     |     |       |

| 1              | 1    | link  | Link descriptor | Link to another descriptor  |    |                 |      |    |     |     |       |
| Valid          |      | Valid = 1 indicates this line of descriptor is effective. If valid = 0 generate ADMA error interrupt and stop ADMA. |                 |   |    |                 |      |    |     |     |       |
| End            |      | End = 1 indicates current descriptor is the ending one.   |                 |   |    |                 |      |    |     |     |       |
| Int            |      | Int = 1 generates DMA interrupt when this descriptor is done.   |                 |   |    |                 |      |    |     |     |       |

**Figure 56-33. Concept and access method of ADMA2 descriptor table**

### 56.5.2.4.2 ADMA interrupt

If the interrupt flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

### 56.5.2.4.3 ADMA error

The ADMA stops whenever any error is encountered. These errors include:

- Fetching descriptor error

**functional description**

- Transfer error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect the valid flag in the descriptor. If ADMA descriptor error occurs, the interrupt is not generated even if the interrupt flag of this descriptor is set.

When XFERTYP[BCEN] is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If XFERTYP[BCEN] is not set, the whole data length set in descriptor must be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

### 56.5.3 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into the corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

### 56.5.3.1 SD transceiver

In the SD protocol unit, the transceiver is the main control module. It consists of a FSM and control module, from which the control signals for all other three modules are generated.

### 56.5.3.2 SD clock & monitor

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the register bank. The driver can use this for debug purposes.

The module also detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when PROCTL[D3CD] is set.

The module detects the write protect (WP) line. With the information of the WP state, the register bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this module will open and the SD clock will be active again.

This module also drives the SDHC\_LCTL output signal when PROCTL[LCTL] is set by the driver.

### 56.5.3.3 Command agent

The command agent deals with the transactions on the CMD line. The following diagram illustrates the structure for the command CRC Shift Register.

## functional description

**Figure 56-34. Command CRC Shift Register**

The CRC polynomials for the CMD line are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

### 56.5.3.4 Data agent

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DAT[0] line, and generates the read wait state by the request from the transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

### 56.5.4 Clock and reset manager

This module controls all the reset signals within the SDHC.

There are four kinds of reset signals within the SDHC:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

There are three clocks inside the SDHC:

- Bus clock
- SDHC clock
- System clock

The module monitors the activities of all other modules, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

### 56.5.5 Clock generator

The clock generator generates the SDHC\_CLK by peripheral source clock in two stages. The following diagram illustrates the structure of the divider. The term "base" represents the frequency of peripheral source clock.

**Figure 56-35. Two stages of the clock divider**

The first stage outputs an intermediate clock (DIV), which can be base, base/2, base/3, ..., or base/16.

The second stage is a prescaler, and outputs the actual clock (SDHC\_CLK). This clock is the driving clock for all submodules of the SD protocol unit, and the sync FIFOs to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4, ..., or DIV/256. Thus, the highest frequency of the SDHC\_CLK is base, and the next highest is base/2, while the lowest frequency is base/4096. If the base clock is of equal duty ratio (usually true), the duty cycle of SDHC\_CLK is also 50%, even when the compound divisor is an odd value.

### 56.5.6 SDIO card interrupt

This section discusses SDIO interrupt handling.

#### 56.5.6.1 Interrupts in 1-bit mode

In this case, the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

### 56.5.6.2 Interrupt in 4-bit mode

Because the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will be sent by the card and recognized by the host only during a specific time. This is known as the interrupt period. The SDHC will only sample the level on pin 8 during the interrupt period. At all other times, the host will ignore the level on pin 8, and treat it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the interrupt period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the interrupt period. In this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the SDHC\_D1 line will be held low for one clock cycle with the last clock cycle pulling SDHC\_D1 high. On completion of the Interrupt Period, the card releases the SDHC\_D1 line into the high Z state. The SDHC samples the SDHC\_D1] during the interrupt period when PROCTL[IABG] is set.

See the SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 56.5.6.3 Card interrupt handling

When IRQSIGEN[CINTIEN] is set to 0, the SDHC clears the interrupt request to the host system. The host driver must clear this bit before servicing the SDIO Interrupt and must set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the SDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the host system interrupt controller. When the SDIO status has been set, and the host driver needs to service this interrupt, so the SDIO bit in the interrupt control register of the SDIO card will be cleared. This is required to clear the

SDIO interrupt status latched in the SDHC and to stop driving the interrupt signal to the system interrupt controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the SDHC starts sampling the interrupt signal again.

The following diagram illustrates the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 56-36. Card interrupt scheme and card interrupt detection and handling procedure**

### 56.5.7 Card insertion and removal detection

The SDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the SDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card

detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the SDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

## 56.5.8 Power management and wakeup events

When there is no operation between the SDHC and the card through the SD bus, the user can completely disable the bus clock and the SDHC clock in the chip-level clock control module to save power. When the user needs to use the SDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the SDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The SDHC can generate these interrupt even when there are no clocks enabled.

The three interrupts which can be used as wakeup events are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The SDHC offers a power management feature. By clearing the clock enabled bits in the system control register, the clocks are gated in the low position to the SDHC. For maximum power saving, the user can disable all the clocks to the SDHC when there is no operation in progress.

These three wakeup events, or wakeup interrupts, can also be used to wake up the system from low-power modes.

### Note

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low-power mode, the corresponding wakeup enabled bit needs to be set. See Protocol Control register for more information.

### 56.5.8.1 Setting wakeup events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters Sleep mode. Before the software disables the host clock, it must ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

### 56.5.9 MMC fast boot

In Embedded MultiMediaCard(eMMC4.3) spec, add fast boot feature needs hardware support.

In Boot Operation mode, the master (multimediacard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of Fast Boot mode, boot operation, and Alternative boot operation in eMMC4.3 spec. Each type also has with acknowledge and without acknowledge modes.

#### Note

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

#### 56.5.9.1 Boot operation

#### Note

In this block guide, this fast boot is called Normal Fast Boot mode.

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that Boot mode is being initiated and starts preparing boot data internally.

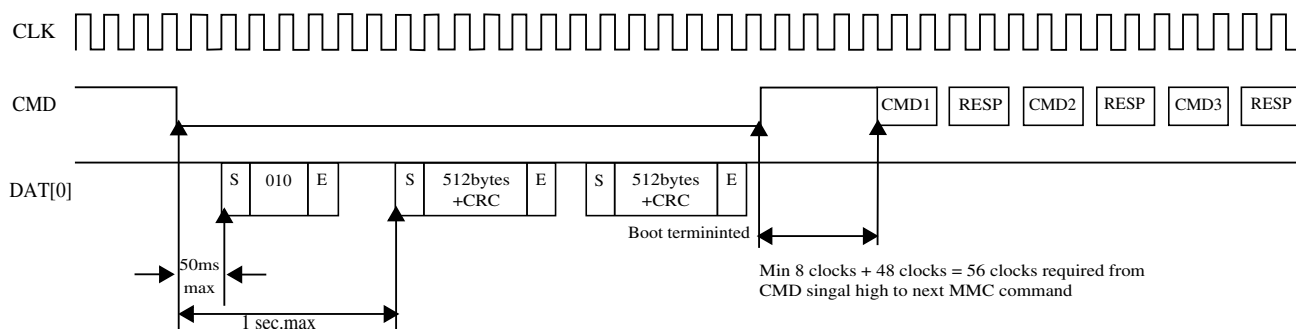

Within 1 second after the CMD line goes low, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line low to read all of the boot data.

## functional description

If boot acknowledge is enabled, the slave has to send acknowledge pattern 010 to the master within 50 ms after the CMD line goes low. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate Boot mode with the CMD line high.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 56-37. Multimediacard state diagram in Normal Boot mode**

### 56.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to 1, the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued, or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 56-38. MultiMediaCard state diagram in Alternative Boot mode**

## 56.6 Initialization/application of SDHC

All communication between system and cards are controlled by the host. The host sends commands of two types:

- Broadcast
- Addressed point-to-point

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID, and so on. In Broadcast mode, all cards are in the Open-Drain mode to avoid bus contention. See [Commands for MMC/SD/SDIO/CE-ATA](#) for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter Standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to Push-Pull mode, to have the driving capability for maximum frequency operation. See [Commands for MMC/SD/SDIO/CE-ATA](#) for the commands of ac and adtc categories.

### 56.6.1 Command send and response receive basic operation

Assuming the data type WORD is an unsigned 32-bit integer, the following flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
```

**Initialization/application of SDHC**

```

if (multi-block transfer) {
    set MSBSEL bit;
    if (finite block number) {
        set BCEN bit;
        if (auto12 command is to use) set AC12EN bit;
    }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}

```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the command complete interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

In some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the standby state, no response to the host when CMD2 is sent. The host driver shall deal with 'fake' errors like this with caution.

## 56.6.2 Card Identification mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the relative card address (RCA) or to set the RCA for the MMC cards. For CE-ATA, the device is connected in a point-to-point manner, and no RCA is needed. All data communications in the Card Identification mode use the command line (CMD) only. See CE-ATA Digital Protocol, Revision 1.1 for more details.

### 56.6.2.1 Card detect

The following diagram illustrates the detection of MMC, SD, and SDIO cards using the SDHC.

**Figure 56-39. Flow diagram for card detection**

Here is the card detection sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the SDHC is received, check IRQSTAT[CINS] in the Interrupt Status register to see whether it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

To detect a CE-ATA device, after completing the normal MMC reset and initialization procedures, the host driver shall issue CMD 60 to check for a CE-ATA signature. If the device responds to the command with the CE-ATA signature, a CE-ATA device has been found. Then the driver must query EXT\_CSD register byte 504 (S\_CMD\_SET) in the MMC register space. If the ATA bit (bit 4) is set, then the MMC device is an ATA device. If the device indicates that it is an ATA device, the Driver must set the ATA bit (bit 4) of the EXT\_CSD register byte 191 (CMD\_SET) to activate the ATA command set for use. To choose the command set, the driver shall issue CMD6. It is possible that the CE-ATA device does not support the ATA mode, so the driver shall not issue ATA command to the device.

### 56.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (card and host) which is driven by power on reset (POR)

- Software reset (host only) is initiated by the write operation of the SYSCTL[RSTD], SYSCTL[RSTC], or SYSCTL[RSTA] bits to reset the data part, command part, or all parts of the host controller, respectively
- Card reset (card only). The command, Go\_Idle\_State (CMD0), is the software reset command for all types of MMC cards, SD Memory cards, and CE-ATA cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA = 0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. The following diagram illustrates the software flow to reset both the SDHC and the card.

For CE-ATA device that supports ATA mode, before issuing CMD0 to reset the MMC layer, two CMD39 should be issued back-to-back to the ATA control register. The first CMD39 shall have the SRST bit set to 1. The second CMD39 command shall have the SRST bit cleared to 0.

**Figure 56-40. Flow chart for reset of the SDHC and SD I/O card**

```

software_reset ()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

### 56.6.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for  $V_{DD}$  are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are able to communicate this information only under data transfer  $V_{DD}$  conditions. This means if the host and card have noncommon  $V_{DD}$  ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. For a CE-ATA card, the process is the same as that of an MMC card. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the  $V_{DD}$  range(s) desired by the host. This is accomplished by the host sending the desired  $V_{DD}$  voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the inactive state. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a nonusable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
  if (0 < number of IO functions) {
    label the card as SDIO;
    IORDY = 0;
    while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
      send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
      wait_for_response(IO_SEND_OP_COND);
    } // end of while ...
  } // end of if (0 < ...
  if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an
  SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
  send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
for memory part or SD card
  wait_for_response(SD_APP_OP_COND); // voltage range is set
  if (card type is UNKNOWN) label the card as SD;
}
}

```

```

return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card or CE-ATA card
if (card is already labelled as SDCombo) { // change label
re-label the card as SDIO;
ignore the error or report it;
return; // card is identified as SDIO card
} // of if (card is ...
send_command(SEND_OP_COND, <voltage range>, <...>);
if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
label the card as UNKNOWN;
return;
} // of if (RESP_TIMEOUT ...
if (check for CE-ATA signature succeeded) { // the card is CE-ATA
store CE-ATA specific info from the signature;
label the card as CE-ATA;
} // of if (check for CE-ATA ...
else label the card as MMC;
} // of else
}

```

### 56.6.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different. For CE-ATA, it enters the tran state after reset is completed.

For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V, as defined by the card specification. At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the inactive state. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified, in the ready state, send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in Open-Drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated, the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the wired OR operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state.

The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards, the cards in ready state, simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Because the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the Identification state.

Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). When the RCA is received the card state changes to the standby state, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For CE-ATA operation (same interface as MMC cards):

```
card_registry()
{
do { // decide RCA for each card until response time-out
  if(card is labelled as SDCCombo or SDIO) { // for SDIO card like device
    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
    retrieve RCA from response;
  } // end if (card is labelled as SDCCombo ...
  else if (card is labelled as SD) { // for SD card
    send_command(ALL_SEND_CID, <...>);
    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
    send_command(SET_RELATIVE_ADDR, <...>);
    retrieve RCA from response;
  } // else if (card is labelled as SD ...
  else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
    send_command(ALL_SEND_CID, <...>);
    rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
  } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

### 56.6.3 Card access

This section discusses the various card access methods.

#### 56.6.3.1 Block write

This section discusses the block write access methods.

##### 56.6.3.1.1 Normal write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the dat line. The transferred data will be discarded and not written, and all further transmitted blocks in Multiple Block Write mode will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set, and the CE-ATA card does not support partial block write, either), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-Data-state for a stop command. For a CE-ATA card, check the CE-ATA card specification for its behavior in block misalignment. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO and CE-ATA cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 to select a different card to place the card into the Standby state and release the DAT line without interrupting the

write operation. When reselecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods, by means of external DMA or CPU polling status, with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
  - c. For CE-ATA cards, configure bits 1~0 in the scrControl register
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the eSDHC DMA when sending the command with data transfer. AC12EN should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 56.6.3.1.2 Write with pause

The write operation can be paused during the transfer. Instead of stopping the SD\_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set PROCTL[SABGREQ] to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to deassert to release the busy state, no suspend command is needed.

Like the flow described in [Normal write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
  - c. For CE-ATA cards, configure bits 1~0 in the scrControl register
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the SDHC DMA when sending the command with data transfer. The XFERTYP[AC12EN] bit should also be set.
6. Set PROCTL[SABGREQ].
7. Wait for the transfer complete interrupt.
8. Clear PROCTL[SABGREQ].
9. Check the status bit to see whether a write CRC error occurred.
10. Set PROCTL[CREQ] to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKATTR[BLKCNT] . As the data transfer and the setting of the PROCTL[SABGREQ] bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The driver shall read the value of BLKATTR[BLKCNT] after the transfer is paused and the transfer complete interrupt is received.

It is also possible that the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the suspend command for the SDIO card. This is because when such a command is sent, the SDHC thinks the system will switch to another function on the SDIO card, and flush the data buffer. The SDHC takes the resume command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set as well as XFERTYP[AC12EN]. However, the SDHC will automatically send a CMD12 to mark the end of the multiblock transfer.

### 56.6.3.2 Block read

This section discusses the block read access methods.

#### 56.6.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)

- b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
  - c. For CE-ATA cards, configure bits 1~0 in the scrControl register
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the SDHC DMA when sending the command with data transfer. XFERTYP[AC12EN] must also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

### 56.6.3.2.2 Read with pause

The read operation is not generally able to pause. Only the SDIO card and SDCombo card working under I/O mode supporting the read and wait feature can pause during the read operation. If the SDIO card support read wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the eSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. Set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Like the flow described in [Normal read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set RWCTL.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
  - a. For SD/MMC, use SET\_BLOCKLEN (CMD16)

- b. For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
  - c. For CE-ATA cards, configure bits 1~0 in the scrControl register
5. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
  6. Set the SDHC number block register (NOB), nob is 5 (for instance).
  7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. AC12EN must also be set.
  8. Set SABGREQ.
  9. Wait for the Transfer Complete interrupt.
  10. Clear SABGREQ.
  11. Check the status bit to see whether read CRC error occurred.
  12. Set CREQ to continue the read operation.
  13. Wait for the Transfer Complete interrupt.
  14. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the SDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. Whether the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the SDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the SDHC will automatically send the CMD12 to mark the end of multi-block transfer.

### 56.6.3.3 Suspend resume

The SDHC supports the suspend resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

#### 56.6.3.3.1 Suspend

After setting the PROCTL[SABGREQ] bit, the host driver may send a suspend command to switch to another function of the SDIO card. The SDHC does not monitor the content of the response, therefore it doesn't know whether the suspend command succeeded or not. Accordingly, it doesn't deassert read wait for read pause. To solve this problem, the driver shall not mark the suspend command as a suspend, that is, setting the XFERTYP[CMDTYP] bits to 01. Instead, the driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the driver send another command marked as suspend to inform the SDHC that the current transfer is suspended. As shown in the following sequence for suspend operation:

1. Set PROCTL[SABGREQ] to pause the current data transfer at block gap.
2. After IRQSTAT[BGE] is set, send the suspend command to suspend the active function. XFERTYP[CMDTYP] field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The XFERTYP[CMDTYP] of this command must be 2'b01, so the SDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the SDHC stops driving DAT2 and goes to the Idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register for internal DMA operation, and the block attribute register.
6. Begin operation for another function on the SDIO card.

#### 56.6.3.3.2 Resume

To resume the data transfer, a resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step 5 of the suspend operation above.

2. Send the resume command. In the transfer type register, all fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume, except the CMDTYP is set to 2'b10.
3. If the resume command has responded, the data transfer will be resumed.

#### 56.6.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 KB address aligned).
3. If necessary, create a link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1–3.
4. Repeat steps 1–3 until all descriptors are created.
5. In the last descriptor, set the end flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the BLKATTR register.
6. Set the DSADDR register to the address of the first descriptor and set the PROCTL[DMAS] field to 01 to select the ADMA.
7. Issue a write or read command with XFERTYP[DMAEN] set to 1.

Steps 1–5 are independent of step 6, so step 6 can finish before steps 1–5. Regarding the descriptor configuration, do not to use the link descriptor, as it requires extra system memory access.

#### 56.6.3.5 Transfer error

This section discusses the handling of transfer errors.

### 56.6.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. Discard the following data blocks and retransfer the block from the corrupted one.

For a multi-block transfer, the host driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the XFERTYP[AC12EN] and BCEND bits are set, the SDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an auto CMD12 will be sent by the SDHC. In this case, the driver shall re-send or re-obtain the last block with a single block transfer.

### 56.6.3.5.2 Internal DMA error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the system bus, the DMA operation is aborted and DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Reading the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Reading the BLKCNT field of the block attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the block attribute register does not change, so this method does not work.

When a DMA error occurs, abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

### 56.6.3.5.3 ADMA error

There are three kinds of possible ADMA errors: transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and retransfer from the place of interruption.

- **Transfer error:** May occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
- **Invalid descriptor error:** For such errors, retrieve the transfer context, reset for the data part, and recreate the descriptor chain from the invalid descriptor, and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- **Data-length mismatch error:** It is similar to recover from this error. The host driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

#### 56.6.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and XFERTYP[AC12EN] is set when the data transfer is initiated by the data command, the SDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, the driver can deal with the situations in the following manner:

1. **Auto CMD12 response time-out:** It is not certain whether the command is accepted by the card or not. The driver should clear the IRQSTAT[AC12E] bits and resend the CMD12 until it is accepted by the card.
2. **Auto CMD12 response CRC error:** Because the card responds to the CMD12, the card will abort the transfer. The driver may ignore the error and clear the IRQSTAT[AC12E] bit.
3. **Auto CMD12 conflict error or not sent:** The command is not sent, so the driver shall send a CMD12 manually.

#### 56.6.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. For the CE-ATA card, it can be a pulse on the CMD line to inform the host controller that the command and its response is finished, and it is possible that some additional external interrupt behaviors are defined. The SDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the SDHC, and the host system is informed by the SDHC asserting the SDHC interrupt line, the interrupt service from the host driver is called.

Because the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before IRQSTAT[CINT] is cleared by written 1. See [Card interrupt handling](#) for the card interrupt handling flow.

## 56.6.4 Switch function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC specifications. The high-speed timing mode for all card devices was also recently defined in various card specifications. To enable these new features, a switch command shall be issued by the host driver.

For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6, with the mnemonic symbol as SWITCH\_FUNC. For MMC cards (and CE-ATA over MMC interface), the high-speed mode is queried by a CMD8 and enabled by a CMD6, with the mnemonic symbol as SWITCH.

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

### 56.6.4.1 Query, enable and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
```

```

send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
    
```

### 56.6.4.2 Query, enable, and disable SD high-speed mode

```

enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
    
```

### 56.6.4.3 Query, enable, and disable MMC high-speed mode

```

enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
}
    
```

## Initialization/application of SDHC

```

if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}

```

### 56.6.4.4 Set MMC bus width

```

change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}

```

## 56.6.5 ADMA operation

This section presents code examples for ADMA operation.

### 56.6.5.1 ADMA1 operation

```

Set_adma1_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 4KB align.
        Set 'Set' type descriptor;
        {
            Set Act bits to 01;
            Set [31:12] bits data length (byte unit);
        }
        Set 'Tran' type descriptor;
        {
            Set Act bits to 10;
            Set [31:12] bits address (4KB align);
        }
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to 11;
        Set [31:12] bits the next descriptor address (4KB align);
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set End bit to 1;
    }
    if (to generate interrupt for this descriptor) {
        Set Int bit to 1;
    }
    Set Valid bit to 1;
}

```

## 56.6.5.2 ADMA2 operation

```

Set_adma2_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
        Set higher 32-bit of descriptor for this data transfer initial address;
        Set [31:16] bits data length (byte unit);
        Set Act bits to '10';
    }
    else if (to fetch descriptor at non-continuous address) {
        Set Act bits to '11';
        // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
        Set higher 32-bit of descriptor for the next descriptor address;
    }
    else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set 'End' bit '1';
    }
    if (to generate interrupt for this descriptor) {
        Set 'Int' bit '1';
    }
    Set the 'Valid' bit to '1';
}

```

## 56.6.6 Fast boot operation

This section discusses fast boot operations.

### 56.6.6.1 Normal fast boot flow

1. Software needs to configure SYSCTL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1, MMCBOOT[BOOTMODE] to 0, and MMCBOOT[BOOTACK] to select the ack mode or not. If sending through DMA mode, software needs to configure MMCBOOT[AUTOSABGEN] to enable automatically stop at block gap feature, and MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no.
4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG to set argument if needed (no need in normal fast boot).

6. Software needs to configure XFERTYP register to start the boot process. In Normal Boot mode, XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCEN], XFERTYP[AC12EN], XFERTYP[BCEN] and XFERTYP[DMAEN] are kept default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. Note XFERTYP[DMAEN] must be configured as 0 in polling mode. And if XFERTYP[BCEN] is configured as 1, better to configure BLKATTR[BLKSIZE] to the max value.
7. When the step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMCBOOT[BOOTEN] to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out, software needs to decide the data read is finished and then configure MMCBOOT[BOOTEN] to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

### 56.6.6.2 Alternative fast boot flow

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT [BOOTEN] to 1, MMCBOOT [BOOTMODE] to 1, and MMCBOOT [BOOTACK] to select the ack mode or not. If sending through DMA mode, it also needs to configure MMCBOOT [AUTOSABGEN] to enable automatically stop at block gap feature. And needs to configure MMCBOOT [DTCVACK] to select the ack timeout value according to the sd clk frequency.
3. Software then needs to configure BLKATTR register to set block size/no.
4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure XFERTYP register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCEN, AC12EN, BCEN, and DMAEN are kept default value. DPSEL bit

is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in Polling mode, it is better to configure blk no in Block Attributes Register to the max value.

7. When step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time out (ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMCBOOT[BOOTEN] to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMCBOOT[BOOTEN] to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then begin the normal process.

### 56.6.6.3 Fast boot application case in DMA mode

In the boot application case, because the image destination and the image size are contained in the beginning of the image, switching DMA parameters on the fly during MMC fast boot is required.

In fast boot, host can use ADMA2 (advanced DMA2) with two destinations.

The detail flow:

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1; and MMCBOOT[BOOTMODE] to 0 (normal fast boot), to 1(alternative boot); and MMCBOOT[BOOTACK] to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] to set the VAULE1 (value of block count that need to trans first time), so that host will stop at block gap when card block counter is equal to this value. And it needs to configure MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequency.

3. Software then needs to configure BLKATTR register to set block size/no. In DMA mode, it is better to set block number to the max value(16'hffff).
4. Software needs to configure PROCTL[DTW].
5. Software enables ADMA2 by configuring PROCTL[DMAS].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (that is, in IRAM, at least 6 words). The first pair descriptor define the start address (IRAM) and data length(512byte\*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writable), data length is suggest to set 1~2 word (record as VAULE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.
7. Software needs to configure CMDARG register to set argument to 0xFFFFFFFFFA in alternative fast boot, and doesn't need to be set in normal fast boot.
8. Software needs to configure XFERTYP register to start the boot process . XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN], and XFERTYP[DMAEN] are kept at default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. XFERTYP[DMAEN] is configured as 1 in DMA mode. And if XFERTYP[BCEN] is configured as 1, better to configure blk no in BLKATTR register to the max value.
9. When step 8 is configured, boot process will begin, the first VAULE1 block number data has transfer. Software needs to poll IRQSTAT[TC] bit to determine first transfer is end. Also software needs to poll IRQSTAT[BGE] bit to determine if first transfer stop at block gap.
10. When IRQSTAT[TC] and IRQSTAT[BGE] bits are 1, . SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember set the last descriptor with END.
11. Software needs to configure MMCBOOT register (offset 0xc4) again. Set MMCBOOT[BOOTEN] bit to 1; and MMCBOOT[BOOTMODE] bit to 0 (normal fast boot), to 1 (alternative boot); and MMCBOOT[BOOTACK] bit to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] bit to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] bit to set the (VAULE1+1+VAULE3), so that host

will stop at block gap when card block counter is equal to this value. And need to configure MMCBOOT[DTOCVACK] bit to select the ack timeout value according to the sd clk frequency.

12. Software needs to clear IRQSTAT[TC] and IRQSTAT[BGE] bit. And software need to clear PROCTL[SABGREQ], and set PROCTL[CREQ] to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software needs to poll IRQSTAT[BGE] bit to determine if the fast boot is over.

**Note**

1. When ADMA boot flow is started, for SDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 words data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

### 56.6.7 Commands for MMC/SD/SDIO/CE-ATA

The following table lists the commands for the MMC/SD/SDIO/CE-ATA cards.

See the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the Multimediacard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DAT
- Addressed (point-to-point) data transfer commands (adtc)

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards**

| CMD INDEX | Type | Argument          | Resp | Abbreviation  | Description                                       |
|-----------|------|-------------------|------|---------------|---|
| CMD0      | bc   | [31:0] stuff bits | -    | GO_IDLE_STATE | Resets all MMC and SD memory cards to idle state. |

*Table continues on the next page...*

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards (continued)**

| CMD INDEX         | Type | Argument   | Resp            | Abbreviation               | Description  |
|-------------------|------|--|-----------------|----------------------------|--|
| CMD1              | bcr  | [31:0] OCR without busy  | R3              | SEND_OP_COND               | Asks all MMC and SD memory cards in idle state to send their operation conditions register contents in the response on the CMD line.   |
| CMD2              | bcr  | [31:0] stuff bits  | R2              | ALL_SEND_CID               | Asks all cards to send their CID numbers on the CMD line.  |
| CMD3 <sup>1</sup> | ac   | [31:6] RCA<br>[15:0] stuff bits  | R1<br>R6 (SDIO) | SET/<br>SEND_RELATIVE_ADDR | Assigns relative address to the card.  |
| CMD4              | bc   | [31:0] DSR<br>[15:0] stuff bits  | -               | SET_DSR                    | Programs the DSR of all cards.   |
| CMD5              | bc   | [31:0] OCR without busy  | R4              | IO_SEND_OP_COND            | Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.  |
| CMD6 <sup>2</sup> | adtc | [31] Mode<br>0: Check function<br>1: Switch function [30:8]<br>Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF)<br>[7:4] Function group1 for command system<br>[3:0] Function group2 for access mode | R1              | SWITCH_FUNC                | Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.  |
| CMD6 <sup>3</sup> | ac   | [31:26] Set to 0<br>[25:24] Access<br>[23:16] Index<br>[15:8] Value<br>[7:3] Set to 0<br>[2:0] Cmd Set   | R1b             | SWITCH                     | Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.  |
| CMD7              | ac   | [31:6] RCA<br>[15:0] stuff bits  | R1b             | SELECT/<br>DESELECT_CARD   | Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all. |
| CMD8              | adtc | [31:0] stuff bits  | R1              | SEND_EXT_CSD               | The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.  |

Table continues on the next page...

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards (continued)**

| CMD INDEX | Type     | Argument                        | Resp | Abbreviation         | Description   |
|-----------|----------|---------------------------------|------|----------------------|---|
| CMD9      | ac       | [31:6] RCA<br>[15:0] stuff bits | R2   | SEND_CSD             | Addressed card sends its card-specific data (CSD) on the CMD line.  |
| CMD10     | ac       | [31:6] RCA<br>[15:0] stuff bits | R2   | SEND_CID             | Addressed card sends its card-identification (CID) on the CMD line.   |
| CMD11     | adtc     | [31:0] data address             | R1   | READ_DAT_UNTIL_STOP  | Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.                                |
| CMD12     | ac       | [31:0] stuff bits               | R1b  | STOP_TRANSMISSION    | Forces the card to stop transmission.   |
| CMD13     | ac       | [31:6] RCA<br>[15:0] stuff bits | R1   | SEND_STATUS          | Addressed card sends its status register.   |
| CMD14     | Reserved |                                 |      |                      |   |
| CMD15     | ac       | [31:6] RCA<br>[15:0] stuff bits | -    | GO_INACTIVE_STATE    | Sets the card to inactive state to protect the card stack against communication breakdowns.                                       |
| CMD16     | ac       | [31:0] block length             | R1   | SET_BLOCKLEN         | Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD. |
| CMD17     | adtc     | [31:0] data address             | R1   | READ_SINGLE_BLOCK    | Reads a block of the size selected by the SET_BLOCKLEN command.   |
| CMD18     | adtc     | [31:0] data address             | R1   | READ_MULTIPLE_BLOCK  | Continuously transfers data blocks from card to host until interrupted by a stop command.   |
| CMD19     | Reserved |                                 |      |                      |   |
| CMD20     | adtc     | [31:0] data address             | R1   | WRITE_DAT_UNTIL_STOP | Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.                               |
| CMD21-23  | Reserved |                                 |      |                      |   |
| CMD24     | adtc     | [31:0] data address             | R1   | WRITE_BLOCK          | Writes a block of the size selected by the SET_BLOCKLEN command.  |
| CMD25     | adtc     | [31:0] data address             | R1   | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows.   |

Table continues on the next page...

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards (continued)**

| CMD INDEX | Type     | Argument                          | Resp | Abbreviation          | Description   |
|-----------|----------|-----------------------------------|------|-----------------------|---|
| CMD26     | adtc     | [31:0] stuff bits                 | R1   | PROGRAM_CID           | Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer. |
| CMD27     | adtc     | [31:0] stuff bits                 | R1   | PROGRAM_CSD           | Programming of the programmable bits of the CSD.  |
| CMD28     | ac       | [31:0] data address               | R1b  | SET_WRITE_PROT        | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).   |
| CMD29     | ac       | [31:0] data address               | R1b  | CLR_WRITE_PROT        | If the card provides write protection features, this command clears the write protection bit of the addressed group.  |
| CMD30     | adtc     | [31:0] write protect data address | R1   | SEND_WRITE_PROT       | If the card provides write protection features, this command asks the card to send the status of the write protection bits.   |
| CMD31     | Reserved |                                   |      |                       |   |
| CMD32     | ac       | [31:0] data address               | R1   | TAG_SECTOR_START      | Sets the address of the first sector of the erase group.  |
| CMD33     | ac       | [31:0] data address               | R1   | TAG_SECTOR_END        | Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.   |
| CMD34     | ac       | [31:0] data address               | R1   | UNTAG_SECTOR          | Removes one previously selected sector from the erase selection.  |
| CMD35     | ac       | [31:0] data address               | R1   | TAG_ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase.  |
| CMD36     | ac       | [31:0] data address               | R1   | TAG_ERASE_GROUP_END   | Sets the address of the last erase group within a continuous range to be selected for erase.  |
| CMD37     | ac       | [31:0] data address               | R1   | UNTAG_ERASE_GROUP     | Removes one previously selected erase group from the erase selection.   |

Table continues on the next page...

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards (continued)**

| CMD INDEX | Type     | Argument   | Resp | Abbreviation   | Description   |
|-----------|----------|--|------|----------------|---|
| CMD38     | ac       | [31:0] stuff bits  | R1b  | ERASE          | Erase all previously selected sectors.  |
| CMD39     | ac       | [31:0] RCA<br>[15] register write flag<br>[14:8] register address<br>[7:0] register data | R4   | FAST_IO        | Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard. |
| CMD40     | bcr      | [31:0] stuff bits  | R5   | GO_IRQ_STATE   | Sets the system into interrupt mode.  |
| CMD41     | Reserved |  |      |                |   |
| CDM42     | adtc     | [31:0] stuff bits  | R1b  | LOCK_UNLOCK    | Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.   |
| CMD43~51  | Reserved |  |      |                |   |
| CMD52     | ac       | [31:0] stuff bits  | R5   | IO_RW_DIRECT   | Access a single register within the total 128k of register space in any I/O function.   |
| CMD53     | ac       | [31:0] stuff bits  | R5   | IO_RW_EXTENDED | Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.   |
| CMD54     | Reserved |  |      |                |   |
| CMD55     | ac       | [31:16] RCA<br>[15:0] stuff bits   | R1   | APP_CMD        | Indicates to the card that the next command is an application specific command rather than a standard command.  |
| CMD56     | adtc     | [31:1] stuff bits<br>[0]: RD/WR  | R1b  | GEN_CMD        | Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.  |
| CMD57~59  | Reserved |  |      |                |   |

Table continues on the next page...

**Table 56-37. Commands for MMC/SD/SDIO/CE-ATA cards (continued)**

| CMD INDEX            | Type     | Argument  | Resp | Abbreviation           | Description  |
|----------------------|----------|---|------|------------------------|--|
| CMD60                | adtc     | [31] WR<br>[30:24] stuff bits<br>[23:16] address<br>[15:8] stuff bits<br>[7:0] byte count | R1b  | RW_MULTIPLE_REGISTER   | CE-ATA devices contain a set of Status and Control registers that begin at register offset 80h. These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers. |
| CMD61                | adtc     | [31] WR<br>[30:16] stuff bits<br>[15:0] data unit count                                   | R1b  | RW_MULTIPLE_BLOCK      | The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer for the ATA command.  |
| CMD62~63             | Reserved |   |      |                        |  |
| ACMD6 <sup>4</sup>   | ac       | [31:2] stuff bits [1:0] bus width   | R1   | SET_BUS_WIDTH          | Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.   |
| ACMD13 <sup>5</sup>  | adtc     | [31:0] stuff bits   | R1   | SD_STATUS              | Send the SD memory card status.  |
| ACMD22 <sup>6</sup>  | adtc     | [31:0] stuff bits   | R1   | SEND_NUM_WR_SECTORS    | Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.   |
| ACMD23 <sup>7</sup>  | ac       |   | R1   | SET_WR_BLK_ERASE_COUNT | -  |
| ACMD41 <sup>8</sup>  | bcr      | [31:0] OCR  | R3   | SD_APP_OP_COND         | Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.  |
| ACMD42 <sup>9</sup>  | ac       |   | R1   | SET_CLR_CARD_DETECT    | -  |
| ACMD51 <sup>10</sup> | adtc     | [31:0] stuff bits   | R1   | SEND_SCR               | Reads the SD Configuration Register (SCR).   |

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards as well as for CE-ATA cards over the MMC interface. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in [Table 56-38](#).
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

5. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
6. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
7. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
8. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
9. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
10. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown in the following table.

**Table 56-38. EXT\_CSD Access Modes**

| Bits | Access Name | Operation   |
|------|-------------|---|
| 00   | Command Set | The command set is changed according to the Cmd Set field of the argument             |
| 01   | Set Bits    | The bits in the pointed byte are set, according to the 1 bits in the Value field.     |
| 10   | Clear Bits  | The bits in the pointed byte are cleared, according to the 1 bits in the Value field. |
| 11   | Write Byte  | The Value field is written into the pointed byte.                                     |

## 56.7 Software restrictions

Software for the SDHC must observe the following restrictions.

### 56.7.1 Initialization active

The driver cannot set SYSCTL[INITA] when any of the command line or data lines is active, so the driver must ensure both PRSSTAT[CDIHB] and PRSSTAT[CIHB] bits are cleared. To auto clear SYSCTL[INITA], SYSCTL[SDCLKEN] must be 1, otherwise no clocks can go out to the card and SYSCTL[INITA] will never clear.

### 56.7.2 Software polling procedure

For polling read or write, when the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register. Moreover, if the block size is not the times of the value in watermark level register, read and write respectively, the software must access exactly the remained number of words at the end of each block.

For example, for read operation, if the WML[RDWML] is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 56.7.3 Suspend operation

To suspend the data transfer, the software must inform SDHC that the suspend command is successfully accepted. To achieve this, after the suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (XFERTYP[CMDTYP] bits set as 01) to inform SDHC that the transfer is suspended.

If software needs resume the suspended transfer, it should read the value in BLKATTR[BLKCNT] to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such suspend command, SDHC will regard the current transfer as aborted and change BLKATTR[BLKCNT] to its original value, instead of keeping the remained number of blocks.

### 56.7.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be times of 4.

### 56.7.5 (A)DMA address setting

To configure ADMA1/ADMA2/DMA address register, when TC[IRQSTAT] is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must ensure that TC[IRQSTAT] is cleared prior to configuring ADMA1/ADMA2/DMA address register.

### 56.7.6 Data port access

Data port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or external DMA. Otherwise the data would be corrupted inside the SDHC buffer.

### 56.7.7 Change clock frequency

SDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear `SYSCTL[SDCLKEN]` when changing clock divisor value and set `SYSCTL[SDCLKEN]` to 1 after `PRSTAT[SDSTB]` is 1 again.

### 56.7.8 Multi-block read

For predefined multi-block read operation, that is, the number of blocks to read has been defined by previous `CMD23` for MMC, or predefined number of blocks in `CMD53` for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual `CMD12/CMD52`, is still required by SDHC after the pre-defined number of blocks are done, to drive the internal start response timeout. Manually sending an abort command with `XFERTYP[RSPTYP]` both bits cleared is recommended.

# Chapter 57

## Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

### 57.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The I<sup>2</sup>S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I<sup>2</sup>S, AC97, TDM, and codec/DSP interfaces.

#### 57.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

#### NOTE

**About data lines and audio channels:** Typically there are one or more data lines for TX and RX sides of the SAI peripheral, depending on the device's design. Each SAI data line may support 1 - 32 audio channels (or audio words).

- Transmitter with independent bit clock and frame sync supporting 2 data lines
- Receiver with independent bit clock and frame sync supporting 2 data lines
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

## 57.1.2 Block diagram

The following block diagram also shows the module clocks.

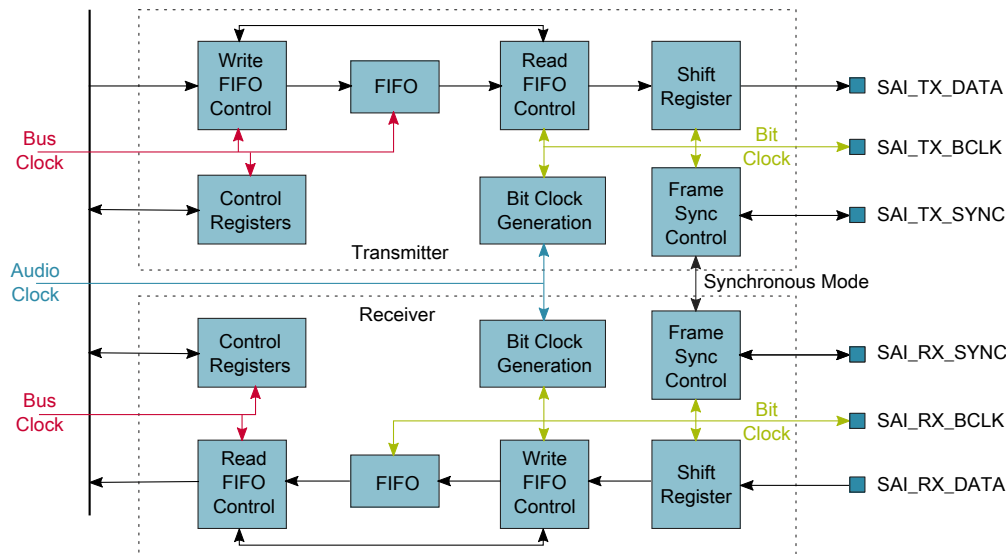

Figure 57-1. I²S/SAI block diagram

## 57.1.3 Modes of operation

The module operates in these MCU power modes: Run mode, stop modes, low-leakage modes, and Debug mode.

### 57.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

### 57.1.3.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 57.1.3.3 Low-leakage modes

When entering low-leakage modes, the Stop Enable (TCSR[STOPE] and RCSR[STOPE]) bits are ignored and the SAI is disabled after completing the current transmit and receive Frames. Entry into stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 57.1.3.4 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 57.2 External signals

| Name             | Function   | I/O |
|------------------|--|-----|
| SAI_TX_BCLK      | Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.   | I/O |
| SAI_TX_SYNC      | Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| SAI_TX_DATA[1:0] | Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.  | O   |
| SAI_RX_BCLK      | Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.  | I/O |

*Table continues on the next page...*

**memory map and register definition**

| Name             | Function  | I/O |
|------------------|---|-----|
| SAI_RX_SYNC      | Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated. | I/O |
| SAI_RX_DATA[1:0] | Receive Data. The receive data is sampled synchronously by the bit clock.   | I   |
| SAI_MCLK         | Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.   | I/O |

## 57.3 Memory map and register definition

A read or write access to an address from offset 0x108 and above will result in a bus error.

### I2S memory map

| Absolute address (hex) | Register name                                     | Width (in bits) | Access                | Reset value | Section/page                 |
|------------------------|---|-----------------|-----------------------|-------------|------------------------------|
| 4002_F000              | SAI Transmit Control Register (I2S0_TCSR)         | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.1/2003</a>  |
| 4002_F004              | SAI Transmit Configuration 1 Register (I2S0_TCR1) | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.2/2006</a>  |
| 4002_F008              | SAI Transmit Configuration 2 Register (I2S0_TCR2) | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.3/2006</a>  |
| 4002_F00C              | SAI Transmit Configuration 3 Register (I2S0_TCR3) | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.4/2008</a>  |
| 4002_F010              | SAI Transmit Configuration 4 Register (I2S0_TCR4) | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.5/2009</a>  |
| 4002_F014              | SAI Transmit Configuration 5 Register (I2S0_TCR5) | 32              | R/W                   | 0000_0000h  | <a href="#">57.3.6/2010</a>  |
| 4002_F020              | SAI Transmit Data Register (I2S0_TDR0)            | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">57.3.7/2011</a>  |
| 4002_F024              | SAI Transmit Data Register (I2S0_TDR1)            | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">57.3.7/2011</a>  |
| 4002_F040              | SAI Transmit FIFO Register (I2S0_TFR0)            | 32              | R                     | 0000_0000h  | <a href="#">57.3.8/2011</a>  |
| 4002_F044              | SAI Transmit FIFO Register (I2S0_TFR1)            | 32              | R                     | 0000_0000h  | <a href="#">57.3.8/2011</a>  |

### 57.3.1 SAI Transmit Control Register (I2Sx\_TCSR)

Address: Base address + 0h offset

I2Sx\_TCSR field descriptions

| Field       | Description   |
|-------------|---|
| 31<br>TE    | <p>Transmitter Enable</p> <p>Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Transmitter is disabled.<br/>1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.</p> |
| 30<br>STOPE | <p>Stop Enable</p> <p>Configures transmitter operation in Stop mode. This field is ignored and the transmitter is disabled in all low-leakage stop modes.</p> <p>0 Transmitter disabled in Stop mode.<br/>1 Transmitter enabled in Stop mode.</p>   |
| 29<br>DBGE  | <p>Debug Enable</p>   |

Table continues on the next page...

### I2Sx\_TCSR field descriptions (continued)

| Field             | Description   |
|-------------------|---|
|                   | <p>Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode.</p> <p>0 Transmitter is disabled in Debug mode, after completing the current frame.<br/>1 Transmitter is enabled in Debug mode.</p>  |
| 28<br>BCE         | <p>Bit Clock Enable</p> <p>Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Transmit bit clock is disabled.<br/>1 Transmit bit clock is enabled.</p> |
| 27–26<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 25<br>FR          | <p>FIFO Reset</p> <p>Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set.</p> <p>0 No effect.<br/>1 FIFO reset.</p>   |
| 24<br>SR          | <p>Software Reset</p> <p>When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.</p> <p>0 No effect.<br/>1 Software reset.</p>   |
| 23–21<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>   |
| 20<br>WSF         | <p>Word Start Flag</p> <p>Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.</p> <p>0 Start of word not detected.<br/>1 Start of word detected.</p>   |
| 19<br>SEF         | <p>Sync Error Flag</p> <p>Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.</p> <p>0 Sync error not detected.<br/>1 Frame sync error detected.</p>  |
| 18<br>FEF         | <p>FIFO Error Flag</p> <p>Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag.</p> <p>0 Transmit underrun not detected.<br/>1 Transmit underrun detected.</p>  |

I2Sx\_TCR2 field descriptions

| Field         | Description  |
|---------------|--|
| 31–30<br>SYNC | <p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation.</p> <p>00 Asynchronous mode.<br/>01 Synchronous with receiver.<br/>10 Synchronous with another SAI transmitter.<br/>11 Synchronous with another SAI receiver.</p>  |
| 29<br>BCS     | <p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).</p> <p>This field has no effect when synchronous to another SAI peripheral.</p> <p>0 Use the normal bit clock source.<br/>1 Swap the bit clock source.</p>   |
| 28<br>BCI     | <p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral .</p> <p>0 No effect.<br/>1 Internal logic is clocked as if bit clock was externally generated.</p> |
| 27–26<br>MSEL | <p>MCLK Select</p> <p>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.</p> <p><b>NOTE:</b> Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option.</p> <p>00 Bus Clock selected.<br/>01 Master Clock (MCLK) 1 option selected.<br/>10 Master Clock (MCLK) 2 option selected.<br/>11 Master Clock (MCLK) 3 option selected.</p>   |
| 25<br>BCP     | <p>Bit Clock Polarity</p> <p>Configures the polarity of the bit clock.</p>   |

### I2Sx\_TCR5 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–29<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 28–24<br>WNW      | Word N Width<br>Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.                    |
| 23–21<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 20–16<br>WOW      | Word 0 Width<br>Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. |
| 15–13<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 12–8<br>FBT       | First Bit Shifted   |

Table continues on the next page...

### I2Sx\_TCR5 field descriptions (continued)

| Field           | Description  |
|-----------------|--|
|                 | Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. |
| 7-0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.  |

### 57.3.7 SAI Transmit Data Register (I2Sx\_TDRn)

Address: Base address + 20h offset + (4d × i), where i=0d to 1d

#### I2Sx\_TDRn field descriptions

| Field             | Description   |
|-------------------|---|
| 31-0<br>TDR[31:0] | Transmit Data Register<br><br>The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored. |

### 57.3.8 SAI Transmit FIFO Register (I2Sx\_TFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 1d

### I2Sx\_TFRn field descriptions

| Field             | Description   |
|-------------------|---|
| 31<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 30–20<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 19–16<br>WFP      | Write FIFO Pointer<br>FIFO write pointer for transmit data channel.                     |
| 15–4<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 3–0<br>RFP        | Read FIFO Pointer<br>FIFO read pointer for transmit data channel.                       |

### 57.3.9 SAI Transmit Mask Register (I2Sx\_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

### I2Sx\_TMR field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>TWM | Transmit Word Mask<br>Configures whether the transmit word is masked (transmit data pin tristated and transmit data not read from FIFO) for the corresponding word in the frame.<br><br>0 Word N is enabled.<br>1 Word N is masked. The transmit data pins are tri-stated when masked. |

### 57.3.10 SAI Receive Control Register (I2Sx\_RCSR)

Address: Base address + 80h offset

|       |    |    |    |      |      |      |      |      |    |    |    |     |     |     |      |      |
|-------|----|----|----|------|------|------|------|------|----|----|----|-----|-----|-----|------|------|
| Bit   | 31 | 30 | 29 | 28   | 27   | 26   | 25   | 24   | 23 | 22 | 21 | 20  | 19  | 18  | 17   | 16   |

#### I2Sx\_RCR2 field descriptions

| Field         | Description      |
|---------------|------------------|
| 31–30<br>SYNC | Synchronous Mode |

Table continues on the next page...

I2Sx\_RCR2 field descriptions (continued)

| Field         | Description  |
|---------------|--|
|               | <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation.</p> <p>00 Asynchronous mode.<br/>           01 Synchronous with transmitter.<br/>           10 Synchronous with another SAI receiver.<br/>           11 Synchronous with another SAI transmitter.</p>   |
| 29<br>BCS     | <p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC).</p> <p>When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC).</p> <p>This field has no effect when synchronous to another SAI peripheral.</p> <p>0 Use the normal bit clock source.<br/>           1 Swap the bit clock source.</p>  |
| 28<br>BCI     | <p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral .</p> <p>0 No effect.<br/>           1 Internal logic is clocked as if bit clock was externally generated.</p> |
| 27-26<br>MSEL | <p>MCLK Select</p> <p>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.</p> <p><b>NOTE:</b> Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option.</p> <p>00 Bus Clock selected.<br/>           01 Master Clock (MCLK) 1 option selected.<br/>           10 Master Clock (MCLK) 2 option selected.<br/>           11 Master Clock (MCLK) 3 option selected.</p>  |
| 25<br>BCP     | <p>Bit Clock Polarity</p> <p>Configures the polarity of the bit clock.</p> <p>0 Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge.<br/>           1 Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.</p>  |

### I2Sx\_RCR5 field descriptions

| Field             | Description   |
|-------------------|---|
| 31–29<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 28–24<br>WNW      | Word N Width<br>Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.                    |
| 23–21<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 20–16<br>WOW      | Word 0 Width<br>Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame. |
| 15–13<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.   |
| 12–8<br>FBT       | First Bit Shifted   |

Table continues on the next page...

### I2Sx\_RCR5 field descriptions (continued)

| Field           | Description   |
|-----------------|---|
|                 | Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First. |

### 57.3.16 SAI Receive Data Register (I2Sx\_RDRn)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: Base address + A0h offset + (4d × i), where i=0d to 1d

### I2Sx\_RDRn field descriptions

| Field             | Description  |
|-------------------|--|
| 31–0<br>RDR[31:0] | Receive Data Register<br><br>The corresponding RCR3[RCE] bit must be set before accessing the channel's receive data register. Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored. |

### 57.3.17 SAI Receive FIFO Register (I2Sx\_RFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + C0h offset + (4d × i), where i=0d to 1d

### 57.3.18 SAI Receive Mask Register (I2Sx\_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: Base address + E0h offset

**I2Sx\_RMR field descriptions**

| Field       | Description  |
|-------------|--|
| 31–0<br>RWM | <p>Receive Word Mask</p> <p>Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled.<br/>1 Word N is masked.</p> |

**57.3.19 SAI MCLK Control Register (I2Sx\_MCR)**

The MCLK Control Register (MCR) controls the clock source and direction of the audio master clock.

Address: Base address + 100h offset

**I2Sx\_MCR field descriptions**

| Field     | Description  |
|-----------|--|
| 31<br>DUF | <p>Divider Update Flag</p> <p>Provides the status of on-the-fly updates to the MCLK divider ratio.</p> <p>0 MCLK divider ratio is not being updated currently.<br/>1 MCLK divider ratio is updating on-the-fly. Further updates to the MCLK divider ratio are blocked while this flag remains set.</p> |
| 30<br>MOE | <p>MCLK Output Enable</p> <p>Enables the MCLK divider and configures the MCLK signal pin as an output. When software clears this field, it remains set until the MCLK divider is fully disabled.</p>   |

## I2Sx\_MDR field descriptions (continued)

| Field | Description |
|-------|-------------|
|-------|-------------|

## 57.4 Functional description

This section provides a complete functional description of the block.

### 57.4.1 SAI clocking

The SAI clocks include:

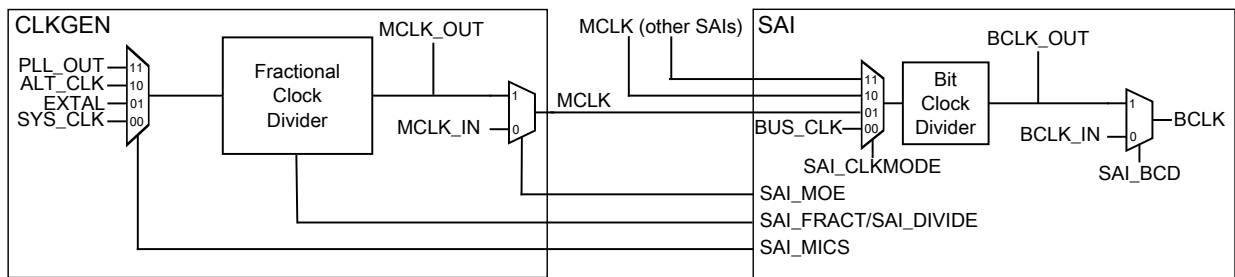

- The audio master clock
- The bit clock
- The bus clock

#### 57.4.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

Each SAI peripheral can control the input clock selection, pin direction and divide ratio of one audio master clock. The input clock selection and pin direction cannot be altered if an SAI module using that audio master clock has been enabled. The MCLK divide ratio can be altered while an SAI is using that master clock, although the change in the divide ratio takes several cycles. MCR[DUF] can be polled to determine when the divide ratio change has completed.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated. A typical implementation appears in the following figure.

**Figure 57-86. SAI master clock generation**

The MCLK fractional clock divider uses both clock edges from the input clock to generate a divided down clock that will approximate the output frequency, but without creating any new clock edges. Configuring FRACT and DIVIDE to the same value will result in a divide by 1 clock, while configuring FRACT higher than DIVIDE is not supported. The duty cycle can range from 66/33 when FRACT is set to one less than DIVIDE down to 50/50 for integer divide ratios, and will approach 50/50 for large non-integer divide ratios. There is no cycle to cycle jitter or duty cycle variance when the divide ratio is an integer or half integer, otherwise the divider output will oscillate between the two divided frequencies that are the closest integer or half integer divisors of the divider input clock frequency. The maximum jitter is therefore equal to half the divider input clock period, since both edges of the input clock are used in generating the divided clock.

### 57.4.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

### 57.4.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

#### NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

### 57.4.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

#### 57.4.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

#### 57.4.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

### 57.4.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripherals.

#### 57.4.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

#### 57.4.3.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

#### 57.4.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

#### 57.4.5 Data FIFO

Each transmit and receive channel includes a FIFO of size  $8 \times 32$ -bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

### 57.4.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 57-87](#) for LSB First configurations and [Figure 57-88](#) for MSB First configurations.

Figure 57-87. SAI first bit shifted, LSB first

Figure 57-88. SAI first bit shifted, MSB first

### 57.4.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

### 57.4.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

### 57.4.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

### 57.4.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

### 57.4.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### 57.4.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

#### **57.4.7.4 Sync error flag**

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

#### **57.4.7.5 Word start flag**

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

# Chapter 58

## General-Purpose Input/Output (GPIO)

### 58.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface for maximum pin performance. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

#### 58.1.1 Features

- Features of the GPIO module include:
  - Port Data Input register visible in all digital pin-multiplexing modes
  - Port Data Output register with corresponding set/clear/toggle registers
  - Port Data Direction register
  - Zero wait state access to GPIO registers through IOPORT

#### NOTE

The GPIO module is clocked by system clock.

## 58.1.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 58-1. Modes of operation**

| Modes of operation | Description                        |
|--------------------|------------------------------------|
| Run                | The GPIO module operates normally. |
| Wait               | The GPIO module operates normally. |
| Stop               | The GPIO module is disabled.       |
| Debug              | The GPIO module operates normally. |

## 58.1.3 GPIO signal descriptions

**Table 58-2. GPIO signal descriptions**

| GPIO signal descriptions | Description                  | I/O |
|--------------------------|------------------------------|-----|
| PORTA31–PORTA0           | General-purpose input/output | I/O |
| PORTB31–PORTB0           | General-purpose input/output | I/O |
| PORTC31–PORTC0           | General-purpose input/output | I/O |
| PORTD31–PORTD0           | General-purpose input/output | I/O |
| PORTE31–PORTE0           | General-purpose input/output | I/O |
| PORTF31–PORTF0           | General-purpose input/output | I/O |

### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

### 58.1.3.1 Detailed signal description

**Table 58-3. GPIO interface-detailed signal descriptions**

| Signal   | I/O | Description                  |  |
|--|-----|------------------------------|--|
| PORTA31–PORTA0<br>PORTB31–PORTB0<br>PORTC31–PORTC0<br>PORTD31–PORTD0<br>PORTE31–PORTE0 | I/O | General-purpose input/output |  |
|  |     | State meaning                | Asserted: The pin is logic 1.<br>Deasserted: The pin is logic 0.   |
|  |     | Timing                       | Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.<br><br>Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. |

#### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 58.2 Memory map and register definition

Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

#### GPIO memory map

| Absolute address (hex) | Register name                            | Width (in bits) | Access                | Reset value | Section/page                |
|------------------------|--|-----------------|-----------------------|-------------|-----------------------------|

| 31–0<br>PTTO | <p>Port Toggle Output</p> <p>Writing to this register will update the contents of the corresponding bit in the PDOR as follows:</p> <p>0 Corresponding bit in PDORn does not change.</p> <p>1 Corresponding bit in PDORn is set to the inverse of its existing logic state.</p> |

### 58.2.5 Port Data Input Register (GPIOx\_PDIR)

#### NOTE

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 10h offset

#### GPIOx\_PDIR field descriptions

| Field       | Description  |
|-------------|--|
| 31–0<br>PDI | <p>Port Data Input</p> <p>Reads 0 at the unimplemented pins for a particular device. Pins that are not configured for a digital function read 0. If the Port Control and Interrupt module is disabled, then the corresponding bit in PDIR does not update.</p> <p>0 Pin logic level is logic 0, or is not configured for use by digital function.</p> <p>1 Pin logic level is logic 1.</p> |

## 58.2.6 Port Data Direction Register (GPIOx\_PDDR)

The PDDR configures the individual port pins for input or output.

Address: Base address + 14h offset

### GPIOx\_PDDR field descriptions

| Field       | Description   |
|-------------|---|
| 31–0<br>PDD | <p>Port Data Direction</p> <p>Configures individual port pins for input or output.</p> <p>0 Pin is configured as general-purpose input, for the GPIO function.</p> <p>1 Pin is configured as general-purpose output, for the GPIO function.</p> |

## 58.3 FGPIO memory map and register definition

The GPIO registers are also aliased to the IOPORT interface on the Cortex-M0+ from address 0xF800\_0000.

Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. This aliased Fast GPIO memory map is called FGPIO.

Any read or write access to the FGPIO memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states, except error accesses which complete with one wait state.

### FGPIO memory map

| Absolute address (hex) | Register name                           | Width (in bits) | Access                | Reset value | Section/page                |

| 31–0<br>PDD | <p>Port Data Direction</p> <p>Configures individual port pins for input or output.</p> <p>0 Pin is configured as general-purpose input, for the GPIO function.<br/>1 Pin is configured as general-purpose output, for the GPIO function.</p> |

## 58.4 Functional description

### 58.4.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The Port Data Input registers return the synchronized pin state after any enabled digital filter in the Port Control and Interrupt module. The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

### 58.4.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

| If   | Then   |
|--|--|
| A pin is configured for the GPIO function and the corresponding port data direction register bit is clear. | The pin is configured as an input.   |
| A pin is configured for the GPIO function and the corresponding port data direction register bit is set.   | The pin is configured as an output and the logic state of the pin is equal to the corresponding port data output register. |

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

### 58.4.3 IOPORT

The GPIO registers are also aliased to the IOPORT interface on the Cortex-M0+ from address 0xF800\_0000. Accesses via the IOPORT interface occur in parallel with any instruction fetches and will therefore complete in a single cycle. If the DMA attempts to access the GPIO registers on the same cycle as an IOPORT access, then the DMA access will stall until any IOPORT accesses have completed.

# Chapter 59

## Touch sense input (TSI)

### 59.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The touch sensing input (TSI) module provides capacitive touch sensing detection with high sensitivity and enhanced robustness. Each TSI pin implements the capacitive measurement of an electrode having individual programmable detection thresholds and result registers. The TSI module can be functional in several low-power modes with ultra-low current adder and waking up the CPU in a touch event. It provides a solid capacitive measurement module to the implementation of touch keypad, rotaries, and sliders.

### 59.2 Features

TSI module features included:

- Support for as many as 16 input capacitive touch-sensing pins with individual result registers
- Automatic detection of electrode capacitance change in low-power mode with programmable upper and lower threshold
- Automatic periodic scan unit with different duty cycles for run and low-power modes
- Fully support with Freescale touch-sensing SW library suite the implementation of keypads, rotaries and sliders
- Operation across all low-power modes: WAIT, STOP, VLPR, VLPW, VLPS, LLS, VLLS3, VLLS2, VLLS1
- Capability to wake up MCU from low-power modes.
- Configurable interrupts:

- End-of-scan or out-of-range interrupt
- TSI error interrupts: pad short to  $V_{DD}/V_{SS}$  or conversion overrun
- Automatically compensates for temperature and supply voltage variations within operating parameters
- Stand alone operation not requiring any external crystal even in low-power modes
- Configurable integration of each electrode capacitance measurement from 1 to 4096 periods
- Programmable Electrode Oscillator and TSI Reference Oscillator allowing high sensitivity, small scan time, and low-power functionality.
- Uses only one pin per electrode implementation with no external hardware required

### 59.3 Overview

This section presents an overview of the TSI module. The following figure presents the simplified TSI module block diagram.

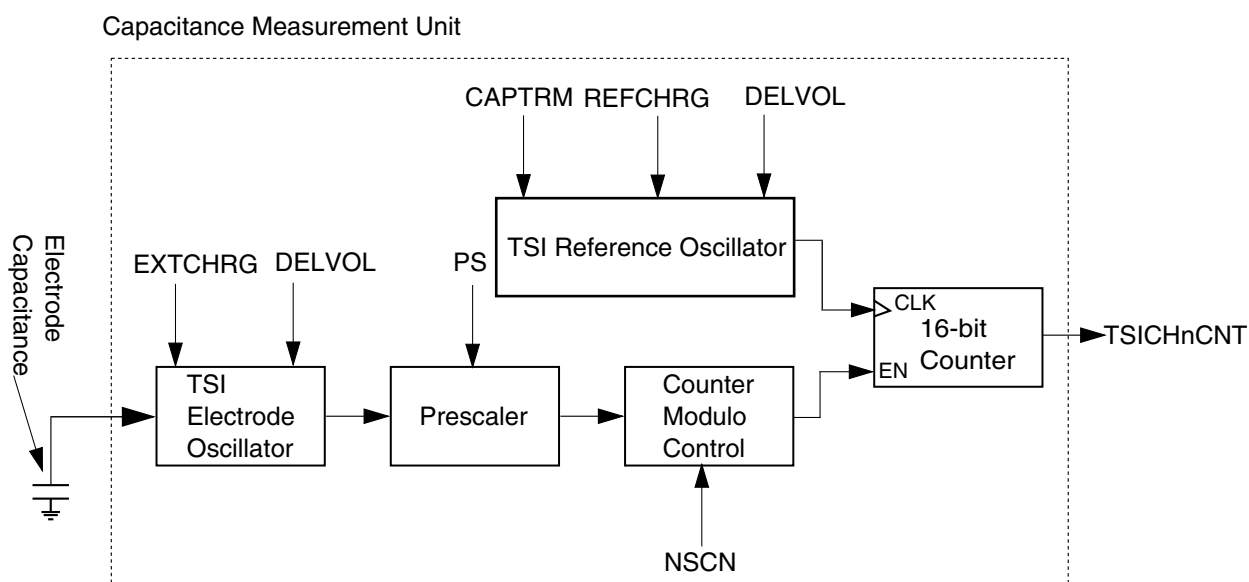

Figure 59-1. TSI block diagram

### 59.3.1 Electrode capacitance measurement unit

The electrode capacitance measurement unit senses the capacitance of a TSI pin and outputs a 16-bit result. This module is based in dual oscillator architecture. One oscillator is connected to the external electrode array and oscillates according to the electrode capacitance, while the other according to an internal reference capacitor. The pin capacitance measurement is given by the counted number of periods of the reference oscillator during a predefined number of electrode oscillations.

The electrode oscillator charges and discharges the pin capacitance with a programmable current source to accommodate several different sizes of electrode capacitances. The electrode oscillator frequency, before being compared to that of the reference oscillator, goes through a prescaler and module counter to decrease its frequency and consecutively increase the measurement resolution and noise robustness.

The following figure presents the simplified block diagram of how the electrode capacitance is measured.

**Figure 59-2. TSI capacitance measurement unit block diagram**

### 59.3.2 Electrode scan unit

This section describes the functionality of the electrode scan unit, which is responsible for triggering the start of the active electrode scan.

The TSI module needs to periodically scan all active electrodes to determine whether a touch event has occurred. The electrode scan unit is responsible for defining two independent scan periods, one for TSI active mode and the other for TSI low-power mode. This independent control allows the application to configure longer scan period

during low-power mode, thereby contributing to smaller average power consumption. The TSI, in low-power mode, has the capability to wake the CPU upon an electrode capacitance change. When the CPU wakes, the TSI enters active mode, and a shorter scan period can provide a faster response time and more robust touch detection. Apart from the periodical mode, the electrode scan unit also allows software triggering of the electrode scans. This feature is very useful for initialization of the touch application for detecting the initial electrode capacitances. This module generates configurable end-of-scan interrupt to indicate the application that all electrodes were scanned. In the event starting a new electrode scan while a previous one is still in progress an overrun error flag is generated.

### 59.3.3 Touch detection unit

The touch detection unit indicates any change in the low-power electrode pin capacitance. The purpose of this module is to wake up only the CPU from low-power modes in the event of a electrode capacitance change. So, if there is no capacitance change in the electrode, the MCU stays in low-power mode indefinitely, while keeping the electrode monitoring, ensuring minimal power consumption.

This module compares the pin capacitance value in the result register with a preconfigured low and high threshold. If the capacitance result register value is outside the ranges defined by upper and lower threshold, the touch detection unit generates an out-of-range flag indicating a pin capacitance change.

The upper and lower threshold values are configurable, allowing the application to select the magnitude of the capacitance change to trigger the out-of-range flag. With the threshold values programmed properly, the application noise level does not cause frequent CPU interrupts, minimizing the CPU usage.

## 59.4 Modes of operation

The TSI module has three operation modes: disabled, active mode, and low-power mode.

**Table 59-1. TSI Module functionality in MCU operation modes**

| MCU operation mode | TSI clock sources           | TSI operation mode when TSIEN = 1 | Functional electrode pins | Required STPE state |
|--------------------|-----------------------------|-----------------------------------|---------------------------|---------------------|
| Run                | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | Don't care          |
| Wait               | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | Don't care          |

*Table continues on the next page...*

**Table 59-1. TSI Module functionality in MCU operation modes (continued)**

| MCU operation mode | TSI clock sources           | TSI operation mode when TSIEN = 1 | Functional electrode pins | Required STPE state pins |
|--------------------|-----------------------------|-----------------------------------|---------------------------|--------------------------|
| Stop               | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | 1                        |
| VLPRun             | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | Don't care               |
| VLPWait            | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | Don't care               |
| VLPStop            | LPOCLK, MSGIRCLK, OSC0ERCLK | Active mode                       | All                       | 1                        |
| LLS                | LPOCLK, VLPOSCCLK           | Low-power mode                    | Determined by PEN[LPSP]   | 1                        |
| VLLS3              | LPOCLK, VLPOSCCLK           | Low-power mode                    | Determined by PEN[LPSP]   | 1                        |
| VLLS2              | LPOCLK, VLPOSCCLK           | Low-power mode                    | Determined by PEN[LPSP]   | 1                        |
| VLLS1              | LPOCLK, VLPOSCCLK           | Low-power mode                    | Determined by PEN[LPSP]   | 1                        |

### 59.4.1 TSI disabled mode

When GENCS[TSIEN] is cleared, the TSI module is disabled, and does not perform any function in any MCU operation mode.

### 59.4.2 TSI active mode

In active mode, the TSI module has its full functionality, being able to scan up to 16 electrodes. The TSI can be in active mode with the MCU in any of the following operational modes: Run, Wait, Stop, VLPR, VLPW, and VLPS.

Three clocks sources can be selected for the TSI module in active mode: LPOCLK, MCGIRCLK, and OSC0ERCLK.

### 59.4.3 TSI low-power mode

The TSI modules enters in low-power mode if the GENCS[STPE] is set to one and the MCU enters in one of the following operational modes: LLS, VLLS1, VLLS2, and VLLS3. In low-power mode, only one selectable pin is active, being able to perform

capacitance measurements. The scan period is defined by GENCS[LPSCNITV] . Two low-power clock sources are available in the TSI low-power mode, LPOCLK, and VLPOSCCLK, being selected by GENCS[LPCLKS].

In low-power mode, the TSI interrupt can also be configured as end-of-scan or out-of-range and the GENCS[TSIEN] must be set in order to generate these interrupts. The TSI interrupt causes the exit of the low-power mode and entrance in the active mode, and the MCU also wakes up.

In low-power mode, the electrode scan unit is always configured to periodical low-power scan.

### 59.4.4 Block diagram

The following figure shows the block diagram of TSI module.<sup>1</sup>

Figure 59-3. TSI block diagram

1. The out-of-range functionality present in the Touch Detection Unit is available only in low-power modes.

## 59.5 TSI signal descriptions

The TSI module has up to 16 external pins for touch sensing. The table below itemizes all the TSI external pins.

**Table 59-2. TSI signal descriptions**

| Signal       | Description  | I/O |
|--------------|--|-----|
| TSI_IN[15:0] | TSI capacitive pins. Switchable driver that connects directly to the electrode pins TSI[15:0] can operate as GPIO pins | I/O |

### 59.5.1 TSI\_IN[15:0]

When TSI functionality is enabled by the PEN[PENn], the TSI analog portion uses corresponding TSI\_IN[n] pin to connect the module with the external electrode. The connection between the pin and the touch pad must be kept as short as possible to reduce distribution capacity on board.

## 59.6 Memory map and register definition

This section presents the touch sensing input module memory map and registers definition.

**TSI memory map**

| Absolute address (hex) | Register name                                    | Width (in bits) | Access | Reset value | Section/ page               |

## 59.7 Functional description

This section provides functional description of the TSI module.

### 59.7.1 Capacitance measurement

The electrode pin capacitance measurement uses a dual oscillator approach. The TSI electrode oscillator has its frequency dependable of the external electrode capacitance and of the TSI module configuration. After going to a configurable prescaler, the TSI electrode oscillator signal goes to the input of the module counter. The time for the module counter to reach its module value is measured using the TSI reference oscillator. The measured electrode capacitance is directly proportional to the time.

**Figure 59-32. Dual electrode capacitance measurement**

### 59.7.1.1 TSI electrode oscillator

The TSI electrode oscillator circuit is illustrated in the following figure. A configurable constant current source is used to charge and discharge the external electrode capacitance. A buffer hysteresis defines the oscillator delta voltage. The delta voltage defines the margins of high and low voltage which are the reference input of the comparator at different times.

**Figure 59-33. TSI electrode oscillator circuit**

The current source applied to the pad capacitance is controlled by the SCANC[EXTCHRG]. The hysteresis delta voltage is defined in the module electrical specifications present in the device data sheet. The figure below shows the voltage amplitude waveform of the electrode capacitance charging and discharging with a programmable current.

**Figure 59-34. TSI electrode oscillator chart**

The oscillator frequency is given by the following equation

$$F_{elec} = \frac{I}{2 * C_{elec} * \Delta V}$$

**Figure 59-35. Equation 1: TSI electrode oscillator frequency**

Where:

I: constant current

C<sub>elec</sub>: electrode capacitance

$\Delta V$ : Hysteresis delta voltage

By this equation, for example, an electrode with  $C_{elec} = 20 \text{ pF}$  and a current source of  $I = 16 \text{ }\mu\text{A}$  and  $\Delta V = 600 \text{ mV}$  has the following oscillation frequency:

$$F_{elec} = \frac{16 \text{ }\mu\text{A}}{2 * 20\text{pF} * 600\text{mV}} = 0.67\text{MHz}$$

**Figure 59-36. Equation 2: TSI electrode oscillator frequency**

The current source is used to accommodate the TSI electrode oscillator frequency with different electrode capacitance sizes.

### 59.7.1.2 Electrode oscillator and counter module control

The TSI oscillator frequency signal goes through a prescaler defined by the GENCS[PS] and then enters in a module counter. GENCS[NSCN] defines the maximum count value of the module counter.

The pin capacitance sampling time is given by the time the module counter takes to go from zero to its maximum value, defined by NSCN. The electrode sample time is expressed by the following equation:

$$T_{cap\_samp} = \frac{PS * NSCN}{F_{elec}}$$

Using Equation 1.

$$T_{cap\_samp} = \frac{2 * PS * NSCN * C_{elec} * \Delta V}{I}$$

**Figure 59-37. Equation 3: Electrode sampling time**

Where:

PS: prescaler value

NSCN: module counter maximum value

I: constant current

$C_{elec}$ : electrode capacitance

$\Delta V$ : Hysteresis delta voltage

By this equation, an electrode with  $C = 20 \text{ pF}$ , a current source of  $I = 16 \text{ }\mu\text{A}$  and  $\Delta V = 600 \text{ mV}$ ,  $PS = 2$ , and  $NSCN = 16$  has the following sampling time:

$$T_{cap\_samp} = \frac{2 * 2 * 16 * 20pF * 600mV}{16\mu A} = 48\mu s$$

### 59.7.1.3 TSI reference oscillator

The TSI reference oscillator has the same topology of the TSI electrode oscillator. The TSI reference oscillator instead of using an external capacitor for the electrode oscillator has an internal reference capacitor.

The TSI reference oscillator has an independent programmable current source controlled by the SCANC[REFCHRG].

The reference oscillator frequency is given by the following equation:

$$F_{ref\_osc} = \frac{I_{ref}}{2 * C_{ref} * \Delta V}$$

**Figure 59-38. Equation 4: TSI reference oscillator frequency**

Where:

$C_{ref}$ : Internal reference capacitor

$I_{ref}$ : Reference oscillator current source

$\Delta V$  : Hysteresis delta voltage

Considering  $C_{ref} = 1.0$  pF,  $I_{ref} = 12$   $\mu$ A and  $\Delta V = 600$  mV, follows

$$F_{ref\_osc} = \frac{12\mu A}{2 * 1.0pF * 600mV} = 10.0MHz$$

## 59.7.2 TSI measurement result

The capacitance measurement result is defined by the number of TSI reference oscillator periods during the sample time and is stored in the TSICHnCNT register.

$$TSICHnCNT = T_{cap\_samp} * F_{ref\_osc}$$

Using Equation 2 and Equation 1 follows:

$$TSICHnCNT = \frac{I_{ref} * PS * NSCN}{C_{ref} * I_{elec}} * C_{elec}$$

**Figure 59-39. Equation 5: Capacitance result value**

In the example where  $F_{ref\_osc} = 10.0MHz$  and  $T_{cap\_samp} = 48$   $\mu$ s,  $TSICHnCNT = 480$

### 59.7.3 Electrode scan unit

This section describes the functionality of the electrode scan unit, which is responsible for triggering the start of the active electrode scan.

The TSI module needs to periodically scan all active electrodes to determine whether a touch event has occurred. The electrode scan unit is responsible for defining two independent scan periods, one for TSI active mode and the other for TSI low-power mode. This independent control allows the application to configure longer scan period during low-power mode, thereby contributing to smaller average power consumption. The TSI, in low-power mode, has the capability to wake the CPU upon an electrode capacitance change. When the CPU wakes, the TSI enters active mode, and a shorter scan period can provide a faster response time and more robust touch detection. Apart from the periodical mode, the electrode scan unit also allows software triggering of the electrode scans. This feature is very useful for initialization of the touch application for detecting the initial electrode capacitances. This module generates configurable end-of-scan interrupt to indicate the application that all electrodes were scanned. In the event starting a new electrode scan while a previous one is still in progress an overrun error flag is generated.

#### 59.7.3.1 Active electrodes

The electrode scan unit is responsible to start the capacitance measurement of all active electrodes. Each electrode pin should be activated by writing a 1 to the respective PEN[PEN] bit.

After an electrode scan is triggered, the electrode scan unit, controls the scanning of all the active electrodes sequentially. It starts the scanning of the electrode pin TSI\_IN[0] and goes sequentially, scanning until it reaches the electrode pin TSI\_IN[15]. The electrode pins that do not have their enable bit (PEN[PEN]) are not scanned and are skipped.

Only one electrode pin is functional in the low-power mode scan and it is defined by the field PEN[LPSP]. In low-power scan mode, the configuration of PEN[PEN] bits are ignored.

### 59.7.3.2 Scan trigger

The scan trigger can be set to periodical scan or software trigger. GENCS[STM] determines the TSI scan trigger mode. If STM = 1, the trigger mode is selected as continuous. If STM = 0, the software trigger mode is selected. In periodic mode, the scan trigger is generated automatically by the electrode scan unit

### 59.7.3.3 Software trigger mode

The software trigger scan is started by writing 1 to the bit GENCS[SWTS]. A single scan of all active electrodes is performed. The software trigger scan can be initiated only by the GENCS[SWTS] bit if the STM = 0. If STM = 1, any write in the GENCS[SWTS] bit is ignored.

### 59.7.3.4 Periodic scan control

The electrode scan unit operates both in TSI active mode and TSI low-power mode. It has a separate scan period control for each one of these modes. It allows the application to controls the trade-off of the scan frequency and the average TSI module power consumption.

Figure 59-40. Periodical scan time chart

#### 59.7.3.4.1 Active mode periodic scan

In active mode periodic scan the scan following clocks can be selected: LPOOSCCLK, MCGIRCLK, and OSC0ERCLK. The field SCANC[AMCLKS] selects the TSI clock source for the active mode scan. The scan period is determined by the SCANC[SMOD] value. SMOD is the module of the counter that determines the scan period.

The following figure presents the scan sequence performed by the TSI module. Every active electrode is scanned sequentially, starting with the TSI\_IN[0] and ending with the TSI\_IN[15] pin, if they are active.

When the electrode scan unit starts a scan sequence, all the active electrodes will be scanned sequentially, with each electrode having a scanned time defined by the GENCS[NSCN]. The counter value is the sum of the total scan times of that electrode.

Figure 59-41. Scan sequence

### 59.7.3.4.2 Low-power mode scan

In low-power periodic scan, the scan period is define by GENCS[LPSCNITV]. The TSI module is enabled only in low-power modes only if GENCS[STPE] is 1.

All electrodes can operate in low power modes except in the low leakage modes. In low leakage modes (LLS, VLLSx) only one electrode pin is functional, it's defined by the bit field PEN[LPSP].

### 59.7.3.4.3 End-of-scan interrupt

The electrode scan unit sets the EOSF flag in the GENCS registers after all the active electrode scan finishes. The EOSF flag generates an end-of-scan interrupt request if it is enabled.. The interrupt is asserted if enabled by GENCS[TSIIE] and GENCS[ESOR].

The GENCS[EOSF] indicates that all active electrode scans are finished and the respective capacitance results are in the TSICHnCNT registers. The GENCS[EOSF] is cleared by writing 1 to it.

#### 59.7.3.4.4 Over-run interrupt

If an electrode scan is in progress and there is a scan trigger, the electrode scan unit generates an over-run error by asserting GENCs[OVRF]. If the TSI error interrupt is active by setting GENCs[ERIE], an interrupt request is asserted. The OVRF flag is cleared by writing 1 to it.

When over-run happens, TSI will enter the un-predictable scanning states, and thus software needs to re-configure the scan period.

### 59.7.4 Touch detection unit

The touch detection unit is responsible for detecting electrode capacitance changes while in low-power mode.

It also detects the occurrence of error with the electrode in the case its capacitance result is 0x0000 or 0xFFFF. The errors can be caused by electrode pin short circuit to  $V_{DD}$  or  $V_{SS}$ , or by electrode capacitances out of the configuration range of the TSI module.

#### 59.7.4.1 Capacitance change threshold

Each TSI pin has the result register TSICHnCNT. In low-power mode, only one electrode can be active. At the end of the low-power active electrode conversion, the touch detection unit compares whether the TSICHnCNT result value is within a configurable range. The comparison range is defined by individual registers: TSICHHnTH, the upper threshold value, and TSICHLnTH, the lower threshold value. If TSICHnCNT happens to be out of the range defined by TSICHLnTH and TSICHHnTH, the GENCs[OUTRGF] flag is set indicating that a capacitance change occurred in the low-power active electrode..

##### 59.7.4.1.1 Out-of-range interrupt

The Out-of-range interrupt is used to wake the CPU from low power modes.

The GENCs[OUTRGF] flag generates a TSI interrupt request if GENCs[TSIIE] is set and GENCs[ESOR] is cleared. With this configuration, after the end-of-electrode scan, the TSI interrupt is requested only when there is a capacitance change. If the low-power electrode capacitance does not vary, the TSI Interrupt does not interrupt the CPU.

### 59.7.4.2 Error interrupt

The GENCS[EXTERF] is set in the case the capacitance result registers, TSICHnCNT, of a TSI pin is either 0 or 0xFFFF, the two possible extreme values. The EXTERF flag generates a TSI Error Interrupt request if the GENCS[ERIE] bit is set.

## 59.8 Application information

After enabling the TSI module for the first time, calibrate all the enabled channels by setting proper high and low threshold value for each active channel. All of the channel dedicated counter values can be read from each counter value register, then the software suite can adjust the threshold based on these values.

Follow proper PCB layout guidelines for board design on electrode shapes, sizes, routes, etc. Visit [www.freescale.com/touch](http://www.freescale.com/touch) for application notes and reference designs.

### 59.8.1 TSI module sensitivity

The TSI module sensitivity is defined by the increment cause in the TSICHnCNT result registers caused by a 1 pF delta in the electrode pin capacitance.

It is given by the following equation:

$$TSI_{sensitivity} = \frac{C_{ref} * I}{I_{ref} * PS * NSCN}$$

For the example provided,  $I_{ref} = 2 \mu A$ ,  $PS = 2$ ;  $NSCN = 16$ ,  $C_{ref} = 1.0 \text{ pF}$  and  $I = 2 \mu A$ , the

$$TSI_{sensitivity} = 0.03125 \text{ pf/count}$$

## 59.9 TSI module initialization

This section provides the recommended initialization sequence for the TSI module.

Prior to enabling TSI module by setting TSI\_GENCS[TSIEN], you must configure other bits first. The pin enable registers are set to select which channels will be sampled. The dual oscillators configuration bits are set to make the scan and conversion more accurate. Also remember not to change the settings while TSI is working in progress. To switch from different scan modes, for instance, you must do a software reset to TSI by disabling and then enabling TSI\_GENCS[TSIEN].

## 59.9.1 Initialization sequence

Freescale TSS library has complete support for TSI, which makes the configuration and application much easier. For detailed information on how to work with TSI and TSS together, visit [www.freescale.com/touchsensing](http://www.freescale.com/touchsensing) to get the application notes for details.

# Chapter 60

## JTAG Controller (JTAGC)

### 60.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

#### 60.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as [Register description](#) for more information about the JTAGC registers.

**Figure 60-1. JTAG (IEEE 1149.1) block diagram**

## 60.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 60-3](#) for a list of supported instructions.
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

## 60.1.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

### 60.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

### 60.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 60.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 60.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 60-1. JTAG signal properties**

| Name | I/O    | Function         | Reset State         | Pull |
|------|--------|------------------|---------------------|------|
| TCK  | Input  | Test Clock       | —                   | Down |
| TDI  | Input  | Test Data In     | —                   | Up   |
| TDO  | Output | Test Data Out    | High Z <sup>1</sup> | —    |
| TMS  | Input  | Test Mode Select | —                   | Up   |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 60.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 60.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 60.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 60.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 60.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 60.3.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                  |   |   |   |
|--------|------------------|---|---|---|
|        | 3                | 2 | 1 | 0 |
| R      | 0                | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |
| Reset: | 0                | 0 | 0 | 1 |

**Figure 60-2. Instruction register**

### 60.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 60.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

The following table describes the device identification register functions.

**Table 60-2. Device identification register field descriptions**

| Field     | Description  |
|-----------|--|
| PRN       | Part Revision Number. Contains the revision number of the part. Value is 0x0.  |
| DC        | Design Center. Indicates the design center. Value is 0x2C.   |
| PIN       | Part Identification Number. Contains the part number of the device. Value is TBD.  |
| MIC       | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.           |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1. |

### 60.3.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 60.4 Functional description

This section explains the JTAGC functional description.

### 60.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 60.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

Figure 60-3. Shifting data through a register

### 60.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 60-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 60.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 60.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

## 60.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 60-3. 4-bit JTAG instructions**

| Instruction            | Code[3:0] | Instruction summary   |
|------------------------|-----------|---|
| IDCODE                 | 0000      | Selects device identification register for shift  |
| EZPORT                 | 0001      | Enables the EZPORT function for the SoC   |
| SAMPLE/PRELOAD         | 0010      | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                                       |
| SAMPLE                 | 0011      | Selects boundary scan register for shifting and sampling without disturbing functional operation  |
| EXTEST                 | 0100      | Selects boundary scan register and applies preloaded values to output pins.<br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| Factory debug reserved | 0101      | Intended for factory debug only   |
| Factory debug reserved | 0110      | Intended for factory debug only   |
| Factory debug reserved | 0111      | Intended for factory debug only   |
| ARM JTAG-DP Reserved   | 1000      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.   |
| HIGHZ                  | 1001      | Selects bypass register and three-states all output pins.<br><b>NOTE:</b> Execution of this instruction asserts functional reset.                   |

*Table continues on the next page...*

**Table 60-3. 4-bit JTAG instructions (continued)**

| Instruction          | Code[3:0] | Instruction summary  |
|----------------------|-----------|--|
| ARM JTAG-DP Reserved | 1010      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.  |
| ARM JTAG-DP Reserved | 1011      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.  |
| CLAMP                | 1100      | Selects bypass register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| EZPORT               | 1101      | Enables the EZPORT function for the SoC  |
| ARM JTAG-DP Reserved | 1110      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.  |
| BYPASS               | 1111      | Selects bypass register for data operations  |

#### 60.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 60.4.4.2 EZPORT instruction

The EZPORT instruction allows for the EZPORT module to program the on-chip flash from a simple 4-pin interface. The JTAGC forces the core into a reset state and forces the EZPORT mode select/chip select low. In this mode, the flash can be programmed through the JTAG test port pins, which are connected to the EZPORT module.

#### 60.4.4.3 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The

sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.

- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

#### 60.4.4.4 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

#### 60.4.4.5 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

#### 60.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

#### 60.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### 60.4.4.8 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

### 60.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

## 60.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS
2. Load the appropriate instruction for the test or action to be performed

# Appendix A

## Release Notes for Revision 3

### A.1 Revision history

#### A.1.1 General changes throughout document

- In the Chip Configuration chapter:
  - Updated the table "Cache regions" in the section "Local memory controller region assignment"
  - Updated the tables "ADC0 channel assignment" and "ADC1 channel assignment"
- In the Clock Distribution chapter:
  - Updated the table "Clock definitions"
  - Updated the table "Clock summary"
  - Updated the figure "TSI low-power clock generation"

#### A.1.2 About This Document chapter changes

- No substantial content changes

#### A.1.3 Introduction chapter changes

- No substantial content changes

#### A.1.4 Chip Configuration chapter changes

- Clarified the "Wake-up Sources" section within the "Low-Leakage Wake-up Unit (LLWU) Configuration" section. Renamed the "LLWU inputs" table to "Wakeup sources for LLWU inputs", removed the multiplexed signals and provided the pin name only. Added a reference to the signal multiplexing table for the individual signal options.
- In ADCx Channel Assignment, updated AD27 and AD29 input signal description.
- Clarified ADC and PGA Reference Options section.
- In LPTMR pulse counter input options section, clarified LPTMR\_CSR[TPS]=11 chip input.
- Added notes to VREF Overview and DAC External Trigger Input Connections sections.

## revision history

|   |
|---|
| <ul style="list-style-type: none"> <li>• Updated ADC and PGA Reference Options section.</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Updated Local memory controller region assignment section.</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Updated ADC0 and ADC1 channel connections for AD21, AD22, and AD23.</li> </ul>   |
| <ul style="list-style-type: none"> <li>• For the "MPU logical bus master assignments" section, corrected the assignments.</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Added note to section "Universal Serial Bus (USB) FS Subsystem"</li> </ul>   |
| <ul style="list-style-type: none"> <li>• Added the note to the section "I2C Configuration" as follows: The Open Drain mode on SDA, SCL pins has to be enabled by setting PORTx_PCRn[ODE] bits.</li> </ul> |
| <ul style="list-style-type: none"> <li>• Changed the instances of MCGPLLCLK to MCGPLL0CLK and MCGPLL1CLK, throughout the chapter, as per applicability.</li> </ul>  |

## A.1.5 Memory Map chapter changes

|   |
|---|
| <ul style="list-style-type: none"> <li>• Added the new section "Read-after-write sequence and required serialization of memory operations"</li> <li>• For the table "System memory map", corrected the access and slave port information for the DRAM controller</li> </ul> |
| <ul style="list-style-type: none"> <li>• Added the area to which SDRAM and Flexbus is aliased to in System Memory map</li> </ul>  |

## A.1.6 Clock Distribution chapter changes

|  |
|--|
| <ul style="list-style-type: none"> <li>• Added note to Debug trace clock section.</li> <li>• In Clock Summary table, added RTC_CLKOUT clock.</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Updated Debug trace clock diagram.</li> </ul>   |
| <ul style="list-style-type: none"> <li>• Updated the "Internal clocking requirements" section.</li> <li>• For the "USB FS OTG Controller clocking" section, added this note: "The MCGFLLCLK does not meet the USB jitter specifications for certification."</li> </ul> |
| <ul style="list-style-type: none"> <li>• Clarified OSC clock names in Clock definitions section.</li> <li>• Updated USB HS controller clock generation section.</li> </ul>   |

## A.1.7 Reset and Boot chapter changes

|   |
|---|
| <ul style="list-style-type: none"> <li>• For the section "Reset pin filter", added more information about the separate LPO filter in the LLWU.</li> </ul>                         |
| <ul style="list-style-type: none"> <li>• For the section "Multipurpose clock generator loss-of-clock (LOC)", updated note about unexpected loss of clock reset events.</li> </ul> |

## A.1.8 Power Management chapter changes

|  |
|--|
| <ul style="list-style-type: none"> <li>• No substantial content changes</li> </ul> |
|--|

## A.1.9 Security chapter changes

- No substantial content changes

## A.1.10 Debug chapter changes

- For the "Debug Components Description" table in the "Introduction", replaced the "JTAG-AP" row with a row for "MDM-AP".

## A.1.11 Signal Multiplexing and Signal Descriptions chapter changes

- No substantial content changes

## A.1.12 PORT changes

- No substantial content changes

## A.1.13 SIM changes

- In the SOPT2 register, updated the FBSL field description.
- In the SCGC5 register, updated the REGFILE field description to be reserved and always 1.
- In the MCR register, updated the ULPICLKOB field description to be reserved.

## A.1.14 RCM changes

- Removed the reference SIM\_COP register.

## A.1.15 PMC changes

- No substantial content changes

## A.1.16 LLWU changes

- No substantial content changes

## A.1.17 MCM changes

- No substantial content changes

## A.1.18 Crossbar switch module changes

- Unused PRS[Mn] fields now show as Reserved.
- PRS register reset value changed to 'X' with footnote.
- All AXBS\_PRS Reserved field reset values changed to 0.
- Corrected AXBS\_CRSn reset value.
- Unimplemented CRS[HPE<sub>n</sub>] bits show as Reserved and have reset value of 0.
- Changed reset values of PRS and CRS registers to 0. Added footnote to refer to chip-specific info.
- Added the note "See the chip-specific crossbar information for the reset value of this register." to the beginning of the Priority Registers Slave (AXBS\_PRS<sub>n</sub>) and Control Register (AXBS\_CRSn) sections.
- Changed occurrences of "AXBS" to "Crossbar Switch."

## A.1.19 MPU module changes

Changed EAR and EDR reset values to 0000\_0000

- Rearranged reset value and reset information in notes of RGD<sub>n</sub>\_WORD2, RGD<sub>n</sub>\_WORD3 and RGDAAC registers

## A.1.20 AIPS module changes

- MPR<sub>n</sub> register(s): Now show correct access-privilege fields based on logical master ID. Added master ID to brief descriptions. Corrected statement re: master ID assignment.
- MPR<sub>n</sub>[MPROT] reset value is now 0b0000 when field is not present (Reserved).
- Changed AIPS\_MPRA reset value to 0x7000\_0000. Non-preset master fields changed to RW.
- Removed list item about dedicated clock enables in Features.
- Removed paragraph about AHB data-phase cycles in Functional description.
- [Memory map/register definition](#) : Incorporated minor editorial changes.

## A.1.21 DMAMUX module changes

|  |
|--|
| <ul style="list-style-type: none"> <li>In section Enabling and configuring sources, the DMA channel number used in the example from channel 2 to channel 1.</li> <li>In DMA channels with periodic triggering capability section, modified Figure DMAMUX triggered channels.</li> <li>Editorial (non-technical) fixes in some sections.</li> </ul> |
| <ul style="list-style-type: none"> <li>Added section Always-enabled DMA sources.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Changed the register name from CHCONFIG to CHCFG.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Updated note in the register description for Channel Configuration register (DMAMUX_CHCFGn) as follows: "Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0)."</li> </ul>                              |
| <ul style="list-style-type: none"> <li>In the section "Enabling and configuring sources," updated DMAMUX_BASE_ADDR in example code.</li> </ul>   |
| <ul style="list-style-type: none"> <li>Changed code examples in "Enabling and configuring sources" section, from #define DMAMUX_BASE_ADDR 0xFC084000/* Example only ! */ to #define DMAMUX_BASE_ADDR 0x40021000/* Example only ! */.</li> </ul>  |

## A.1.22 eDMA module changes

|  |
|--|
| <ul style="list-style-type: none"> <li>In the DMAx_CR section, added "from high to low" in the sentences about round-robin arbitration. For example, "For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority."</li> <li>Updated wording of first paragraph in Dynamic scatter/gather section.</li> </ul>   |
| <p>Changed the following two sentences in the "Error Reporting and handling" section:</p> <ul style="list-style-type: none"> <li>"When a system-bus error occurs, the channel terminates after the read or write transaction, which is already pipelined after errant access, has completed." to "When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA."</li> <li>"The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted." to "The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted."</li> </ul> |
| <p>Added the following sentence to "Dynamic Scatter/Gather" section: It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources.</p>   |
| <ul style="list-style-type: none"> <li>Feature list, added 32-byte to this item (and removed "burst"): Internal data buffer, used as temporary storage to support 16- and 32-byte transfers</li> <li>DMA_TCDn_ATTR[SSIZE], added definition for 101b: 32-byte</li> </ul>   |
| <p>Fixed big-endian ordering of DCHPRI and DCHMID registers. Also updated DCHMID to reflect the correct number of channels.</p>  |
| <ul style="list-style-type: none"> <li>Changed TCDn_CSR[Reserved], TCDn_BITER_ELINKYES[Reserved], and TCD_CITER_ELINKYES[Reserved] to be WOZ instead of ROZ.</li> <li>added image of TCD structure to the beginning of the Memory Map section.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Updated the CR description: changed text from "where priority level 3 is the highest" to be "where priority level 1 is the highest", and changed GRPnPRI bit fields to be 1 bit instead of 2.</li> <li>Changed reset value of DMA_CR from 0000_0000h to 0000_0400h.</li> <li>Updated wording in the register description of DMA_TCD_NBYTES_MLNO, DMA_TCD_NBYTES_MLOFFNO, and DMA_TCD_NBYTES_MLOFFYES for better understanding.</li> <li>DMA_TCD_SLAST register, added the following note to the bit field description: "This register uses two's complement notation; the overflow bit is discarded."</li> <li>DMA_TCDn_DLASTSGA[DLASTSGA]: added bullet about 2's complement.</li> <li>Changed line above "eDMA peak transfer rates" table to be: "This table compares peak transfer rates based n different possible system speeds. Specific chips/devices may not support all system speeds listed."</li> </ul>                                      |

| <ul style="list-style-type: none"> <li>In section "Peak transfer rates", added a note stating "All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information."</li> </ul>   |

### A.1.23 EWM changes

|  |
|--|
| <ul style="list-style-type: none"> <li>Added CTRL[INTEN] bit.</li> <li>Added 'EWM Interrupt' section.</li> </ul> |
|--|

### A.1.24 WDOG changes

|   |
|---|
| Updated the information about LLS for power down mode in Low Power Modes of operation section |
|---|

### A.1.25 MCG changes

|  |
|--|
| <ul style="list-style-type: none"> <li>Updated MCG block diagrams for MCGFFCLK and MCGDDRCLK2X.</li> <li>Updated C1[CLKS] encoding and also updated C10 reset value.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Updated C8[CME1] field description.</li> <li>In section "External Reference Clock", added text "All clock monitors must be disabled before VLPR or VLPW power modes are entered. "</li> </ul> |
| <ul style="list-style-type: none"> <li>For the IRCST field in the MCG Status Register, changed references to the fast clock from "fast clock (2 MHz IRC)" to "fast clock (4 MHz IRC)".</li> </ul>                                    |
| <ul style="list-style-type: none"> <li>Updated the bitfield access of ATMF and LOCS0 in the MCG_SC register</li> </ul>   |

### A.1.26 OSC changes

- No substantial content changes

### A.1.27 RTC Oscillator changes

- No substantial content changes

### A.1.28 LMEM changes

- Added "Special considerations when using the cache with low power modes" section.

Deleted the section, "Special considerations when using the cache with low power modes."

### A.1.29 FMC changes

- No substantial content changes

### A.1.30 FTFE changes

- Correct Flash Configuration Field Offset Address for VFYKEY command input

### A.1.31 EzPort changes

In "Command descriptions" section, added timing diagrams for each command sequence.

### A.1.32 NFC changes

- Editorial changes.
- [Row address \(NFC\\_RAR\)](#) : Swapped the positions of the RB $n$  and CS $n$  fields.
- [NAND Flash Boot](#) : Deleted "See the Chip Configuration details for what the processor does after this" from step 4.

### A.1.33 FlexBus changes

|   |
|---|
| <ul style="list-style-type: none"> <li>Minor editorial changes and reorganization of sections:             <ul style="list-style-type: none"> <li>Many sections were divided into multiple subsections.</li> <li>Changed "Overview" section name to "Definition."</li> <li>Moved data from signal description subsections into the signal description table.</li> <li>Removed "Chip Select Operation" section.</li> <li>Moved "Modes of operation" section to "Functional description" section.</li> <li>Combined "Bus Cycle execution" and data transfer cycle states sections into the "Data transfer states" section.</li> </ul> </li> </ul> |
| For little endian devices : Revised figure "Connections for External Memory Port Sizes (CSCRn[BLS]=1)": Added byte enable lines for each port size (included adding overbars to BE signals).  |
| <ul style="list-style-type: none"> <li>Changed the Note in the CSMR[V] bitfield description to say: "At reset, FB_CS0 will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed."</li> </ul>   |
| <ul style="list-style-type: none"> <li>Combined CSCR[PS] 10b and 11b options into 1X since they had the same bit field definition.</li> </ul>   |
| <ul style="list-style-type: none"> <li>Added FB_TBST trace to 6 burst timing diagrams</li> <li>Improved 2 diagrams ["Connections for external memory port sizes (CSCRn[BLS] = 0)", "Connections for external memory port sizes (CSCRn[BLS] = 1)"]</li> </ul>  |
| In all 12 Read timing diagrams, updated FB_BE/BWEn signal to show BEM=1 and BEM=0.  |

### A.1.34 CRC changes

|  |
|--|
| Changed the name of the CRC_CRC register to the CRC_Data register      |
| Editorial change in the section "CRC initialization/reinitialization." |

### A.1.35 MMCAU changes

|  |
|--|
| <ul style="list-style-type: none"> <li>No substantial content changes</li> </ul> |
|--|

### A.1.36 RNGA chapter changes

|   |
|---|
| <ul style="list-style-type: none"> <li>Updated description of RNGA Control Register, RNG_CR[HA] field, RNG_SR[OREG_LVL] field, RNG_SR[ERRI] field, RNG Output Register, RNG_ER[EXT_ENT] field</li> <li>Updated RNGA block diagram</li> <li>Updated description of RNGA Control Block</li> <li>Updated description of Initialization/application information.</li> </ul> |
| In "Overview," updated bulleted item from "Mouse and keyboard motions, or equivalent if being used on a cell phone or PDA" to "Real-time system inputs that can be characterized as 'random'."  |

### A.1.37 Drylce changes

- No substantial content changes

### A.1.38 ADC changes

- In ADC Signal Descriptions section: Added note to refer to chip configuration for inputs supported.
- Updated the bit field description of CFG1[ADICLK] to Bus Clock/2
- Editorial changes
- Changed bitfield access of ADC\_SC3[CALF] to w1c (write 1 to clear).

### A.1.39 CMP changes

- Updated CMPx\_CR1[PMODE] field description.
- Updated SE value in 'Sampled, Filtered (# 4B): Sampling point internally derived' diagram.
- Added Reserved field (was previously PSTM, Pass Through Mode Enable) in CMP\_MUXCR register

### A.1.40 DAC changes

- Replace introduction topic content.

### A.1.41 VREF changes

- No substantial content changes

### A.1.42 PDB changes

In the memory map, changed Channel n Status Register access to R/W.

- Updated the DAC trigger module in PDB Block Diagram
- Added the following sentence to section "PDB pre-trigger and trigger outputs":  
 "When the ADC receives the rising edge of the trigger, the ADC will start conversion as the precondition determined by pre-triggers."

## A.1.43 FTM changes

- |  |
|--|
| <ul style="list-style-type: none"> <li>• Corrected the figure "Example of the Prescaler Counter".</li> </ul>   |
| <ul style="list-style-type: none"> <li>• For section "Filter for Input Capture mode", removed the phrase "5-bit" in references to the counter and clarified when the input signal is validated.</li> </ul> |

## A.1.44 PIT module changes

- |  |
|--|
| <ul style="list-style-type: none"> <li>• In MCR, standardized access type for Reserved fields to read-only</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Added to registers header: "Timer Channel n" table and all content.</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Deleted "Timer Channel n / RTI Channel" table because the same information is in the more comprehensive "PIT memory map" table.</li> <li>• RTI_TCRTL register:             <ul style="list-style-type: none"> <li>• Deleted CHN bit.</li> <li>• Changed description of the TIE bit to show RTI_TFLG[TIF].</li> <li>• Changed bit map of TEN bit to show "RTI Timer".</li> </ul> </li> </ul> |
| <ul style="list-style-type: none"> <li>• Introduction section. For SOCs that use PIT pulses to trigger DMA, added DMA text to sentence "The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels."</li> <li>• Features section. For SOCs that use PIT pulses to trigger DMA, added DMA text to bullet "Ability of timers to generate DMA trigger pulses"</li> </ul>                        |
| <ul style="list-style-type: none"> <li>• MCR[MDIS or Reserved] bit.             <ul style="list-style-type: none"> <li>• Changed Reserved access to R/W.</li> </ul> </li> </ul>  |
| <ul style="list-style-type: none"> <li>• TFLG, TCTRL, CVAL, and LDVAL registers:             <ul style="list-style-type: none"> <li>• For implementations that use 6 channels, 6 channels can now be shown.</li> </ul> </li> <li>• Removed "-RTI" from chapter title</li> </ul>  |
| <ul style="list-style-type: none"> <li>• PIT_TCTRLn[CHN] description             <ul style="list-style-type: none"> <li>• Changed sentence to read "Timer 0 cannot be chained."</li> </ul> </li> </ul>   |
| <ul style="list-style-type: none"> <li>• For the third bullet updated 1 hour to 1 minute in <a href="#">Example configuration for chained timers</a>.</li> </ul>   |
| <ul style="list-style-type: none"> <li>• Added information about register access level at the end of each register description</li> </ul>  |

## A.1.45 LPTMR changes

- |   |
|---|
| <p>Updated the following sentence: "If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set."</p> |
|---|

## A.1.46 CMT changes

- |  |
|--|
| <ul style="list-style-type: none"> <li>• No substantial content changes</li> </ul> |
|--|

## A.1.47 RTC changes

- Swapped the TDTL and TDTH fields in the RTC\_TTR register.

## A.1.48 ENET module changes

- Added Reference clock subsection in Functional description section.
- -
- Added STAT\_SECTION\_EMPTY field to RSEM register in Memory Map section.
- Added AVB features included new regs RDAR1/2, TDAR1/2, RCMR1, Rate limiting traffic shaping support topic.
- Added DMAnCFG regs
- Removed 'u' reset values from register section.
- Clarified descriptions for TTL and header checksum in ipv4 checksum datagram format topic
- Registers topic: Replaced ETHER\_EN with ETHEREN for consistency. Added bit values and note to TFRW register.
- Added RGMII\_REF\_CLK to external signals topic.
- Added 1G bandwidth limitation to features topic.
- Added QOS\_SCHEME register topic. Corrected value in example 2 in DMACFG[IDLE\_SLOPE] register description. Added RX\_FLUSHn fields to EIR reg. Added missing fields to EIMR to match EIR. Added bitfieldaccess element to eimr[rxflush\_0]. Changed EIMR[8:13] to RW with note added to description. Changed EIMR[24:31] from W1C to RW. Added better descriptions to RXFLUSH fields in EIR.
- Added round-robin mux and QoS select mux to Transmit arbitration scheme figure.
- Added note to clarify restriction on legacy description use.
- Removed EIR[RXFLUSH\_0] and EIRM[RXFLUSH\_0] fields and QOS\_SCHEME register.
- Added note to ENET\_EIR register description about use in enhanced mode.
- In Enhanced transmit buffer descriptor (TxBD) table, for offset + 8 entry in , changed "Generate interrupt" to "Generate interrupt flags".
- In [External signal description](#), replaced '—' with "1588\_TMRn" in 1588\_TMRn row and RGMII column.
- Tables for enhanced and legacy buffer descriptors have been modified to show correct byte order for little endian devices.
- Improved register descriptions in Receive FIFO and Transmit FIFO sections.
- Added Statistic Event Counter registers, 0X0200-0x02E0, to Memory map/register definition section and removed Statistic event counters section.
- Corrected 1588EN to EN1588 in [IEEE 1588 functions](#).
- Updated descriptions for RSEM, RSFL, RSEM, RAEM, TSEM, TAEM, and TAFL registers.
- Corrected first note in [Legacy buffer descriptors](#).
- Removed redundant content from RSFL[RX\_SECTION\_FULL] description.
- Corrected widths of Reserved and Flags fields in TCP header fields table.
- Added note to ECR[ETHEREN] description.
- In Ethernet MAC features, changed operating speeds from 25 MHz to 2.5/25 MHz and spelled out AVB.
- In figure "MAC frame format overview" and "VLAN-tagged MAC frame format overview," corrected position of Frame Length brace.
- Changed R/W access of some of the reserved fields in: TDAR, ATCR, .
- Removed note from ENET\_ATCR register description. Added note and "This field automatically clears to 0 after the command completes." to ATCR[CAPTURE] and ATCR[RESTART] descriptions.
- Changed "this register to 0x0000\_0004" to "MII\_SPEED to 0x4" in MSCR register description.
- Added Warning to [Adjustable Timer Control Register \(ENET\\_ATCR\)](#) register CAPTURE and RESTART field descriptions.

## revision history

|  |
|--|
| <ul style="list-style-type: none"> <li>In <a href="#">TFWR</a> : Bit field values now show only valid values. Removed note that referred reader to chip-specific information.</li> <li>In <a href="#">Sleep mode</a> : Replaced ambiguous use of "core" with "MAC".</li> <li>In <a href="#">Adjustable timer module</a> : Removed sentence referring to time-stamp clock source.</li> <li>Removed Receive Flushing topic; does not apply to single-queue ENET.</li> <li>Removed reference to DMAnCFG register in <a href="#">Legacy buffer descriptors</a>.</li> <li>Added value descriptions to ENET_MIBC register fields.</li> </ul>   |
| <ul style="list-style-type: none"> <li>Added <a href="#">Input Capture and Output Compare</a>.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Corrected field width of ENET_MRBRn[R_BUF_SIZE].</li> </ul>   |
| <ul style="list-style-type: none"> <li>Corrected access type of ENET_ATCR[Reserved ] to WOO and added note to its description that it must be written with one.</li> </ul>   |
| <ul style="list-style-type: none"> <li>In <a href="#">MDIO clause 22 frame format</a> changed "IEEE803.2" to "IEEE 802.3".</li> <li>Made improvements to <a href="#">Block diagram</a> figure.</li> </ul>  |
| <ul style="list-style-type: none"> <li><a href="#">Memory map/register definition</a> : Added statement regarding allowed accesses width to registers and made editorial changes.</li> <li><a href="#">Transmit Inter-Packet Gap (ENET_TIPG)</a> : Corrected description of IPG field.</li> <li><a href="#">Inter-packet gap (IPG)</a> : Corrected text regarding IPG values.</li> <li>Removed sentences regarding register reset/initialization in <a href="#">Physical Address Lower Register (ENET_PALR)</a> and <a href="#">Physical Address Upper Register (ENET_PAUR)</a>.</li> <li>Improved descriptions of statistics register fields.</li> <li>Removed Receive Parser block from <a href="#">Figure 47-109</a>.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Updated descriptions for <a href="#">Frames Received OK Statistic Register (ENET_IEEE_R_FRAME_OK)</a> and <a href="#">Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)</a>.</li> <li>Changed occurrences of DMA to uDMA, where appropriate, for clarity.</li> <li>Added note to ENET_IEEE_T_FRAME_OK[COUNT ] description.</li> <li>Added note to ENET_IEEE_R_OCTETS_OK[COUNT ] description.</li> <li>Added receive and transmit FIFO depths to <a href="#">FIFO thresholds</a>.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Added description of uDMA to <a href="#">Overview</a>. Replaced "DMA" with "uDMA" in <a href="#">Transmit FIFO Watermark Register (ENET_TFWR)</a> and <a href="#">Soft reset</a>.</li> <li>Added descriptions for RMON_T_DROP, IEEE_T_DROP, IEEE_T_SQE, and RMON_R_RESVD_0 registers.</li> <li>Added new IEEE 802.3 Clause 45 content: <ul style="list-style-type: none"> <li>Added this feature to <a href="#">Ethernet MAC features</a>.</li> <li>Modified ENET_MMFR field descriptions.</li> <li>Changed content and title of <a href="#">MDIO clause 22 frame format</a>.</li> <li>Added <a href="#">MDIO clause 45 frame format</a>.</li> </ul> </li> <li>Changed full register names of RMON_T_DROP, IEEE_T_DROP, and RMON_R_RESVD_0 to "Reserved Statistic Register".</li> <li>In ENET_TCSRn[TMODE] description changed "1100 Reserved" to "110X Reserved".</li> </ul> |
| <ul style="list-style-type: none"> <li>Changed <a href="#">Reserved Statistic Register (ENET_RMON_T_DROP)</a> and <a href="#">IEEE_T_DROP Reserved Statistic Register (ENET_IEEE_T_DROP)</a> to have single, 32-bit, Reserved fields.</li> </ul>   |

## A.1.49 USB full speed OTG controller changes

|  |
|--|
| <ul style="list-style-type: none"> <li>In "Host mode operation examples", corrected the "Data toggle" in the first bullet of Step 11 for the "To complete a control transaction to a connected device" procedure.</li> </ul>   |
| <ul style="list-style-type: none"> <li>In the "Buffer descriptor fields" table within the "Buffer Descriptors (BDs)" section, added information to the description of the BDT_STALL bit.</li> </ul>  |
| <ul style="list-style-type: none"> <li>In "OTG and Host mode operation" section, changed the following sentence, "Support is provided for ISO transfers, but the number of ISO streams that can be practically supported is affected by the interrupt latency of the processor servicing the token during interrupts from the SIE," to "Support is provided for ISO transfers, but the number of ISO streams that can be practically supported is affected by the interrupt latency of the processor servicing the Token Done interrupts from the SIE."</li> </ul> |

|   |
|---|
| <ul style="list-style-type: none"> <li>• Under USB_ENDPT register description, added table, "Endpoint enable and direction control," to clarify functioning of EPCTLDIS, EPRXEN, and EPTXEN bits.</li> <li>• Changed ADDINFO[IRQNUM] description to "Reserved; should always have the value zero."</li> </ul> |
| Added new topic under "Functional description": "On-chip transceiver required external components."   |
| Corrected range of USB SRAM for use in Keep Alive mode from 256 bytes to 512 bytes.   |

### A.1.50 USBDCD changes

|  |
|--|
| <ul style="list-style-type: none"> <li>• No substantial content changes</li> </ul> |
|--|

### A.1.51 USB VREG changes

|   |
|---|
| <ul style="list-style-type: none"> <li>• No substantial content changes</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Removed the number specified for the STANDBY regulator output load current.</li> <li>• Corrected the figure "Ideal Relation Between the Regulator Output and Input Power Supply".</li> </ul> |

### A.1.52 USB high speed OTG controller changes

|  |
|--|
| <ul style="list-style-type: none"> <li>• No substantial content changes</li> </ul> |
|--|

### A.1.53 FlexCAN module changes

|   |
|---|
| <ul style="list-style-type: none"> <li>• Added a new section, "Clock domain relations"</li> </ul>   |
| <ul style="list-style-type: none"> <li>• In table in description of CTRL2[RFFN] field: Added footnote to heading of second-to-last column</li> </ul>  |
| <ul style="list-style-type: none"> <li>• In FlexCAN module features section, added bullet "Compliant with the ISO 11898-1 standard".</li> <li>• Updated CAN engine clocking scheme figure of Protocol timing section.</li> <li>• Updated table title from "CAN standard compliant bit time segment settings" to "Bosch CAN 2.0B standard compliant bit time segment settings".</li> </ul>   |
| <ul style="list-style-type: none"> <li>• In <a href="#">Module Configuration Register (CAN_MCR)</a> <ul style="list-style-type: none"> <li>• Changed reserved field access from read/write to read-only and always read as 0:           <ul style="list-style-type: none"> <li>• <a href="#">Reserved</a></li> <li>• <a href="#">Reserved</a></li> </ul> </li> </ul> </li> <li>• In description of in added "error" to first sentence: "Disables completely the memory error detection and correction mechanism."</li> <li>• In description of in added: "The two least significant bits of this field always read as 0."</li> <li>• Previous errata e7724 integrated into the RM: Changed access for and from read/write to read-only</li> </ul> |
| <ul style="list-style-type: none"> <li>• <a href="#">Interrupts</a> <ul style="list-style-type: none"> <li>• Edited text and standardized format of references to registers</li> </ul> </li> </ul>  |

## A.1.54 SPI module changes

|   |
|---|
| <ul style="list-style-type: none"> <li>In 'Transmit FIFO Fill Interrupt or DMA Request' section, added note on using TFFF flag.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Added links to corresponding functional description in the Delay fields in CTAR register.</li> <li>Renamed DSICR to DSICR0.</li> <li>Updated EOQ interrupt request description.</li> <li>Added SPITCF and DSITCF interrupt request descriptions and updated corresponding bit fields in SR register.</li> <li>Updated DIS_TXF and DIS_RXF bit field descriptions in MCR register.</li> <li>Updated 'Sample MSC downstream transmission using ITSB mode' diagram.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Updated Features section about 8 extended CTAR registers; programmable serial frame size upto 64 bits; DMA Support for CMDFFF and DDIF; Interrupt Support for CMDFFF, CMDTCF, TFIWF.</li> <li>Added XSPI field to MCR register.</li> <li>Updated CTAR[FMSZ] field description. Added FMSZ6 field to CTAR_Slave.</li> <li>DSPI_SR Register : Updated TFFF description. Added BSYF, CMDFFF, CMDTCF and TFIWF fields.</li> <li>DSPI_RSER register: Added fields CMDFFF_RE, CMDTCF_RE, TFIWF_RE, CMDFFF_DIRS and DDIF_DIRS.</li> <li>Updated PUSHMaster, PUSHSlave and TXFRn Register Descriptions.</li> <li>Appended 0 to following register names: SDR, ASDR, COMPR, DDR, SSR, DIMR, DPIR. Also updated their register descriptions. Added FMSZ[5] bit to DSICR0. Added DSI64 and TSBCNT[5] to DSICR1 register.</li> <li>Added SDR1, ASDR1, COMPR1, DDR1, SSR1, PISR4-7, DIMR1, DPIR1, CTARE, SREX Registers.</li> <li>Updated DSPI Memory Map.</li> <li>Updated PUSH[CONT] bit description.</li> <li>Updated Stop Mode, Module Disable Mode descriptions under Power Saving Features.</li> <li>Updated Following figures : Block Diagram, DSI Serialization, DSI Deserialization, TSB Downstream Frames, TSB Data Frame Format for MSC Dual Receiver Operation, TSB Data Frame Format for MSC Dual Receiver Operation.</li> <li>Updated "Deserial Serial Interface (DSI) configuration" functional description to mention about the new DSI64 Mode and its usage.</li> <li>Added a Note to "Multiple Transfer Operation (MTO)".</li> <li>Updated "Combined Serial Interface (CSI) configuration" to include effects of the new XSPI and DSI64 modes.</li> <li>Added "Command FIFO Fill Interrupt or DMA Request", "Transmit FIFO Invalid Write Interrupt Request", Command Transfer Complete Interrupt Request", "Deserialized Data Match DMA Request" to "Interrupts/DMA Requests".</li> <li>Added "Address Calculation for first-in-entry and last-in-entry in the CMD FIFO.</li> </ul> |
| <ul style="list-style-type: none"> <li>Modified Async Clocking Scheme and CMDTCF Feature Descriptions</li> <li>Updated descriptions of the following bitfields: MCR[MDIS], CTAR[FMSZ], SR[CMDTCF], SR[TFFF], PUSH[PE_MASC], PUSH[PP_MCSC]</li> <li>Updated register description for PUSHSlave and RXFRx</li> <li>Changed CTAR_SLAVE[FMSZ6] to CTAR_SLAVE[FMSZ5]</li> <li>Updated mention of system clock to protocol clock at all places appropriate</li> </ul>   |
| <ul style="list-style-type: none"> <li>Revised the field description of DSPI_CTARn_SLAVE[FMSZ]</li> <li>In the Combined Serial Interface (CSI) Configuration, revised the note</li> <li>In the Timed Serial Bus (TSB) section, revised the figure</li> <li>Editorial updates</li> <li>Notes added in DSPI_CTARn_SLAVE[CPOL] bit description</li> <li>Notes added in DSPI_CTARn[CPOL] bit description</li> <li>In DSPI_MCR changed <a href="#">Reserved</a> bit from read-only to read/write</li> </ul>  |
| <ul style="list-style-type: none"> <li>Included two topics <a href="#">Modified SPI Transfer Format (MTFE = 1, CPHA = 0)</a> and <a href="#">Modified SPI Transfer Format (MTFE = 1, CPHA = 1)</a>.</li> </ul>  |
| <ul style="list-style-type: none"> <li>Reduced bit width of SPI_CTARn_SLAVE [FMSZ] from 5 to 4.</li> <li>In RSER register, added note "Always write the reset value to this field." to Reserved bits.</li> <li>In PUSH register, added note "Always write the reset value to this field." to Reserved bits.</li> </ul>  |
| <ul style="list-style-type: none"> <li>In <a href="#">Memory Map/Register Definition</a> section, added 'RXFRn' word.</li> <li>In <a href="#">Module Configuration Register (SPI_MCR)</a> register, added "Refer to the chip-specific..." sentence in PCSIS bit.</li> <li>In <a href="#">PUSH TX FIFO Register In Master Mode (SPI_PUSH)</a> register, added "Refer to the chip-specific..." sentence in PCS bit.</li> </ul>  |

- In [Continuous Serial Communications Clock](#) section, updated the second sentence in second paragraph as 'Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low'.
- Editorial updates.

## A.1.55 I2C changes

- In description of F[ICR], added new final sentence and table containing examples of MULT and ICR field settings.
- In description of C2[SBRC], added sentence describing an example of a "very fast" I2C mode.
- In "Clock stretching" section, added new final sentence to clarify the effect of clock stretching.
- Clarified that the reserved bit 7 of the Programmable Input Glitch Filter register can be written but that writing it has no effect.
- In the "SCL high timeout" section, removed references to detection of a HIGH timeout after a STOP condition appears on the bus.
- Reorganized the "Address matching wakeup" section, and added in the final note the sentence "The main purpose is not communication."
- Reorganized the "Address matching" section, and clarified the sources of a 7-bit and 10-bit address, including the involvement of ADEXT and AD[10:8] in Control Register 2.
- In "Address matching wakeup" section: Combined the two notes and expanded the note text
- In the Status register: Added added a new note to the description of the RAM bit
- In the "Address matching wakeup" section: Clarified the note text
- In "I2C divider and hold values" section: Added note preceding the table, and shaded table cells containing ICR values of 00h to 0Fh
- In Inter-Integrated Circuit (I2C) chapter, added new section " I2C module address matching to wake the device from stop mode"
- Updated and clarified the flowchart figure "Typical I2C SMBus interrupt routine".
- Used the wording "I2C module clock" instead of "bus clock" in the register definitions and the "Programmable input glitch filter" section.
- Updated in the statements of register fields S[IAAS], S[RAM], C2[RMEN], RA[RAD] and the section "Address matching", to clarify that the Range Address register is only meaningful when the C2[RMEN] bit is set.
- Added notes in the sections "Address matching wake-up".
- No substantial content changes.
- Added the handling of START/STOP interrupt in the ISR flowchart [Typical I2C interrupt routine](#).

## A.1.56 UART changes

- Updated S2[MSBF], S2[RXINV], C3[TXINV] and C7816[INIT] register bit field descriptions to mention that Initial Character Detect feature can only be used in TTYPE = 0 mode.
- Updated Initial Characters Section in 7816 Functional Description.
- Updated Protocol T=0 Section in 7816 Functional Description.
- Updated IE[ISDIE] register bit field description.
- Added bits CFIFO[RXOFF] and SFIFO[RXOF] which were missing. These are legacy register bits.
- Updated the section "RXEDGIF description"
- Added reference to the "Hardware Flow Control" section, in the field description for UART\_MODEM[RXRTSE]

## A.1.57 SDHC changes

- No substantial content changes

## A.1.58 I2S/SAI changes

- For both TCSR[TE] and RCSR[RE] fields, clarified the description for field value of 1.
- In "Introduction" section: Clarified support for TDM mode.
- Revised descriptions of BCS and BCI fields in TCR2.
- Clarified descriptions of TCE field in TCR3 and RCE field in RCR3.
- In "FIFO pointers" section: Clarified 8-bit and 16-bit accesses to the FIFOs.
- In "Frame sync configuration" section: Clarified various configuration options.
- Added "Integrated Interchip Sound (I2S)" to the main title to clarify the module's support for this standard.
- Removed references to "received" from description of TCR4[MF]
- Removed references to "transmitted" from description of RCR4[MF]
- In the descriptions of TCR2[MSEL] and RCR2[MSEL], added this Note: "Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option."
- In the "Bit clock" section of the "Clocking" section, added a new final paragraph: "If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously."

## A.1.59 GPIO changes

- No substantial content changes

## A.1.60 TSI changes

- No substantial content changes

## A.1.61 JTAGC module changes

- Removed arrow from TDI to TAP instruction register in block diagram figure
- Added EZPORT row to 4-bit JTAG instructions table with Code 1101
- In the General JTAG instructions table, updated the Instruction summary cells to emphasize which instructions assert functional reset.
